

bq2058

Lithium Ion Pack Supervisor for 3- and 4-Cell Packs

Features

- Protects and individually monitors three or four Li-Ion series cells for overvoltage, undervoltage
- Monitors pack for overcurrent
- Designed for battery pack integration
- Minimal external components
- Drives external FET switches
- Selectable overvoltage (V_{OV}) thresholds
 - Mask-programmable by Texas Instruments
 - Standard version—4.25V
- Supply current: 25 μ A typical
- Sleep current: 0.7 μ A typical
- 16-pin 150-mil narrow SOIC

General Description

The bq2058 Lithium Ion Pack Supervisor is designed to control the charge and discharge cell voltages for three or four lithium ion (Li-Ion) series cells, accommodating battery packs containing series/parallel configurations. The low operating current does not over-discharge the cells during periods of storage and does not significantly increase the system discharge load. The bq2058 can be part of a low-cost Li-Ion charge control system within the battery pack.

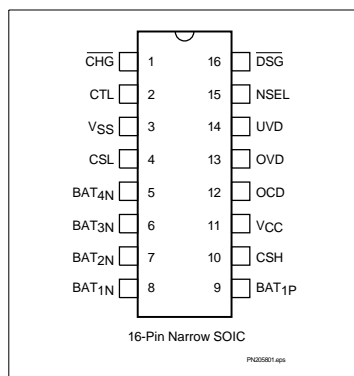

The bq2058 controls two external FETs to limit the charge and discharge potentials. The bq2058 allows charging when each individual cell voltage is below V_{OV} (overvoltage limit). If the voltage on any cell exceeds V_{OV} for a user-configurable delay period (t_{OVD}), the \overline{CHG} pin is driven high, shutting off charge to the battery pack. This safety feature pre-

vents overcharge of any cell within the battery pack. After an overvoltage condition occurs, each cell must fall below V_{CE} (charge enable voltage) for the bq2058 to re-enable charging.

The bq2058 protects batteries from overdischarge. If the voltage on any cell falls below V_{UV} (undervoltage limit) for a user-configurable delay period (t_{UVD}), the \overline{DSG} output is driven high, shutting off the battery discharge. This safety feature prevents overdischarge of any cell within the battery pack.

The bq2058 also stops discharge on detection of an overcurrent condition, such as a short circuit. If an overcurrent condition occurs for a user-configurable delay period (t_{OCD}), the \overline{DSG} output is driven high, disconnecting the load from the pack. \overline{DSG} remains high until removal of the short circuit or overcurrent condition.

Pin Connections

Pin Names

\overline{CHG}	Charge control output	\overline{DSG}	Discharge control output
CTL	Pack disable input	NSEL	3- or 4-cell selection
VSS	Low potential input	UVD	Undervoltage delay input
CSL	Current sense low-side input	OVD	Overvoltage delay input
BAT4N	Battery 4 negative input	OCD	Overcurrent delay input
BAT3N	Battery 3 negative input	VCC	High potential input
BAT2N	Battery 2 negative input	CSH	Current sense high-side input
BAT1N	Battery 1 negative input	BAT1P	Battery 1 positive input

