

114 dB, 192 kHz, Multi-Bit Audio A/D Converter

Features

- Advanced Multi-bit Delta-Sigma Architecture
- 24-Bit Conversion
- 114 dB Dynamic Range
- -105 dB THD+N
- System Sampling Rates up to 192 kHz
- Less than 150 mW Power Consumption
- High Pass Filter or DC Offset Calibration
- Supports Logic Levels Between 5 and 2.5V
- Differential Analog Architecture
- Linear Phase Digital Anti-Alias Filtering
- Overflow Detection

General Description

The CS5361 is a complete analog-to-digital converter for digital audio systems. It performs sampling, analog-to-digital conversion and anti-alias filtering, generating 24-bit values for both left and right inputs in serial form at sample rates up to 192 kHz per channel.

The CS5361 uses a 5th-order, multi-bit delta-sigma modulator followed by digital filtering and decimation, which removes the need for an external anti-alias filter. The ADC uses a differential architecture which provides excellent noise rejection.

The CS5361 is ideal for audio systems requiring wide dynamic range, negligible distortion and low noise, such as A/V receivers, DVD-R, CD-R, digital mixing consoles, and effects processors.

ORDERING INFORMATION

CS5361-KS	-10° to 70° C	24-pin SOIC
CS5361-BS	-40° to 85° C	24-pin SOIC
CS5361-KZ	-10° to 70° C	24-pin TSSOP
CS5361-BZ	-40° to 85° C	24-pin TSSOP
CDB5361		Evaluation Board

1 PIN DESCRIPTIONS

Pin Name	#	Pin Description
$\overline{\text{RST}}$	1	Reset (Input) - The device enters a low power mode when low.
$\overline{\text{M/S}}$	2	Master/Slave Mode (Input) - Selects operation as either clock master or slave.
LRCK	3	Left Right Clock (Input/Output) - Determines which channel, Left or Right, is currently active on the serial audio data line.
SCLK	4	Serial Clock (Input/Output) - Serial clock for the serial audio interface.
MCLK	5	Master Clock (Input) - Clock source for the delta-sigma modulator and digital filters.
VD	6	Digital Power (Input) - Positive power supply for the digital section.
GND	7, 18	Ground (Input) - Ground reference. Must be connected to analog ground.
VL	8	Logic Power (Input) - Positive power for the digital input/output.
SDOUT	9	Serial Audio Data Output (Output) - Output for two's complement serial audio data.
MDIV	10	MCLK Divider (Input) - Enables a master clock divide by two function.
HPF	11	High Pass Filter Enable (Input) - Enables the Digital High-Pass Filter.
I ² S/LJ	12	Serial Audio Interface Format Select (Input) - Selects either the left-justified or I ² S format for the SAI.
M0	13,	Mode Selection (Input) - Determines the operational mode of the device.
M1	14	
$\overline{\text{OVFL}}$	15	Overflow (Output, open drain) - Detects an overflow condition on both left and right channels.
AINL+	16,	Differential Left Channel Analog Input (Input) - Signals are presented differentially to the delta-sigma modulators via the AINL+/- pins.
AINL-	17	
VA	19	Analog Power (Input) - Positive power supply for the analog section.
AINR-	20,	Differential Right Channel Analog Input (Input) - Signals are presented differentially to the delta-sigma modulators via the AINR+/- pins.
AINR+	21	
VQ	22	Quiescent Voltage (Output) - Filter connection for the internal quiescent reference voltage.
REF_GND	23	Reference Ground (Input) - Ground reference for the internal sampling circuits.
FILT+	24	Positive Voltage Reference (Output) - Positive reference voltage for the internal sampling circuits.

2 TYPICAL CONNECTION DIAGRAM

Figure 1. Typical Connection Diagram

3 APPLICATIONS

3.1 Operational Mode/Sample Rate Range Select

The output sample rate, F_s , can be adjusted from 2kHz to 192kHz. The CS5361 must be set to the proper speed mode via the mode pins, M1 and M0. Refer to Table 1.

