System Reset (Built-in Watch Dog Timer) Monolithic IC MM1099

Outline

The function of this IC series MM1099 is to accurately reset systems, a generating reset signal at the time of instantaneous supply voltage off or lowering in varied CPU and other logic system.

Further, with the watch dog timer built-in it can diagnose the operation of the system, intermittently generating reset pulses when they operate erroneously to prevent runaway.

Features

- 1. Built-in watch dog timer
- 2. Low current consumption 130µA TYP.
- 3. Low operating threshold voltage Vcc=0.8V
- 4. Watch dog stop function (RCT terminal)
- 5. Long clock monitoring time
 - TPR (POWER ON): Two (clock monitoring)=1:1
- 6. Fewer outer components

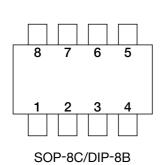

Package

DIP-8B (MM1099AD, MM1099BD) SOP-8C (MM1099AF, MM1099BF) SIP-8A (MM1099AS, MM1099BS)

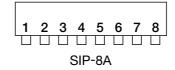

Applications

- 1. Reset circuit for microcomputers, CPU and MPU.
- 2. Reset circuit for logic circuitry.
- 3. Monitoring of microcomputer system, etc.

Pin Description

Pin No.	Pin name	Function						
1	тс	Variable terminals Twd, Twr and Tpr TPR (mS) = $5000 \times CT$ (μF) The time for Twd, Twr and Tpr to be TWD (mS) = $500 \times CT$ (μF) determined by the external capacitor. TWR (mS) = $100 \times CT$ (μF)						
2	N.C							
3	CK	Clock input terminal Inputs the clock from the logic system.						
4	GND	Ground terminal						
5	Vcc	Voltage detection MM1099A→3.2V MM1099B→4.2V						
6	RCT	Watchdog timer stop pin Operation modes: Operation → OPEN, Stop → connect to GND						
7	Vs	Detect voltage variable terminal						
8	RESET	Reset output pin (low output)

Notes:

- *1 The "monitoring time" means the time interval from the last pulse of the clock pulses for timer clear (negative edge) to the output of the reset pulse. If the clock pulse is not input during this time interval, the reset output will be given.
- *2 The "reset time" is no other than the reset pulse width, except when resetting the POWER ON.
- *3 The "reset hold time" is the time interval from the time point when Vcc exceeds the detect (Vsh) at the time of Power On Reset (Power variation reset) to the reset release (RESET output "HIGH").
- *4 The "output delay time" means the time interval from when the supply voltage comes lower than the detect voltage (VsL) to when comes the reset state (RESET output "Low").
- *5 The voltage range is 10 to 90% when measuring the output rise and fall times.
- *6 By varying the capacitance of C_T, we can vary the watch dog timer monitoring time (TwD), the reset time at the time of the watch dog timer (TwR), and the reset hold time at the time of power source rise (TPR). The variable time can be expressed by the following formulas:

TPR (mS) = 5000 \times CT (μ F)

Two (mS) = 5000 \times CT (μ F)

Twr (mS) = 100 \times CT (μ F)

Example: When CT=0.02µF

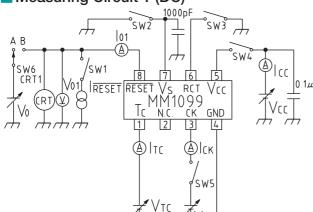

TPR ≒ 100mS

Two ≒ 100mS

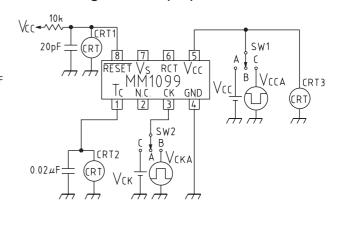

Twr ≒ 2mS

Block Diagram

	RA	Rв
MM1099A	≃ 305k	≃ 195k
MM1099B	≃350k	≃ 150k

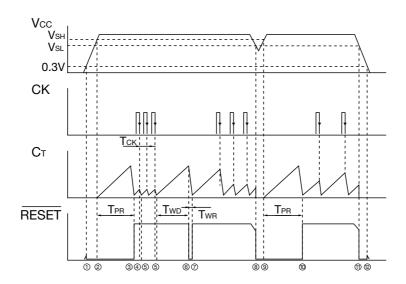

Note 1. Cp = approx. $0.1\mu F$

Note 2. $C \simeq 1000 pF$

Note 3. The watchdog timer can be stopped by grounding the RCT pin. (Function as voltage detection circuit.)

Note 4. TPR, Two can be varied by pulling up the RCT pit to Vcc using a resisteor.

Timing Chart

Description of Operation

- 1. The RESET will become "Low" if Vcc rises to about 0.8V.

 Approximately 1µA (Vcc=0.8V) of pull up current is output from RESET
- 2. Charging starts at the capacitor C_T when V_{CC} riset to V_{SH} (MM1099A ≒ 3.25V, MM1099B ≒ 4.3V), when the output has been reset.
- 3. The output reset is released after a given interval TPR from when the CT Starts charging and to when it discharges (that is, the time from when CT voltage takes a given value 1 (≒ 1.4V) up until decreases to a given value 2 (≒ 0.2V). (RESET will become "High"). The RESET will output a pull up current, about 1µA (Vcc=0.8V). The reset hold time TPR is expressed by the following formula:

TPR (ms) $= 5000 \times CT (\mu F)$

After the reset release C_T restarts charging and the watch dog timer begins operating.

Note that input of clock while POWER ON RESET time TPR will cause an erroneous operation.

- 4. If clock is input into CK terminal while C_T is charging (negative edge trigger), C_T changes from charging over to discharging.
- 5. When the C_T voltage decreases to a given threshold (≒ 0.2V), then discharging changes over to charging. Steps 4 and 5 will be repeated while normal clock is input from the logic system.
- 6. When the clock ceases and C_T voltage reaches the RESET ON threshold (≒ 1.4V), the output enters into reset state (RESET becoming "Low").

The C_T charging time T_{WD} up until the reset is output (watch dog monitoring time) is expressed by the following formula:

Two (ms) $= 5000 \times C_T (\mu F)$

7. The reset time at the time of watch dog time TwR is the discharging time while the C_T voltage lowers down to the reset off threshold (≒ 0.2V). The calculation formula:

Twr (ms) $= 100 \times C_T (\mu F)$

After the reset off threshold is reached, the output reset is released and C_T commences to charge. If thenceforth the clock is input normally, steps 4 and 5 will be repeated, and setps 6 and 7 repeated if the clock ceases.

- 8. When Vcc lowers down to VsL (MM1099A ≒ 3.2V, MM1099B ≒ 4.2V), the reset is output. At the same time C⊤ charged.
- 9. C_T discharging starts when V_{CC} rises up to V_{SH} .
 - If Vcc lower instantaneously, charging starts after load discharging of C_T if the time interval from when Vcc comes lower than VsL up until when it rises to VsH or higher is equal or superior to the reference value of Vcc input pulse width Tpl.
- 10. The output reset is released TpR after Vcc becomes VsH or higher, and the watch dog time will start. Then if Vcc becomes VsL or lower, steps 8 to 10 will be repeated.
- 11. If power Off occurs, reset is output if Vcc becomes VsL or lower.
- 12. When Vcc comes down to 0V, the reset output will hold up until Vcc becomes 0.8V.