Pin Descriptions

$\overline{\text{CHG}}$	Charge control output This push-pull output controls the charge path to the battery pack. Charging is allowed when low.	$\overline{\text{DSG}}$	Discharge control output This push-pull output controls the discharge path to the battery pack. Discharge is allowed when low.
CTL	Pack disable input When high, this input allows an external source to disable the pack by making both $\overline{\text{DSG}}$ and $\overline{\text{CHG}}$ inactive. For normal operation, the CTL pin is low.	NSEL	Number of cells input This input selects the number of series cells in the pack. NSEL should connect to V_{CC} for four cells and to V_{SS} for three cells.
V_{SS}	Low potential input	UVD	Undervoltage delay input This input uses an external capacitor to V_{CC} to set the undervoltage delay timing.
CSL	Overcurrent sense low-side input This input is connected between the low-side discharge FET (or sense resistor) and BAT _{4N} to enable overcurrent sensing in the battery pack's ground path.	OVD	Overvoltage delay input This input uses an external capacitor to V_{CC} to set the overvoltage delay timing.
BAT_{4N}	Battery 4 negative input This input is connected to the negative terminal of the cell designated BAT4 in Figure 2.	OCD	Overcurrent delay input This input uses an external capacitor to V_{CC} to set the overcurrent delay timing.
BAT_{3N}	Battery 3 negative input This input is connected to the negative terminal of the cell designated BAT3 in Figure 2.	V_{CC}	High potential input
BAT_{2N}	Battery 2 negative input This input is connected to the negative terminal of the cell designated BAT2 in Figure 2.	CSH	Overcurrent sense high-side input This input is connected between the high-side discharge FET (or sense resistor) and BAT _{1P} to enable overcurrent sense in the battery pack's positive supply path.
BAT_{1N}	Battery 1 negative input This input is connected to the negative terminal of the cell designated BAT1 in Figure 2.	BAT_{1P}	Battery 1 positive input This input is connected to the positive terminal of the cell designated BAT1 in Figure 2.

Table 1. Pin Configuration for 3- and 4-Series Cells

Number of Cells	Configuration Pins	Battery Pins
3 cells	BAT _{1N} tied to BAT _{1P} NSEL = V_{SS}	BAT _{1N} – Positive terminal of first cell
		BAT _{2N} – Negative terminal of first cell
		BAT _{3N} – Negative terminal of second cell
		BAT _{4N} – Negative terminal of third cell
4 cells	NSEL = V_{CC}	BAT _{1P} – Positive terminal of first cell
		BAT _{1N} – Negative terminal of first cell
		BAT _{2N} – Negative terminal of second cell
		BAT _{3N} – Negative terminal of third cell
		BAT _{4N} – Negative terminal of fourth cell