M1 (Pin 14)	M0 (Pin 13)	MODE	Output Sample Rate (F_s)
0	0	Single Speed Mode	2kHz - 50kHz
0	1	Double Speed Mode	50kHz - 100kHz
1	0	Quad Speed Mode	100kHz - 192kHz
1	1	Reserved	

Table 1. CS5361 Mode Control

3.2 System Clocking

The device supports operation in either Master Mode, where the left/right and serial clocks are synchronously generated on-chip, or Slave Mode, which requires external generation of the left/right and serial clocks. The device also includes a master clock divider in Master Mode where the master clock will be internally divided prior to any other internal circuitry when MDIV is enabled, set to logic 1. In Slave Mode, the MDIV pin needs to be disabled, set to logic 0.

3.2.1 Master Mode

In Master mode, LRCK and SCLK operate as outputs. The left/right and serial clocks are internally derived from the master clock with the left/right clock equal to F_s and the serial clock equal to $64 \times F_s$, as shown in Figure 2. Refer to Table 2 for common master clock frequencies.

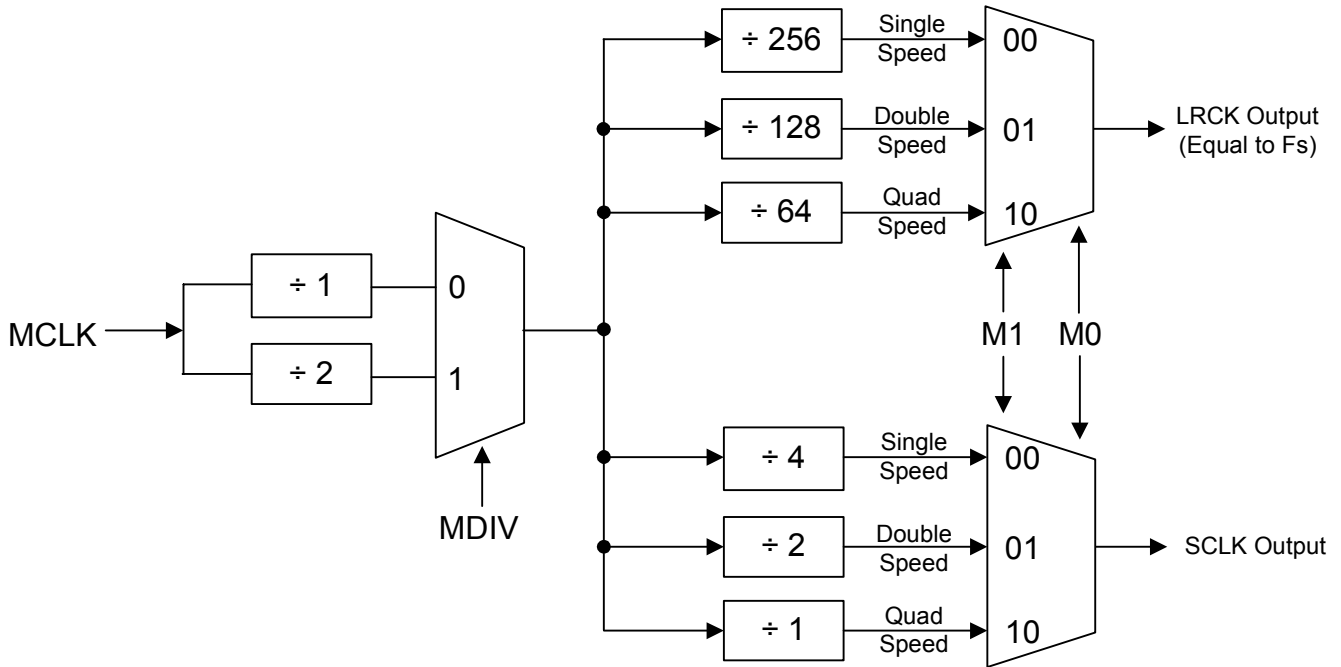

Figure 2. CS5361 Master Mode Clocking

SAMPLE RATE (kHz)	MDIV = 0 MCLK (MHz)	MDIV = 1 MCLK (MHz)
32	8.192	16.384
44.1	11.2896	22.5792
48	12.288	24.576
64	8.192	16.384
88.2	11.2896	22.5792
96	12.288	24.576
176.4	11.2896	22.5792
192	12.288	24.576

