High-Efficiency Step-Up Converters with Reverse Battery Protection in SOT23-6

MAX1832-MAX1835

General Description

The MAX1832–MAX1835 are high-efficiency step-up converters with complete reverse battery protection that protects the device and the load when the battery is reversed. They feature a built-in synchronous rectifier, which allows for over 90% efficiency and reduces size and cost by eliminating the need for an external Schottky diode.

These step-up converters operate from a +1.5V to +5.5V input voltage range and deliver up to 150mA of load current. The MAX1833/MAX1835 have a fixed +3.3V output, and the MAX1832/MAX1834 have adjustable outputs from +2V to +5.5V. In shutdown, the MAX1832/MAX1833 connect the battery input to the voltage output, allowing the input battery to be used as a backup or real-time clock supply when the converter is off (see *Selector Guide*).

The MAX1832–MAX1835 are available in a miniature 6-pin SOT23 package. The MAX1832EVKIT is available to shorten the design cycle.

Applications

- Medical Diagnostic Equipment
- Pagers
- Hand-Held Instruments
- Remote Wireless Transmitters
- Digital Cameras
- Cordless Phones
- Battery Backup
- PC Cards
- Local 3.3V or 5V Supply

Features

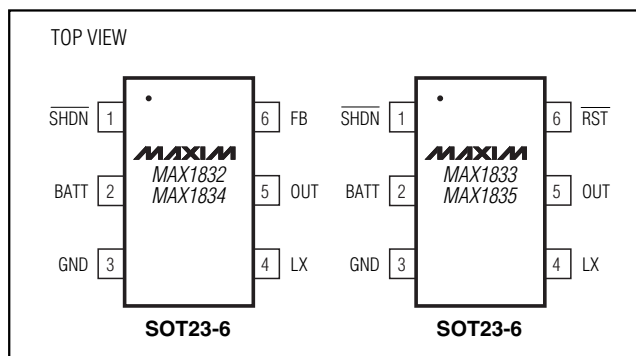

- ◆ Reverse Battery Protection for DC-DC Converter and Load
- ◆ Up to 90% Efficiency
- ◆ No External Diode or FETs Needed
- ◆ Internal Synchronous Rectifier
- ◆ 4µA Quiescent Current
- ◆ <1µA Shutdown Supply Current
- ◆ +1.5V to +5.5V Input Voltage Range
- ◆ Accurate $\overline{\text{SHDN}}$ Threshold for Low-Battery Cutoff
- ◆ BATT Connected to OUT in Shutdown for Backup Power (MAX1832/MAX1833)
- ◆ $\overline{\text{RST}}$ Output (MAX1833/MAX1835)
- ◆ Fixed +3.3V Output Voltage (MAX1833/MAX1835)
- ◆ Adjustable Output Voltage (MAX1832/MAX1834)
- ◆ Up to 150mA Output Current
- ◆ Tiny 6-Pin SOT23 Package

ABSOLUTE MAXIMUM RATINGS

BATT, LX to GND -6V to +6V
 LX to OUT -6V to +1V
 SHDN to GND -6V to ($V_{OUT} + 0.3V$)
 OUT, FB, RST TO GND -0.3V to +6V
 LX Current 1A
 Continuous Power Dissipation ($T_A = +70^\circ C$)
 SOT23-6 (derate 9.1mW/ $^\circ C$ above $+70^\circ C$) (Note 1)....727mW

Operating Temperature Range $-40^\circ C$ to $+85^\circ C$
 Junction Temperature $+150^\circ C$
 Storage Temperature Range $-65^\circ C$ to $+150^\circ C$
 Lead Temperature (soldering, 10s) (Note 2) $+300^\circ C$

Note 1: Thermal properties are specified with product mounted on PC board with one square-inch of copper area and still air.

Note 2: This device is constructed using a unique set of packaging techniques that impose a limit on the thermal profile the device can be exposed to during solder attach and rework. This limit permits only the use of the solder profiles recommended in the industry-standard specification, IPC/JEDEC J-STD-020A, paragraph 7.6, Table 3 for the IR/VPR and Convection reflow. Preheating is required. Hand or wave soldering is not allowed.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

($V_{SHDN} = +1.5V$, $V_{OUT} = +3.3V$, $V_{BATT} = +2V$, $GND = 0$, $T_A = -40^\circ C$ to $+85^\circ C$. Typical values are at $T_A = +25^\circ C$, unless otherwise noted.) (Note 3)

High-Efficiency Step-Up Converters with Reverse Battery Protection in SOT23-6

Detailed Description

The MAX1832–MAX1835 compact, high-efficiency step-up converters feature 4 μ A quiescent supply current to ensure the highest possible efficiency over a wide load range. With a minimum +1.5V input voltage, these devices are well suited for applications with two alkaline cells, two nickel-metal-hydride (NiMH) cells, or one lithium ion (Li+) cell. For the MAX1832 and MAX1833, the battery is connected to OUT through the inductor and an internal PFET when $\overline{\text{SHDN}}$ is low. This allows the input battery to be used as a backup or real-time clock supply when the converter is off by eliminating the voltage drop across the PFET body diode.