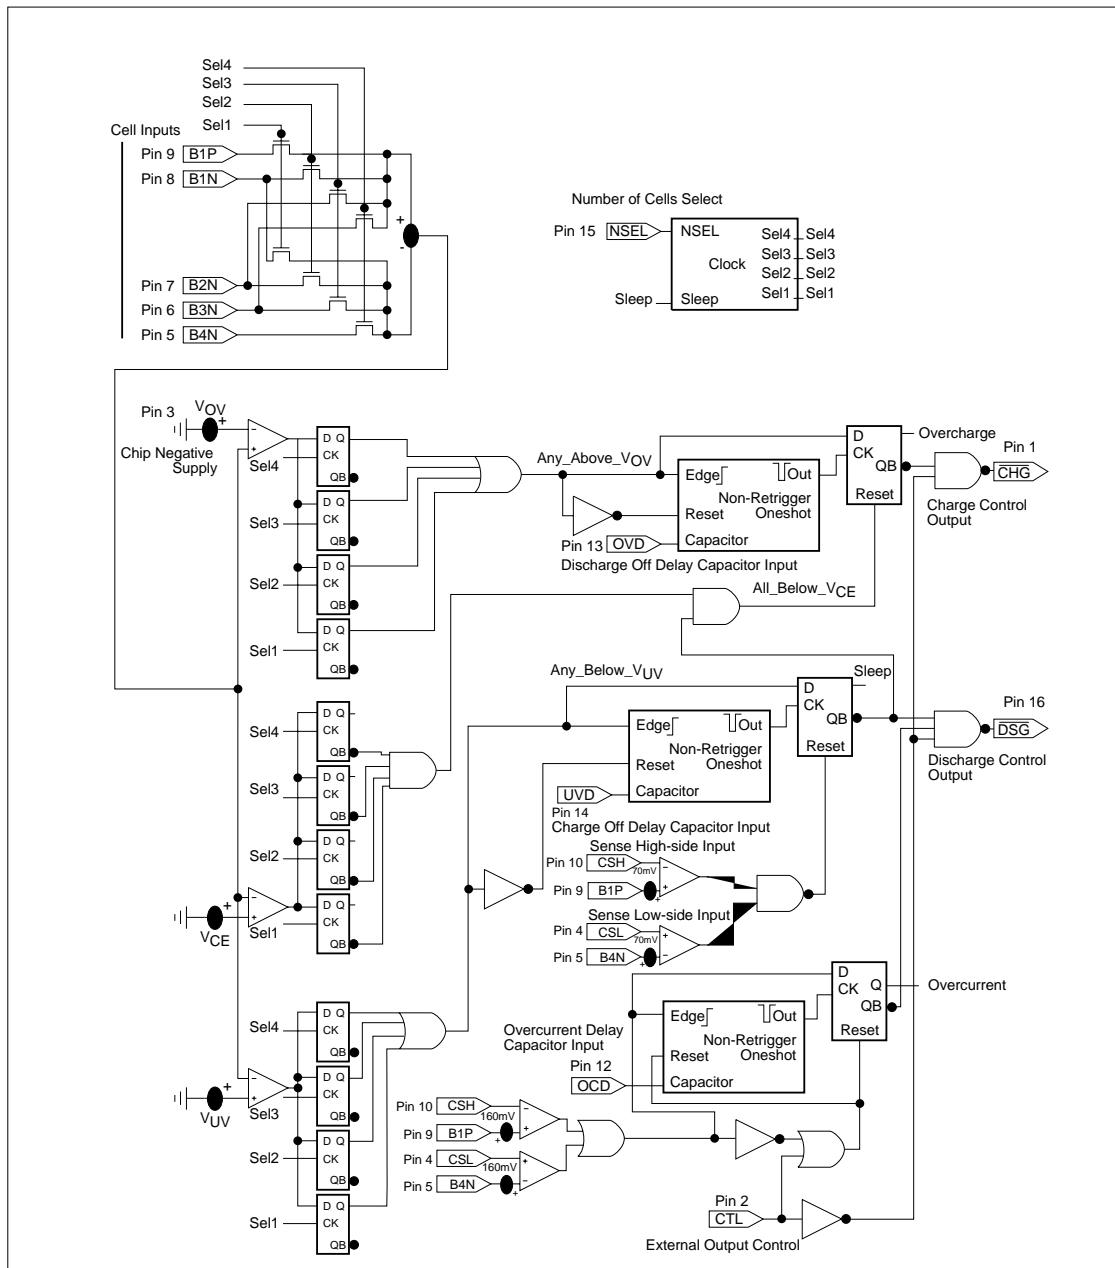

Figure 1. Block Diagram

Low-Power Sleep Mode

The bq2058 enters the low-power sleep mode in two different ways:

1. On initial power-up
2. After the detection of an undervoltage condition— V_{UV}

When the bq2058 enters the low-power sleep mode, \overline{DSG} is driven high and the device consumes 0.7 μ A (typical). The bq2058 only comes out of low-power sleep mode when a valid charge-detect condition exists.

Charge Detect

The bq2058 continuously monitors for a charge-detect condition. A valid charge-detect condition exists when either of the conditions is true:

$$CSL < BAT_{4N} - 70mV (V_{CD})$$

$$CSH > BAT_{1P} + 70mV (V_{CD})$$

A valid charge-detect enables the \overline{DSG} output, allowing charging of the lithium ion cells. This is accomplished by applying the charging supply to the pack.

Undervoltage

Undervoltage (or overdischarge) protection is asserted when any cell voltage drops below the V_{UV} threshold and remains below the V_{UV} threshold for a time exceeding a user-configurable delay (t_{UVD}). The \overline{DSG} output is driven high disabling the discharge of the pack. The bq2058 then enters the low-power sleep mode.

Overvoltage

Overvoltage (or overcharge) protection is asserted when any cell voltage exceeds the V_{OV} threshold and remains above the V_{OV} threshold for a time exceeding a user-configurable delay (t_{OVD}). The CHG pin is driven high, disabling charge into the battery pack. Charging is disabled until a valid charge enable exists. See Charge Enable section.

