

# Micropower Dual 10-Bit DAC in MSOP

January 1999

## FEATURES

- **Tiny: Two 10-Bit DACs in an 8-Lead MSOP—  
Half the Board Space of an SO-8**
- **Ultralow Power: 60 $\mu$ A per DAC Plus 1 $\mu$ A Sleep  
Mode for Extended Battery Life**
- Wide 2.7V to 5.5V Supply Range
- Double Buffered for Independent or Simultaneous  
DAC Updates
- **Rail-to-Rail Voltage Outputs Drive 1000pF**
- Reference Range Includes Supply for Ratiometric  
0V-to- $V_{CC}$  Output
- 3-Wire Serial Interface with  
Schmitt Trigger Inputs
- Differential Nonlinearity:  $\leq \pm 0.75\text{LSB}$  Max

## APPLICATIONS

- Mobile Communications
- Digitally Controlled Amplifiers and Attenuators
- Portable Battery-Powered Instruments
- Automatic Calibration for Manufacturing
- Remote Industrial Devices

## DESCRIPTION

The LTC<sup>®</sup>1661 integrates two accurate, addressable, 10-bit digital-to-analog converters (DACs) in a single tiny MS8 package. Each buffered DAC consumes just 60 $\mu$ A total supply current, yet is capable of supplying DC output currents in excess of 5mA and reliably driving capacitive loads up to 1000pF. Sleep mode further reduces total supply current to a negligible 1 $\mu$ A.

Linear Technology's proprietary, inherently monotonic voltage interpolation architecture provides excellent linearity while allowing for an exceptionally small external form factor. The double-buffered input logic provides simultaneous update capability and can be used to write to either DAC without interrupting Sleep mode.

Ultralow supply current, power-saving Sleep mode and extremely compact size make the LTC1661 ideal for battery-powered applications, while its straightforward usability, high performance and wide supply range make it an excellent choice as a general purpose converter.

For additional outputs and even greater board density, please refer to the LTC1660 micropower octal 10-bit DAC.

The ● denotes specifications which apply over the full operating temperature range.

**Note 1:** Absolute maximum ratings are those values beyond which the life of a device may be impaired.

**Note 2:** Nonlinearity and monotonicity are defined from the first code that is greater than or equal to the maximum offset specification to code 1023 (full scale). See Applications Information.

**Note 3:** Digital inputs at 0V or  $V_{CC}$ .

**Note 4:** Load is  $10k\Omega$  in parallel with  $100pF$ .

**Note 5:**  $V_{CC} = V_{REF} = 5V$ . DAC switched between  $0.1V_{FS}$  and  $0.9V_{FS}$ , i.e., codes  $k = 102$  and  $k = 922$ .

**Note 6:** Guaranteed by design and not subject to test.

## TIMING DIAGRAM

## PIN FUNCTIONS

**CS/LD (Pin 1):** Serial Interface Chip Select/Load Input. When CS/LD is low, CLK is enabled for shifting data on D<sub>IN</sub> into the register. When CS/LD is pulled high, CLK is disabled and data is loaded from the shift register into the specified DAC register(s), updating the analog output(s). CMOS and TTL compatible.

**CLK (Pin 2):** Serial Interface Clock Input. CMOS and TTL compatible.

**D<sub>IN</sub> (Pin 3):** Serial Interface Data Input. Data on the D<sub>IN</sub> pin is shifted into the 16-bit register on the rising edge of CLK. CMOS and TTL compatible.

**REF (Pin 4):** Reference Voltage Input.  $0V \leq V_{REF} \leq V_{CC}$ .

**V<sub>OUT A</sub>, V<sub>OUT B</sub> (Pins 8,5):** DAC Analog Voltage Outputs. The output range is

$$0 \text{ to } V_{REF} \left( \frac{1023}{1024} \right)$$

**V<sub>CC</sub> (Pin 6):** Supply Voltage Input.  $2.7V \leq V_{CC} \leq 5.5V$ .

**GND (Pin 7):** System Ground.

## DEFINITIONS

**Differential Nonlinearity (DNL):** The difference between the measured change and the ideal 1LSB change for any two adjacent codes. The DNL error between any two codes is calculated as follows:

$$DNL = (\Delta V_{OUT} - LSB) / LSB$$

Where  $\Delta V_{OUT}$  is the measured voltage difference between two adjacent codes.