The MAX1832–MAX1835 are ideal for low-power applications where ultra-small size is critical. These devices feature built-in synchronous rectification that significantly improves efficiency and reduces size and cost by eliminating the need for an external Schottky diode. Furthermore, these devices are the industry's first boost regulators to offer complete reverse battery protection. This proprietary design protects the battery, IC, and the circuitry powered by the IC in the event the input batteries are connected backwards.

Control Scheme

A current-limited control scheme is a key feature of the MAX1832–MAX1835. This scheme provides ultra-low quiescent current and high efficiency over a wide output current range. There is no oscillator. The inductor current is limited by the 0.5A N-channel current limit or by the 5 μ s switch maximum on-time. Following each on-cycle, the inductor current must ramp to zero before another cycle may start. When the error comparator senses that the output has fallen below the regulation threshold, another cycle begins.

An internal synchronous rectifier eliminates the need for an external Schottky diode reducing cost and board space. While the inductor discharges, the P-channel MOSFET turns on and shunts the MOSFET body diode. As a result, the rectifier voltage drop is significantly reduced, improving efficiency without adding external components.

Reverse Battery Protection

The MAX1832–MAX1835 have a unique proprietary design that protects the battery, IC, and circuitry powered by the IC in the event that the input batteries are connected backwards. When the batteries are connected correctly, the reverse battery protection N-channel MOSFET is on and the device operates normally. When the batteries are connected backwards, the

reverse battery protection N-channel MOSFET opens, protecting the device and load (Figures 2 and 3). Previously, this level of protection required additional circuitry and reduced efficiency due to added components in the battery current path.

Applications Information

Shutdown

When $\overline{\text{SHDN}}$ is low, the device is off and no current is drawn from the battery. When $\overline{\text{SHDN}}$ is high, the device is on. If $\overline{\text{SHDN}}$ is driven from a logic-level output, the logic high (on) level should be referenced to V_{OUT} to avoid intermittent turn on. If $\overline{\text{SHDN}}$ is not used at all, connect it to OUT. With $\overline{\text{SHDN}}$ connected to OUT, the MAX1834/MAX1835 startup voltage (1.65V) is slightly higher, due to the voltage across the PFET body diode. The $\overline{\text{SHDN}}$ pin has reverse battery protection.

In shutdown, the MAX1832/MAX1833 connect the battery input to the output through the inductor and the internal synchronous rectifier PFET. This allows the input battery (rather than a separate backup battery) to provide backup power for devices such as an idled microcontroller, SRAM, or real-time clock, without the usual diode forward drop. If the output has a residual voltage during shutdown, a small amount of energy will be transferred from the output back to the input immediately after shutdown. This energy transfer may cause a slight momentary “bump” in the input voltage. The magnitude and duration of the input bump are related to the ratio of C_{IN} and C_{OUT} and the ability of the input to sink current. With battery input sources, the bump will be negligible, but with power-supply inputs (that typically cannot sink current), the bump may be 100s of mV.

In shutdown, the MAX1834/MAX1835 do not turn on the internal PFET and thus do not have an output-to-input current path in shutdown. This allows a separate backup battery, such as a Li+ cell, to be diode-connected at the output, without leakage current flowing to the input. The MAX1834/MAX1835 still have the typical input-to-output current path from the battery to the output, through the PFET body diode, in shutdown.

Low-Battery Cutoff

The $\overline{\text{SHDN}}$ trip threshold of the MAX1832–MAX1835 can be used as a voltage detector, with a resistor-divider, to power down the IC when the battery voltage falls to a set level (Figure 1). The $\overline{\text{SHDN}}$ trip threshold is 1.228V. To use a resistor-divider to set the shutdown voltage, select a value for R_3 in the 100k Ω to 1M Ω