Important note: If any battery pin floats (BAT_{1P} , BAT_{1N-4N}), the bq2058 assumes an overvoltage has occurred.

Because of different manufacturers specifications for overvoltage thresholds, the bq2058 can be available with different V_{OV} options. Table 2 summarizes these different voltage thresholds.

Table 2. Overvoltage Threshold Options

Part No.	V_{OV} Limit
bq2058	4.25V
bq2058C	4.325V
bq2058R	4.35V

The overvoltage threshold limits are programmed by Texas Instruments. The bq2058 is the standard option that is more readily available for sampling and prototyping purposes. Please contact your Texas Instruments Sales Representative for other voltage threshold and tolerance options.

Charge Enable

A valid charge enable indicates that an overvoltage (overcharge) condition no longer exists and that the pack is ready to accept further charge. Once overvoltage protection is asserted, charging will not be enabled until all cell voltages fall below V_{CE} . The V_{CE} threshold is a function of V_{OV} , and changes with different V_{OV} limits.

$$V_{CE} = V_{OV} - 150mV$$

Overcurrent

The bq2058 detects an overcurrent (or short circuit) condition only in the discharge direction. Overcurrent protection is asserted when either of the conditions occurs and remains for a time exceeding a user-configurable delay (t_{OCD}):

$$CSL > BAT_{4N} + V_{OCL}$$

$$CSH < BAT_{1P} - V_{OCH}$$

where

$$V_{OCL} = 160mV \text{ (low-side detect)}$$

$$V_{OCH} = 160mV \text{ (high-side detect)}$$

When either of these conditions occurs, \overline{DSG} is driven high, disconnecting the load from the pack. \overline{DSG} remains high until both of the voltage conditions are false, indicating removal of the short-circuit condition. The user can facilitate clearing these conditions by inserting the battery pack into a charger.

The low-side overcurrent sense can be disabled by connecting CSL to BAT_{4N} . This ensures that CSL is never greater than BAT_{4N} . If low-side detection is disabled, high-side detection must be used with CSH.

bq2058

The FETs in the charge/discharge path controlled by the CHG and DSG pins affect the overcurrent level. The on-resistance of these FETs need to be taken into account when determining overcurrent levels.

Condition	CHG pin	DSG pin
Normal operation	Low	Low
Overvoltage	High	Low
Undervoltage	Low	High
Overcurrent	Low	High
Floating battery input	High	Indeterminate
CTL = high	High	High

CHG and DSG States

The CHG and DSG output truth table is shown below.

The polarities of CHG and DSG are mask programmable at Texas Instruments. Push-pull vs. open-drain configuration is also mask-configurable at Texas Instruments. Please contact your Texas Instruments Sales Representative for availability of these variations.

Number of Cells

The user must configure the bq2058 for three- or four-series cell operation. For a three-cell pack, NSEL should be tied directly to V_{SS}. For a four-cell pack, NSEL should be connected directly to V_{CC}.

Number of Series Cells	NSEL
3-cell	Tied to V _{SS}
4-cell	Tied to V _{CC}

Pack Disable Input-CTL

The CTL pin is used to electrically disconnect the battery from the pack terminals through an externally supplied signal. When CTL is taken high, CHG and DSG are driven high. Any load on the pack terminals will be interpreted as an overcurrent condition by the bq2058 with the overcurrent delay timer held in reset. When the CTL pin is driven low, the overcurrent delay timer is allowed to start. If the programmed delay (t_{OCD}) is too short, the overcurrent recovery circuit, if implemented, will be unable to correct the overcurrent situation prior to the delay time-out. It is recommended that a delay time of greater than 10ms (C_{OCD} ≥ 0.01μF) be used if the CTL pin function is used.

Important note: If CTL floats, it is internally pulled high making both DSG and CHG inactive, thus disabling the pack. If CTL is not used, it should be tied to V_{SS}.

The polarity of CTL is mask programmable at Texas Instruments. Please contact your Texas Instruments Sales Representative for other polarity options.