**Digital Feedthrough:** The glitch that appears at the analog output caused by AC coupling from the digital inputs when they change state. The area of the glitch is specified in (nV)(sec).

**Full-Scale Error (FSE):** The deviation of the actual full-scale voltage from ideal. FSE includes the effects of offset and gain errors (see Applications Information).

**Integral Nonlinearity (INL):** The deviation from a straight line passing through the endpoints of the DAC transfer curve (Endpoint INL). Because the output cannot go below zero, the linearity is measured between full scale and the lowest code which guarantees the output will be greater than zero. The INL error at a given input code is calculated as follows:

$$INL = [V_{OUT} - V_{OS} - (V_{FS} - V_{OS})(code/1023)] / LSB$$

Where  $V_{OUT}$  is the output voltage of the DAC measured at the given input code.

## DEFINITIONS

**Least Significant Bit (LSB):** The ideal voltage difference between two successive codes.

$$\text{LSB} = V_{\text{REF}}/1024$$

**Resolution (n):** Defines the number of DAC output states ( $2^n$ ) that divide the full-scale range. Resolution does not imply linearity.

**Voltage Offset Error ( $V_{\text{OS}}$ ):** Nominally, the voltage at the output when the DAC is loaded with all zeros. A single supply DAC can have a true negative offset, but the output cannot go below zero (see Applications Information).

For this reason, single supply DAC offset is measured at the lowest code that guarantees the output will be greater than zero.

## OPERATION

### Transfer Function

The transfer function for the LTC1661 is:

$$V_{\text{OUT(IDEAL)}} = \left( \frac{k}{1024} \right) V_{\text{REF}}$$

where  $k$  is the decimal equivalent of the binary DAC input code D9-D0 and  $V_{\text{REF}}$  is the voltage at REF (Pin 6).

### Power-On Reset

The LTC1661 positively clears the outputs to zero scale when power is first applied, making system initialization consistent and repeatable.

### Power Supply Sequencing

The voltage at REF (Pin 4) must not ever exceed the voltage at  $V_{\text{CC}}$  (Pin 6) by more than 0.2V. Particular care should be taken in the power supply turn-on and turn-off sequences to assure that this limit is observed. See Absolute Maximum Ratings.

### Serial Interface

See Table 1. The 16-bit input word consists of the 4-bit DAC control code, the 10-bit input code and two don't care bits.

**Table 1. LTC1661 Input Word**

|         |    |    |    |            |    |    |    |    |    |    |    |    |    |            |    |
|---------|----|----|----|------------|----|----|----|----|----|----|----|----|----|------------|----|
| A3      | A2 | A1 | A0 | D9         | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 | X1         | X0 |
| Control |    |    |    | Input Code |    |    |    |    |    |    |    |    |    | Don't Care |    |

The data path for the 10-bit input code is buffered by two latch registers. The first of these, the Input Register, is used for loading new input codes. The second buffer, the DAC

Register, is used for updating the DAC outputs. Each DAC has its own 10-bit Input Register and 10-bit DAC Register.

By selecting the appropriate 4-bit DAC control code (see Table 2) it is possible to perform single operations, such as loading one DAC or changing Power-Down status (Sleep/Wake). In addition, some control codes perform two or more operations at the same time. For example, one such code loads DAC A, updates both outputs and Wakes the part. The DACs can be loaded separately or together, but the outputs are always updated together.

### Register Loading Sequence

See Figure 1. With  $\overline{\text{CS/LD}}$  held low, data on the  $\text{D}_{\text{IN}}$  input is shifted into the 16-bit Shift Register on the positive edge of CLK. The 4-bit DAC control code, A3-A0, is loaded first, then the 10-bit input code, D9-D0, ordered MSB-to-LSB in each case. Two don't-care bits, X1 and X0, are loaded last. When the full 16-bit word has been shifted in,  $\overline{\text{CS/LD}}$  is pulled high, causing the system to respond according to Table 2. The clock is disabled internally when  $\overline{\text{CS/LD}}$  is high. Note: CLK must be low before  $\overline{\text{CS/LD}}$  is pulled low.