High-Efficiency Step-Up Converters with Reverse Battery Protection in SOT23-6

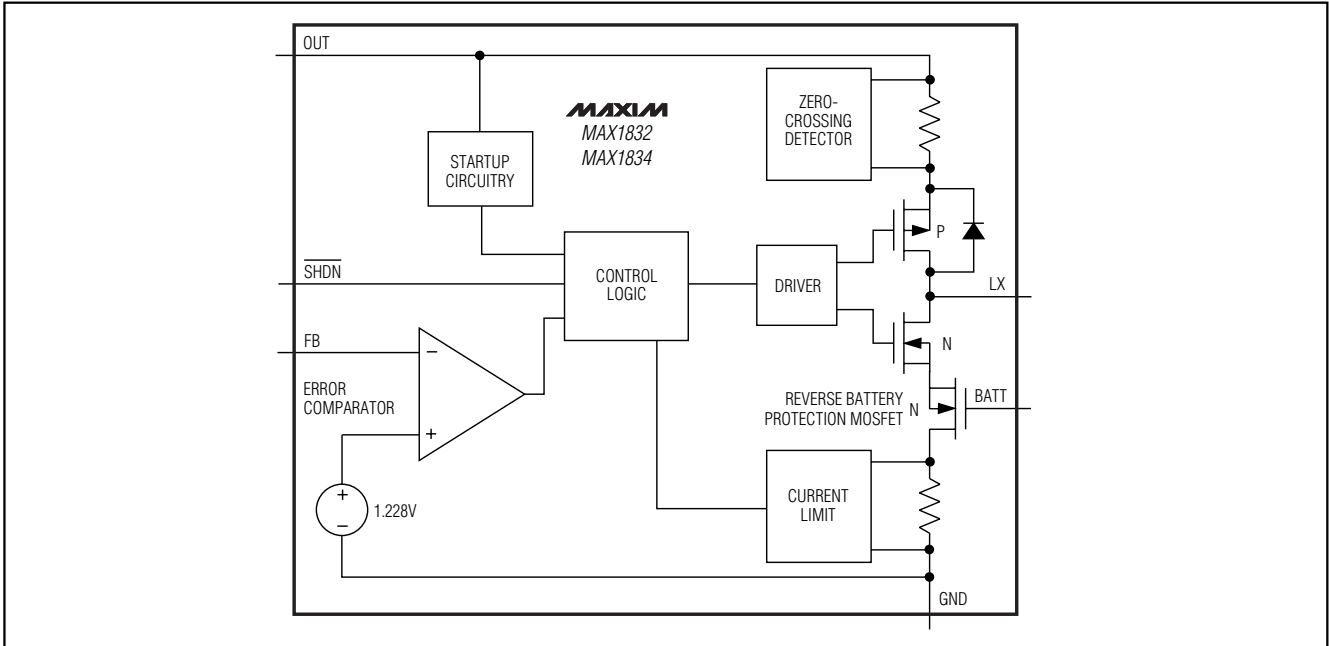

Figure 2. MAX1832/MAX1834 Simplified Functional Diagram

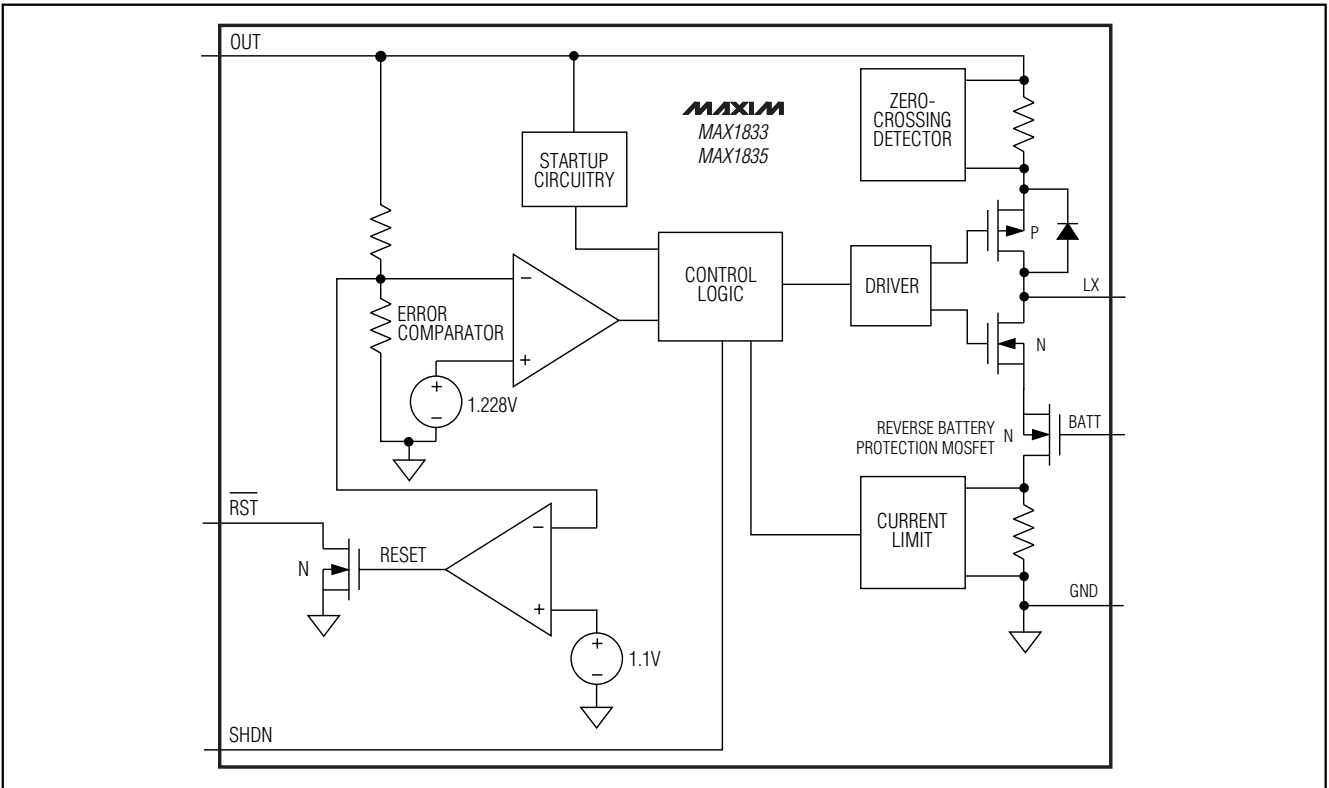

Figure 3. MAX1833/MAX1835 Simplified Functional Diagram

High-Efficiency Step-Up Converters with Reverse Battery Protection in SOT23-6

range to minimize battery drain. Calculate R4 as follows:

$$R4 = R3 \times (V_{OFF} / V_{SHDN} - 1)$$

V_{OFF} is the battery voltage at which the part will shut down and V_{SHDN} = 1.228V. Note that input ripple can sometimes cause false shutdowns. To minimize the effect of ripple, connect a low-value capacitor (C1) from SHDN to GND to filter out input noise. Select a C1 value such that the R4 × C1 time constant is above 2ms.

Power-On Reset

The MAX1833/MAX1835 provide a power-on reset output (RST). A 100kΩ to 1MΩ pullup resistor from RST to OUT provides a logic control signal. This open-drain output pulls low when the output is 10% below its regulation point. If not used, connect it to GND.

Setting the Output Voltage

The output voltage of the MAX1832/MAX1834 is adjustable from +2V to +5.5V, using external resistors R1 and R2 (Figure 1b). Since FB leakage is 20nA (max), select feedback resistor R1 to be 100kΩ to 1MΩ. Calculate R2 as follows:

$$R2 = R1 \left(\frac{V_{OUT}}{V_{FB}} - 1 \right)$$

where V_{FB} = 1.228V.

Inductor Selection

The control scheme of the MAX1832-MAX1835 permits flexibility in choosing an inductor. A 10μH inductor performs well for most applications, but values from 4.7μH to 100μH may also be used. Small inductance values typically offer smaller physical size. Large inductance values minimize output ripple but reduce output power. Output power is reduced when the inductance is large enough to prevent the maximum current limit (525mA) from being reached before the maximum on-time (5μs) expires.