Table 2. CS5361 Common Master Clock Frequencies

3.2.2 Slave Mode

LRCK and SCLK operate as inputs in Slave mode. The left/right clock must be synchronously derived from the master clock and be equal to F_s . It is also recommended that the serial clock be synchronously derived from the master clock and be equal to $64 \times F_s$ to maximize system performance. Refer to Table 3 for required clock ratios.

	Single Speed Mode $F_s = 2\text{kHz to } 50\text{kHz}$	Double Speed Mode $F_s = 50\text{kHz to } 100\text{kHz}$	Quad Speed Mode $F_s = 100\text{kHz to } 192\text{kHz}$
MCLK/LRCK Ratio	256x, 512x	128x, 256x	128x, 256x
SCLK/LRCK Ratio	32x, 64x, 128x	32x, 64x	64x

Table 3. CS5361 Slave Mode Clock Ratios

3.3 Power-up Sequence

Reliable power-up can be accomplished by keeping the device in reset until the power supplies, clocks and configuration pins are stable. It is also recommended that reset be enabled if the analog or digital supplies drop below the minimum specified operating voltages to prevent power glitch related issues.

The internal reference voltage must be stable for the device to produce valid data. Therefore, there is a delay between the release of reset and the generation of valid output, due to the finite output impedance of FILT+ and the presence of the external capacitance.

3.4 Analog Connections

The analog modulator samples the input at 6.144 MHz (MCLK=12.288 MHz). The digital filter will reject signals within the stopband of the filter. However, there is no rejection for input signals which are $(n \times 6.144 \text{ MHz})$ the digital passband frequency, where $n=0,1,2,\dots$ Refer to Figure 3 which shows the suggested filter that will attenuate any noise energy at 6.144 MHz, in addition to providing the optimum source impedance for the modulators. The use of capacitors which have a large voltage coefficient (such as general purpose ceramics) must be avoided since these can degrade signal linearity.

Please see the Addendum at the end of the datasheet for an analog input buffer that can be used with both the CS5351 as well as the CS5361 with a simple change in the bill of materials.

Figure 3. CS5361 Recommended Analog Input Buffer

3.5 High Pass Filter and DC Offset Calibration

The operational amplifiers in the input circuitry driving the CS5361 may generate a small DC offset into the A/D converter. The CS5361 includes a high pass filter after the decimator to remove any DC offset which could result in recording a DC level, possibly yielding "clicks" when switching between devices in a multichannel system.

The high pass filter continuously subtracts a measure of the DC offset from the output of the decimation filter. If the $\overline{\text{HPF}}$ pin is taken high during normal operation, the current value of the DC offset register is frozen and this DC offset will continue to be subtracted from the conversion result. This feature makes it possible to perform a system DC offset calibration by:

- 1) Running the CS5361 with the high pass filter enabled until the filter settles. See the Digital Filter Characteristics for filter settling time.
- 2) Disabling the high pass filter and freezing the stored DC offset.

A system calibration performed in this way will eliminate offsets anywhere in the signal path between the calibration point and the CS5361.

3.6 Overflow Detection

The CS5361 includes overflow detection on both the left and right channels. This time multiplexed information is presented as open drain, active low on pin 15, $\overline{\text{OVFL}}$. The $\overline{\text{OVFL}}_L$ and $\overline{\text{OVFL}}_R$ data will go to a logical low as soon as an overrange condition in either channel is detected. The data will remain low

as specified in the Switching Characteristics - Serial Audio Port section. This ensures sufficient time to detect an overrange condition regardless of the speed mode. After the timeout, the OVFL_L and OVFL_R data will return to a logical high if there has not been any other overrange condition detected. Please note that an overrange condition on either channel will restart the timeout period for both channels.

