The MCM69P819 is a 4M bit synchronous fast static RAM designed to provide a burstable, high performance, secondary cache for the PowerPC™ and other high performance microprocessors. It is organized as 256K words of 18 bits each. This device integrates input registers, an output register, a 2–bit address counter, and high speed SRAM onto a single monolithic circuit for reduced parts count in cache data RAM applications. Synchronous design allows precise cycle control with the use of an external clock (K).

Addresses (SA), data inputs (DQx), and all control signals except output enable (G) and linear burst order (LBO) are clock (K) controlled through positive–edge–triggered noninverting registers.

Bursts can be initiated with either ADSP or ADSC input pins. Subsequent burst addresses can be generated internally by the MCM69P819 (burst sequence operates in linear or interleaved mode dependent upon the state of LBO) and controlled by the burst address advance (ADV) input pin.

Write cycles are internally self–timed and are initiated by the rising edge of the clock (K) input. This feature eliminates complex off–chip write pulse generation and provides increased timing flexibility for incoming signals.

Synchronous byte write (SBx), synchronous global write (SGW), and synchronous write enable (SW) are provided to allow writes to either individual bytes or to all bytes. The two bytes are designated as “a” and “b”. SBa controls DQa and SBb controls DQb. Individual bytes are written if the selected byte writes SBx are asserted with SW. All bytes are written if either SGW is asserted or if all SBx and SW are asserted.

For read cycles, pipelined SRAMs output data is temporarily stored by an edge–triggered output register and then released to the output buffers at the next rising edge of clock (K).

The MCM69P819 operates from a 3.3 V core power supply and all outputs operate on a 2.5 or 3.3 V power supply. All inputs and outputs are JEDEC standard JESD8–5 compatible.

- MCM69P819–3.5: 3.5 ns Access/6 ns Cycle (166 MHz)
  MCM69P819–3.8: 3.8 ns Access/6.7 ns Cycle (150 MHz)
  MCM69P819–4: 4 ns Access/7.5 ns Cycle (133 MHz)
- 3.3 V + 10%, – 5% Core Power Supply, 2.5 V or 3.3 V I/O Supply
- ADSP, ADSC, and ADV Burst Control Pins
- Selectable Burst Sequencing Order (Linear/Interleaved)
- Single–Cycle Deselect Timing
- Internally Self–Timed Write Cycle
- Byte Write and Global Write Control
- PB1 Version 2.0 Compatible
- JEDEC Standard 119–Pin PBGA and 100–Pin TQFP Packages

PBGA PIN DESCRIPTIONS

Pin Locations	Symbol	Type	Description
4B	$\overline{ADSC}$	Input	Synchronous Address Status Controller: Active low, interrupts any ongoing burst and latches a new external address. Used to initiate a READ, WRITE, or chip deselect.
4A	$\overline{ADSP}$	Input	Synchronous Address Status Processor: Active low, interrupts any ongoing burst and latches a new external address. Used to initiate a new READ, WRITE, or chip deselect (exception — chip deselect does not occur when ADSP is asserted and SE1 is high).
4G	$\overline{ADV}$	Input	Synchronous Address Advance: Increments address count in accordance with counter type selected (linear/interleaved).
(a) 6D, 7E, 6F, 7G, 6H, 7K, 6L, 6N, 7P (b) 1D, 2E, 2G, 1H, 2K, 1L, 2M, 1N, 2P	DQx	I/O	Synchronous Data I/O: “x” refers to the byte being read or written (byte a, b).
4F	$\overline{G}$	Input	Asynchronous Output Enable Input: Low — enables output buffers (DQx pins). High — DQx pins are high impedance.
4K	K	Input	Clock: This signal registers the address, data in, and all control signals except G and LBO.
3R	$\overline{LBO}$	Input	Linear Burst Order Input: This pin must remain in steady state (this signal not registered or latched). It must be tied high or low. Low — linear burst counter (68K/PowerPC). High — interleaved burst counter (486/i960/Pentium).
2A, 3A, 5A, 6A, 3B, 5B, 2C, 3C, 5C, 6C, 2R, 6R, 2T, 3T, 5T, 6T	SA	Input	Synchronous Address Inputs: These inputs are registered and must meet setup and hold times.
4N, 4P	SA1, SA0	Input	Synchronous Address Inputs: These pins must be wired to the two LSBs of the address bus for proper burst operation. These inputs are registered and must meet setup and hold times.
5L, 3G (a) (b)	SBx	Input	Synchronous Byte Write Inputs: “x” refers to the byte being written (byte a, b). SGW overrides SBx.
4E	SE1	Input	Synchronous Chip Enable: Active low to enable chip. $\overline{\text{Negated}}$ high — blocks ADSP or deselects chip when ADSC is asserted.
2B	SE2	Input	Synchronous Chip Enable: Active high for depth expansion.
6B	$\overline{SE3}$	Input	Synchronous Chip Enable: Active low for depth expansion.
4H	$\overline{SGW}$	Input	Synchronous Global Write: This signal writes all bytes regardless of the status of the SBx and SW signals. If only byte write signals SBx are being used, tie this pin high.
4M	$\overline{SW}$	Input	Synchronous Write: This signal writes only those bytes that have been selected using the byte write SBx pins. If only byte write signals SBx are being used, tie this pin low.
4C, 2J, 4J, 6J, 4R	V_{DD}	Supply	Core Power Supply.