For maximum output current, choose L such that:

$$\frac{V_{BATT(MAX)}(1\mu s)}{0.525A} < L < \frac{V_{BATT(MIN)}(5\mu s)}{0.525A}$$

$$I_{OUT(MAX)} = \frac{0.525A}{2} \times \frac{V_{BATT(MIN)} - \frac{0.525A}{2} (R_{NCH} + R_{IND})}{V_{OUT}}$$

where R_{IND} is the inductor series resistance, and R_{NCH} is the R_{DS(ON)} of the N-channel MOSFET (0.4Ω typ).

Table 1. Suggested Inductors and Suppliers

MANUFACTURER	INDUCTOR	PHONE
Coilcraft	DS1608C-103 DO1606T-103	847-639-6400
Sumida	CDRH4D18-100 CR43-100	847-956-0666
Murata	LQH4N100K	814-237-1431

Table 2. Suggested Surface-Mount Capacitors and Manufacturers

VALUE (μF)	DESCRIPTION	MANUFACTURER	PHONE
4.7 to 47	594/595 D-series tantalum	Sprague	603-224-1961
	TAJ, TPS-series tantalum	AVX	803-946-0690
4.7 to 10	X7R ceramic	TDK	847-390-4373
4.7 to 22	X7R ceramic	Taiyo Yuden	408-573-4150

Capacitor Selection

Choose an output capacitor to achieve the desired output ripple percentage.

$$C_{OUT} > \frac{0.5 \times L \times 0.525A^2}{r\% \times V_{OUT}^2}$$

where r is the desired output ripple in %. A 10μF ceramic capacitor is a good starting value. The input capacitor reduces the peak current drawn from the battery and can be the same value as the input capacitor. A larger input capacitor can be used to further reduce ripple and improve efficiency.

PC Board Layout and Grounding

Careful printed circuit layout is important for minimizing ground bounce and noise. Keep the IC's GND pin and the ground leads of the input and output filter capacitors less than 0.2in (5mm) apart. In addition, keep all connections to the FB and LX pins as short as possible. In particular, when using external feedback resistors,