3.6.1 $\overline{\text{OVFL}}$ Output Timing

In left-justified format, the $\overline{\text{OVFL}}$ pin is updated one SCLK period after an LRCK transition. In I²S format, the $\overline{\text{OVFL}}$ pin is updated two SCLK periods after an LRCK transition. Refer to Figures 23 and 24. In both cases the $\overline{\text{OVFL}}$ data can be easily demultiplexed by using the LRCK to latch the data. In left-justified format, the rising edge of LRCK would latch the right channel overflow status, and the falling edge of LRCK would latch the left channel overflow status. In I²S format, the falling edge of LRCK would latch the right channel overflow status and the rising edge of LRCK would latch the left channel overflow status.

3.7 Grounding and Power Supply Decoupling

As with any high resolution converter, the CS5361 requires careful attention to power supply and grounding arrangements if its potential performance is to be realized. Figure 1 shows the recommended power arrangements, with VA and VL connected to clean supplies. VD, which powers the digital filter, may be run from the system logic supply or may be powered from the analog supply via a resistor. In this case, no additional devices should be powered from VD. Decoupling capacitors should be as near to the ADC as possible, with the low value ceramic capacitor being the nearest. All signals, especially clocks, should be kept away from the FILT+ and VQ pins in order to avoid unwanted coupling into the modulators. The FILT+ and VQ decoupling capacitors, particularly the 0.1 μF , must be positioned to minimize the electrical path from FILT+ and REFGND. The CDB5361 evaluation board demonstrates the optimum layout and power supply arrangements. To minimize digital noise, connect the ADC digital outputs only to CMOS inputs.

3.8 Synchronization of Multiple Devices

In systems where multiple ADCs are required, care must be taken to achieve simultaneous sampling. To ensure synchronous sampling, the MCLK and LRCK must be the same for all of the CS5361's in the system. If only one master clock source is needed, one solution is to place one CS5361 in Master mode, and slave all of the other CS5361's to the one master. If multiple master clock sources are needed, a possible solution would be to supply all clocks from the same external source and time the CS5361 reset with the inactive edge of MCLK. This will ensure that all converters begin sampling on the same clock edge.

4 CHARACTERISTICS AND SPECIFICATIONS

ANALOG CHARACTERISTICS (CS5361-KS/KZ) (Test conditions (unless otherwise specified): Input test signal is a 1 kHz sine wave; measurement bandwidth is 10 Hz to 20 kHz. Typical performance characteristics are derived from measurements taken at $T_A = 25^\circ\text{C}$, $V_L = V_D = 3.3\text{V}$ and $V_A = 5.0\text{V}$. Min/Max performance characteristics are guaranteed over the specified operating temperature and voltages.)

Parameter	Symbol	Min	Typ	Max	Unit
Single Speed Mode $F_s = 48\text{kHz}$					
Dynamic Range	A-weighted	108	114	-	dB
	unweighted	105	111	-	dB
Total Harmonic Distortion + Noise (Note 1)	-1 dB	-	-105	-99	dB
	-20 dB	-	-91	-	dB
	-60 dB	-	-51	-	dB
Double Speed Mode $F_s = 96\text{kHz}$					
Dynamic Range	A-weighted	108	114	-	dB
	unweighted	105	111	-	dB
	40kHz bandwidth unweighted	-	108	-	dB

Analog Input Voltage	(Note 9)	V_{IN}	GND-0.7	-	VA+0.7	V
Digital Input Voltage	(Note 9)	V_{IND}	-0.7	-	VL+0.7	V
Ambient Operating Temperature (Power Applied)		T_A	-50	-	+95	°C
Storage Temperature		T_{stg}	-65	-	+150	°C

- Notes:
7. Any pin except supplies. Transient currents of up to ±100 mA on the analog input pins will not cause SRC latch-up.
 8. The maximum over/under voltage is limited by the input current.
 9. Operation beyond these limits may result in permanent damage to the device. Normal operation is not guaranteed at these extremes.