NOTES:
1. X = Don't Care. 1 = logic high. 0 = logic low.
2. Write is defined as either 1) any SBx and SW low or 2) SGW is low.
3. G is an asynchronous signal and is not sampled by the clock K. G drives the bus immediately (t_{GLQX}) following $\overline{G}$ going low.
4. On write cycles that follow read cycles, G must be negated prior to the start of the write cycle to ensure proper write data setup times. $\overline{G}$ must also remain negated at the completion of the write cycle to ensure proper write data hold times.
5. This read assumes the RAM was previously deselected.

NOTES:
1. Permanent device damage may occur if ABSOLUTE MAXIMUM RATINGS are exceeded. Functional operation should be restricted to RECOMMENDED OPERATING CONDITIONS. Exposure to higher than recommended voltages for extended periods of time could affect device reliability.
2. This is a steady–state DC parameter that is in effect after the power supply has achieved its nominal operating level. Power sequencing is not necessary.
3. Power dissipation capability is dependent upon package characteristics and use environment. See Package Thermal Characteristics.

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high–impedance circuit.

NOTES:
1. Write is defined as either any $\overline{SBx}$ and $\overline{SW}$ low or $\overline{SGW}$ is low. Chip Enable is defined as $\overline{SE1}$ low, SE2 high, and $\overline{SE3}$ low whenever $\overline{ADSP}$ or ADSC is asserted.
2. All read and write cycle timings are referenced from K or $\overline{G}$.
3. In order to reduce test correlation issues and to reduce the effects of application specific input edge rate variations on correlation between data sheet parameters and actual system performance, FSRAM AC parametric specifications are always specified at $V_{DDQ}/2$. In some design exercises, it is desirable to evaluate timing using other reference levels. Since the maximum test input edge rate is known and is given in the AC Test Conditions section of the data sheet as 1 V/ns, one can easily interpolate timing values to other reference levels.
4. This parameter is sampled and not 100% tested.
5. Measured at ± 200 mV from steady state.

1. Input waveform has a slew rate of 1 V/ns.
2. Rise time is measured from 0.5 to 2.0 V unloaded.
3. Fall time is measured from 2.0 to 0.5 V unloaded.