### Sleep Mode

DAC control code 1110<sub>b</sub> is reserved for the special Sleep instruction (see Table 2). In this mode, most internal bias currents are disabled while all digital circuitry stays fully active; static power consumption is thus virtually eliminated. The analog outputs are set in a high impedance state and all DAC settings are retained in memory so that when Sleep mode is exited, the outputs of DACs not updated by the Wake command are restored to their last active state.

## OPERATION

Table 2. DAC Control Functions

| CONTROL |    |    |    | INPUT REGISTER STATUS                | DAC REGISTER STATUS | POWER-DOWN STATUS (SLEEP/WAKE) | COMMENTS                                                                                                                       |

Figure 1. Register Loading Sequence

## OPERATION

Sleep mode is initiated by performing a load sequence using control code  $1110_b$  (the DAC input code D9-D0 is ignored). The input codes stored in the input register for each channel may be changed during Sleep by using control codes  $0001_b$  and  $0010_b$ .

### Voltage Outputs

Each of the rail-to-rail output amplifiers contained in the LTC1661 can typically source or sink up to 5mA ( $V_{CC} = 5V$ ). The outputs swing to within a few millivolts of either supply when unloaded and have an equivalent

output resistance of  $85\Omega$  (typical) when driving a load to the rails. The output amplifiers are stable driving capacitive loads up to 1000pF.

A small resistor placed in series with the output can be used to achieve stability for any load capacitance. For example, a  $0.1\mu F$  load can be successfully driven by inserting a  $110\Omega$  resistor. The phase margin of the resulting circuit is  $45^\circ$ , and increases monotonically from this point if larger values of resistance, capacitance or both are substituted for the values given.

## APPLICATIONS INFORMATION

### Rail-to-Rail Output Considerations

In any rail-to-rail DAC, the output swing is limited to voltages within the supply range.

If the DAC offset is negative, the output for the lowest codes limits at 0V as shown in Figure 2b.

Similarly, limiting can occur near full scale when the REF pin is tied to  $V_{CC}$ . If  $V_{REF} = V_{CC}$  and the DAC full-scale error (FSE) is positive, the output for the highest codes limits at

$V_{CC}$  as shown in Figure 2c. No full-scale limiting can occur if  $V_{REF}$  is less than  $V_{CC} - FSE$ .

Offset and linearity are defined and tested over the region of the DAC transfer function where no output limiting can occur.

Figure 2. Effects of Rail-to-Rail Operation On a DAC Transfer Curve. (a) Overall Transfer Function (b) Effect of Negative Offset for Codes Near Zero Scale (c) Effect of Positive Full-Scale Error for Input Codes Near Full Scale When  $V_{REF} = V_{CC}$

## PACKAGE DESCRIPTION

Dimensions in inches (millimeters) unless otherwise noted.

### MS8 Package 8-Lead Plastic MSOP (LTC DWG # 05-08-1660)

\* DIMENSION DOES NOT INCLUDE MOLD FLASH, PROTRUSIONS OR GATE BURRS. MOLD FLASH, PROTRUSIONS OR GATE BURRS SHALL NOT EXCEED  $0.006^*$  (0.152mm) PER SIDE

\*\* DIMENSION DOES NOT INCLUDE INTERLEAD FLASH OR PROTRUSIONS. INTERLEAD FLASH OR PROTRUSIONS SHALL NOT EXCEED  $0.006^*$  (0.152mm) PER SIDE

### N8 Package 8-Lead PDIP (Narrow 0.300) (LTC DWG # 05-08-1510)

\*THESE DIMENSIONS DO NOT INCLUDE MOLD FLASH OR PROTRUSIONS. MOLD FLASH OR PROTRUSIONS SHALL NOT EXCEED 0.010 INCH (0.254mm)