SWITCHING CHARACTERISTICS - SERIAL AUDIO PORT (Logic "0" = GND = 0 V;
Logic "1" = VL = 1.7V to 5.25V, VA = 5V±5%, VD = 3.1V to 5.25V, CL = 20 pF)

Parameter	Symbol	Min	Typ	Max	Unit	
Input Sample Rate	Single Speed Mode	Fs	2	-	50	kHz
	Double Speed Mode	Fs	50	-	100	kHz
	Quad Speed Mode	Fs	100	-	192	kHz

5 PARAMETER DEFINITIONS

Dynamic Range

The ratio of the rms value of the signal to the rms sum of all other spectral components over the specified bandwidth. Dynamic Range is a signal-to-noise ratio measurement over the specified bandwidth made with a -60 dBFS signal. 60 dB is added to resulting measurement to refer the measurement to full-scale. This technique ensures that the distortion components are below the noise level and do not affect the measurement. This measurement technique has been accepted by the Audio Engineering Society, AES17-1991, and the Electronic Industries Association of Japan, EIAJ CP-307. Expressed in decibels.

Total Harmonic Distortion + Noise

The ratio of the rms value of the signal to the rms sum of all other spectral components over the specified bandwidth (typically 10 Hz to 20 kHz), including distortion components. Expressed in decibels. Measured at -1 and -20 dBFS as suggested in AES17-1991 Annex A.

Frequency Response

A measure of the amplitude response variation from 10 Hz to 20 kHz relative to the amplitude response at 1 kHz. Units in decibels.

Interchannel Isolation

A measure of crosstalk between the left and right channels. Measured for each channel at the converter's output with no signal to the input under test and a full-scale signal applied to the other channel. Units in decibels.

Interchannel Gain Mismatch

The gain difference between left and right channels. Units in decibels.

Gain Error

The deviation from the nominal full-scale analog output for a full-scale digital input.

Gain Drift

The change in gain value with temperature. Units in ppm/°C.

Offset Error

The deviation of the mid-scale transition (111...111 to 000...000) from the ideal. Units in mV.

JEDEC #: MO-153

Controlling Dimension is Millimeters.

- Notes:
1. "D" and "E1" are reference datums and do not include mold flash or protrusions, but do include mold mismatch and are measured at the parting line, mold flash or protrusions shall not exceed 0.20 mm per side.
 2. Dimension "b" does not include dambar protrusion/intrusion. Allowable dambar protrusion shall be 0.13 mm total in excess of "b" dimension at maximum material condition. Dambar intrusion shall not reduce dimension "b" by more than 0.07 mm at least material condition.
 3. These dimensions apply to the flat section of the lead between 0.10 and 0.25 mm from lead tips.

7 ADDENDUM

The CS5351 and CS5361 family of analog-to-digital converters are functionally compatible and can easily be interchanged with minimal modifications to the input buffer circuitry.

Figure 25 shows an analog input buffer that provides anti-alias filtering, proper dc biasing, and optimum source impedance for the modulators. The input buffer shown will work well with both the CS5351 and the CS5361, merely by changing the bill of materials.

In order to use this buffer design with the CS5351, one would stuff the 0ohm resistors R19 and R22 and not populate R3 and R20. This will create a single-ended input buffer with the unused differential input pin connected to the quiescent voltage of the converter (VQ). Note that in this configuration, it is unnecessary to have the second op-amp and related components.

In order to use this buffer design with the CS5361, one would stuff the 0ohm resistors R3 and R20 and not populate R19 and R22. This will create a fully differential analog input buffer (as shown in Figure 3).