APPLICATION INFORMATION

STOP CLOCK OPERATION

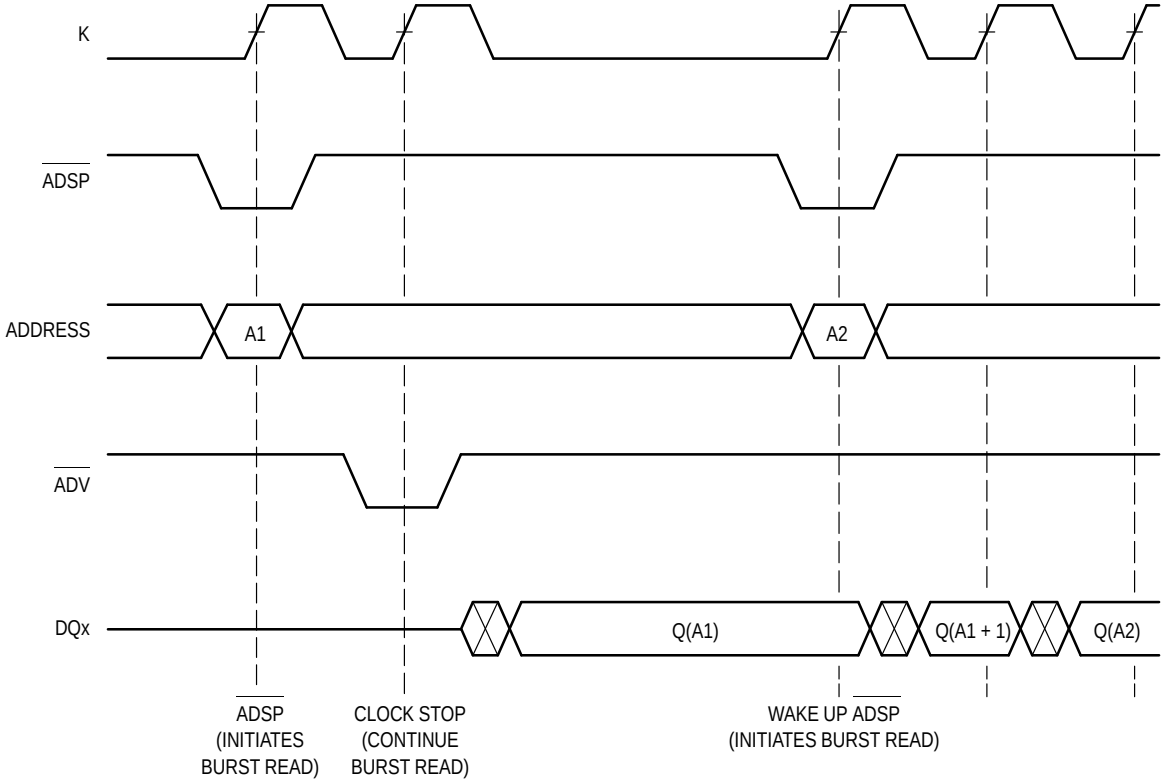
In the stop clock mode of operation, the SRAM will hold all state and data values even though the clock is not running (full static operation). The SRAM design allows the clock to start with ADSP and ADSC, and stops the clock after the last write data is latched, or the last read data is driven out.

When starting and stopping the clock, the AC clock timing and parametrics must be strictly maintained. For example, clock pulse width and edge rates must be guaranteed when starting and stopping the clocks.

To achieve the lowest power operation for all three stop clock modes, stop read, stop write, and stop deselect:

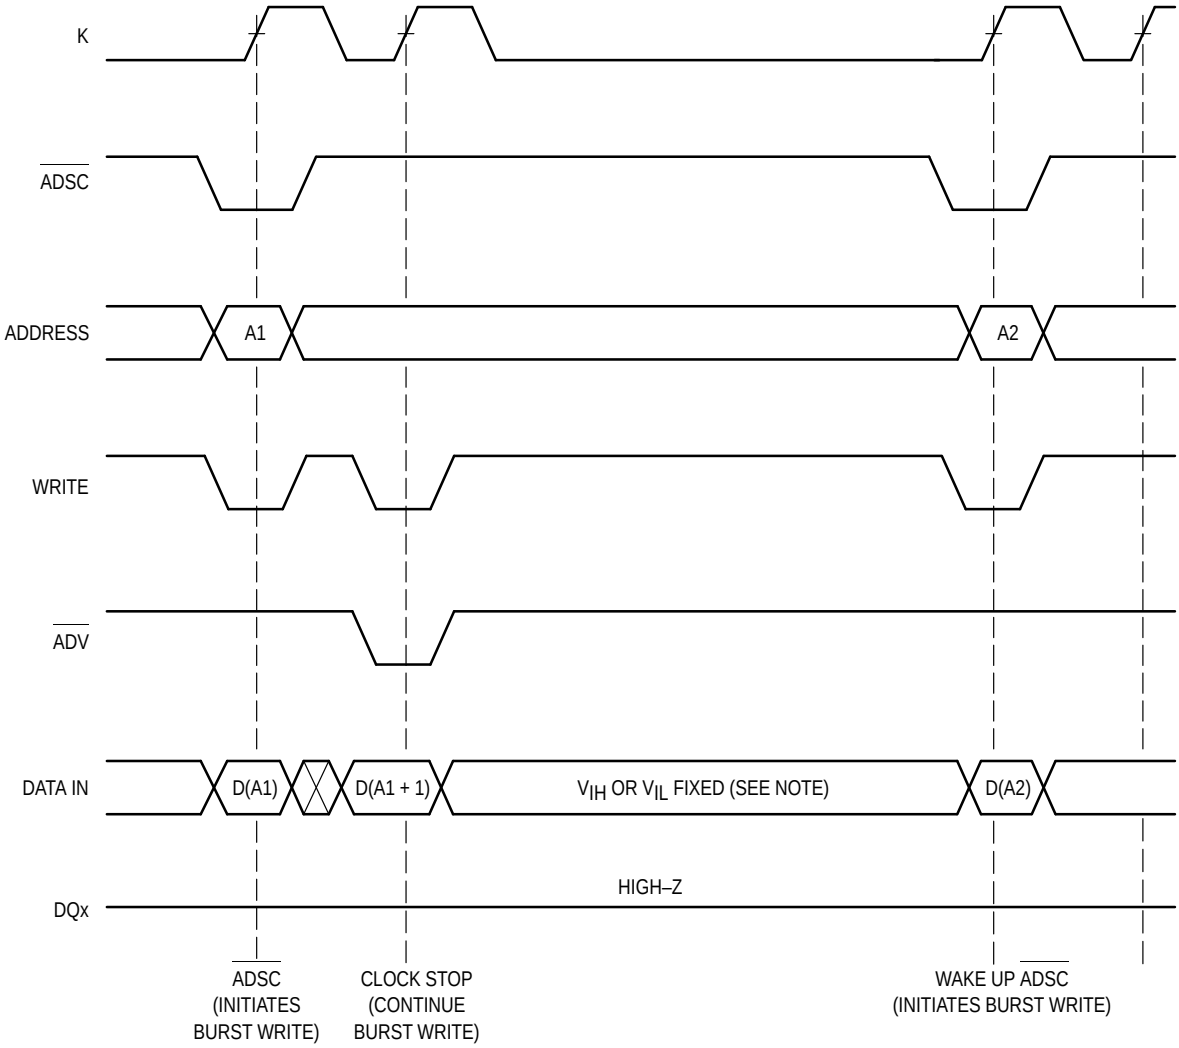
- Force the clock to a low state.
- Force the control signals to an inactive state (this guarantees any potential source of noise on the clock input will not start an unplanned on activity).
- Force the address inputs to a low state.