Protection Delay Timers

The delay time between the detection of an overcurrent, overvoltage, or undervoltage condition and the deactivation of the CHG and/or DSG outputs is user-configurable by the selection of capacitor values between V_{CC} and OCD, OVD, and UVD pins (respectively). See Table 3 below.

The fault condition must persist through the entire delay period, or the bq2058 may not deactivate either FET control output.

Figure 3 shows a step-by-step event cycle for the bq2058.

Table 3. Protection Delay Timers

Protection Feature	Delay Period	Capacitor from V _{CC} to:	Typical		Tolerance
			Capacitor	Time	
Overcurrent	t _{OCD}	OCD	0.010μF	12ms	±40%
Overvoltage	t _{OVD}	OVD	0.100μF	950ms	±40%
Undervoltage	t _{UVD}	UVD	0.100μF	950ms	±40%

- Notes:**
- The delay time versus capacitance can be approximated by the following equations:
 For t_{OCD}: $t(s) \approx 1.2 * C(\mu F)$, where $C \geq 0.001\mu F$
 For t_{OVD}, t_{UVD}: $t(s) \approx 9.5 * C(\mu F)$, where $C \geq 0.01\mu F$
 - Overvoltage and undervoltage conditions are sampled by the bq2058. The delay in Table 2 is in addition to the time required for the bq2058 to detect the violation, which may vary from 0 to 160ms depending on where in the sampling period the violation occurs. Overcurrent is continuously monitored and is subject to a delay of approximately 1.5ms.

SLUS070A—JULY 2000

Figure 3. Protector Event Diagram

Event Definition

- 0: The bq2058 is in the low-power sleep mode because one or more of the cell voltages are below V_{UV} .
- 1: A charger is applied to the pack, causing the difference between CSH and BAT_{1P} to become greater than 70mV. This awakens the bq2058, and the discharge pin DSG goes low.
- 2: One or more cells charge to a voltage equal to V_{OV} , initiating the overvoltage delay timer.
- 3: The overvoltage delay time expires, causing \overline{CHG} to be driven high.
- 4: All cell voltages fall below V_{CE} , causing \overline{CHG} to be driven low.
- 5: Stop charging; apply a load.
- 6: An overcurrent condition is detected, initiating the overcurrent delay timer.
- 7: The overcurrent delay time expires, causing \overline{DSG} to be driven high.
- 8: The overcurrent condition is no longer present; \overline{DSG} is driven low.
- 9: Pin CTL is driven high; both \overline{DSG} and \overline{CHG} are driven high.
- 10: Pin CTL is driven low; both \overline{DSG} and \overline{CHG} resume their normal function.
- 11: One or more cells fall below V_{UV} , initiating the overdischarge delay timer.
- 12: Once the overdischarge delay timer expires, if any of the cells is below V_{UV} , the bq2058 drives DSG high and enters the low-power sleep mode.

Absolute Maximum Ratings

Symbol	Parameter	Value	Unit	Conditions
VCC	Supply voltage	18	V	Relative to VSS
TOPR	Operating temperature	-30 to +70	°C	
TSTG	Storage temperature	-55 to +125	°C	
TSOLDER	Soldering temperature	260	°C	For 10 seconds
IIN	Maximum input current	±100	μA	All pins except VCC, VSS

- Notes:**
- 1 Permanent device damage may occur if **Absolute Maximum Ratings** are exceeded. Functional operation should be limited to the Recommended DC Operating Conditions detailed in this data sheet. Exposure to conditions beyond the operational limits for extended periods of time may affect device reliability.
 - 2. Internal protection diodes are in place on every pin relative to VCC and VSS. See Figure 4.

Figure 4. Internal Protection Diodes

DC Electrical Characteristics ($T_A = T_{OPR}$)

Symbol	Parameter	Minimum	Typical	Maximum	Unit	Conditions/Notes
V _{OH}	Output high voltage	V _{CC} - 0.5	-	-	V	I _{OH} = 10μA, $\overline{\text{CHG}}$, $\overline{\text{DSG}}$