STOP CLOCK WITH READ TIMING



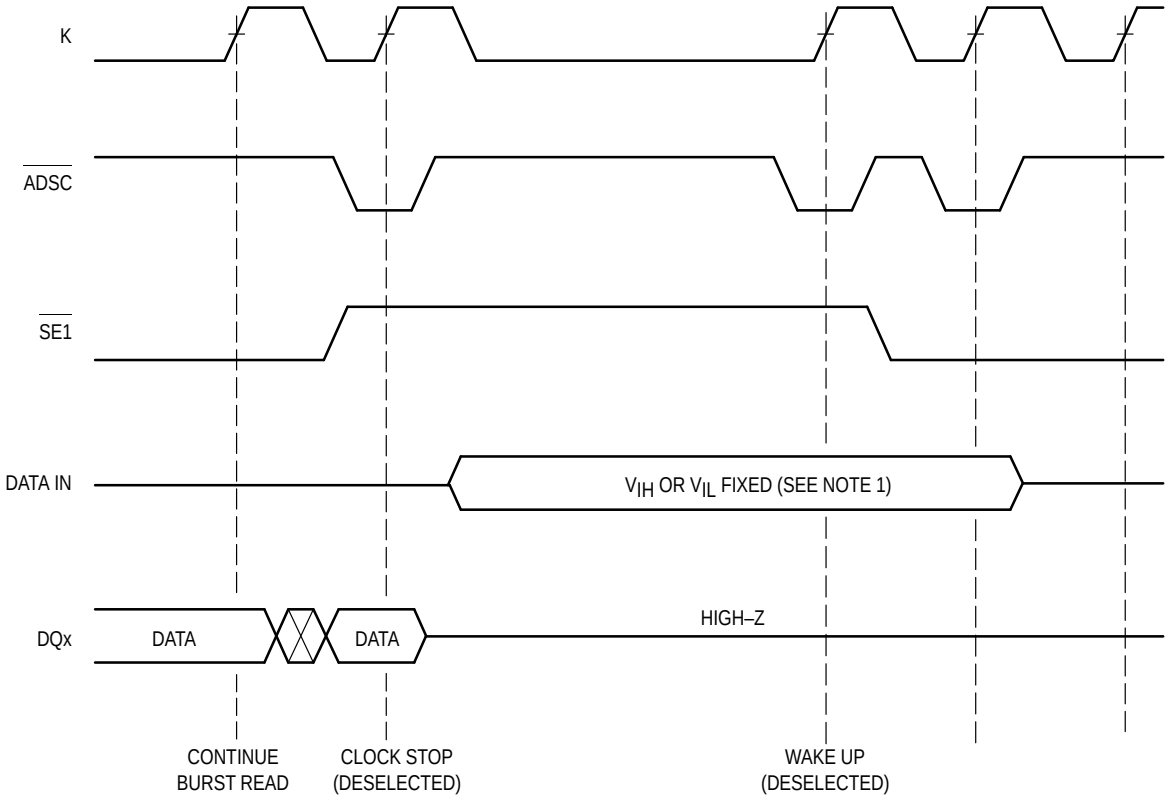
NOTE: For lowest possible power consumption during stop clock, the addresses should be driven to a low state (V_{IL}). Best results are obtained if V_{IL} < 0.2 V.

STOP CLOCK WITH WRITE TIMING



NOTE: While the clock is stopped, DATA IN must be fixed in a high (V_{IH}) or low (V_{IL}) state to reduce the DC current of the input buffers. For lowest power operation, all data and address lines should be held in a low (V_{IL}) state and control lines held in an inactive state.

STOP CLOCK WITH DESELECT OPERATION TIMING



NOTES:

1. While the clock is stopped, DATA IN must be fixed in a high (V_{IH}) or low (V_{IL}) state to reduce the DC current of the input buffers. For lowest power operation, all data and address lines should be held in a low (V_{IL}) state and control lines held in an inactive state.
2. For best possible power savings, the data–in should be driven low.

NON–BURST SYNCHRONOUS OPERATION

Although this BurstRAM has been designed for PowerPC–based and other high end MPU–based systems, these SRAMs can be used in other high speed L2 cache or memory applications that do not require the burst address feature. Most L2 caches designed with a synchronous interface can make use of the MCM69P819. The burst counter feature of the BurstRAM can be disabled, and the SRAM can be configured to act upon a continuous stream of addresses. See Figure 6.

CONTROL PIN TIE VALUES EXAMPLE ($H \geq V_{IH}$, $L \leq V_{IL}$)

Non–Burst	ADSP	ADSC	ADV	SE1	SE2	LBO
Sync Non–Burst, Pipelined SRAM	H	L	H	L	H	X

NOTE: Although X is specified in the table as a don't care, the pin must be tied either high or low.
