TEA6324T

FEATURES

- Source selector for two stereo and one mono inputs
- Interface for noise reduction circuits
- Interface for external equalizer
- Volume and balance control
- Bass control with equalizer filters
- Treble control
- Mute control at audio signal zero crossing
- Fast mute control via I2C-bus
- Fast mute control via pin
- I2C-bus control for all functions
- Power supply with internal power-on reset.

GENERAL DESCRIPTION

The sound control circuit TEA6324T is an I²C-bus controlled stereo preamplifier for car radio hi-fi sound applications.

SCL	24	serial clock input (I ² C-bus)

Sound control circuit TEA6324T

FUNCTIONAL DESCRIPTION

The source selector selects one of 2 stereo inputs or the mono input. The maximum input signal voltage is $V_{i(rms)} = 2 \text{ V}$. The outputs of the source selector and the inputs of the following volume control parts are available at pins 7 and 8 for the left channel and pins 17 and 18 for the right channel. This offers the possibility of interfacing a noise reduction system.

The volume control function is split into two sections: volume I control block and volume II control block.

The control range of volume I is between +20 dB and -31 dB in steps of 1 dB. The volume II control range is between 0 dB and -55 dB in steps of 1 dB.

The recommended control range to be used is 86 dB (+20 to -66 dB) although in theory, a range of 106 dB (+20 to -86 dB) can be attained. The gain/attenuation setting of the volume I control block is common for both channels.

The volume I control block is followed by the bass control block. The frequency response of the bass control (see Fig.3) is provided for each channel by an external filter in combination with internal resistors. The adjustable range is between –18 and +18 dB in steps of 1.8 dB at 46 Hz.

The treble control block offers a control range between –12 and +12 dB in steps of 1.5 dB at 15 kHz. The filter characteristic is determined by a single capacitor of 5.6 nF for each channel in combination with internal resistors (see Fig.4).

The basic step width of treble control is 3 dB. The intermediate steps are obtained by switching 1.5 dB boost and 1.5 dB attenuation steps.

The bass and treble control functions can be switched off via I²C-bus. In this event the internal signal flow is disconnected. The connections B2L and B2R are outputs and TL and TR are inputs for inserting an external equalizer.

The last section of the circuit is the volume II block. The balance function uses the same control block. This is achieved by 2 independently controllable attenuators, one for each output. The control range of these attenuators is 55 dB in steps of 1 dB with an additional mute step.

The circuit provides 3 mute modes:

- Zero crossing mode mute via I²C-bus using 2 independent zero crossing detectors (ZCM, see Tables 2 and 8 and Fig.15)
- 2. Fast mute via MUTE pin (see Fig.9)

3. Fast mute via I²C-bus either by general mute (GMU, see Tables 2 and 8) or volume II block setting (see Table 4).

The mute function is performed immediately if ZCM is cleared (ZCM = 0). If the bit is set (ZCM = 1) the mute is activated after changing the GMU bit. The actual mute switching is delayed until the next zero crossing of the audio frequency signal. Two comparators are built-in to provide independent mute switches to control each of the audio channels (left and right).

To avoid a large delay of mute switching when very low frequencies are processed, the maximum delay time is limited to typically 100 ms by an integrated timing circuit and an external capacitor ($C_m = 10 \text{ nF}$, see Fig.9). This timing circuit is triggered by reception of a new data word for the switch function which includes the GMU bit. After a discharge and charge period of an external capacitor the muting switch follows the GMU bit, only if no zero crossing was detected during that time.

The mute function can also be controlled externally (see Fig.9). If the mute pin is switched to ground all outputs are muted immediately (hardware mute). This mute request overwrites all mute controls via the I²C-bus for the time the pin is held LOW. The hardware mute position is not stored in the TEA6324T.

Typically, the turn on/off can be used to avoid AF output. This can be caused by the input signal from preceding stages, which may produce output during a drop of V_{CC} . To avoid this, the mute must be set prior to a V_{CC} drop and can be achieved either by I²C-bus control, or by grounding the MUTE pin.

In cases where there is no mute in the application before turn off, a supply voltage drop of more than $1 \times V_{BE}$ will result in a mute during the voltage drop.

The power supply should include a V_{CC} buffer capacitor, which provides a discharging time constant. If the input signal does not disappear after turn off the input will become audible after a certain time. A 4.7 k Ω resistor discharges the V_{CC} buffer capacitor, because the internal current of the IC does not discharge it completely.

The hardware mute function is ideal for use in Radio Data System (RDS) applications. The zero crossing mute avoids modulation plops. This feature is an advantage for mute during changing presets and/or sources (e.g. traffic announcement during cassette playback).

TEA6324T

LIMITING VALUES

In accordance with the Absolute Maximum Rating System (IEC 134).

SYMBOL	PARAMETER	CONDITIONS	MIN.	MAX.	UNIT

Notes to the characteristics

- 1. The indicated values for output power assume a 6 W power amplifier at 4 Ω with 20 dB gain and a fixed attenuator of 12 dB in front of it. Signal-to-noise ratios exclude noise contribution of the power amplifier.
- 2. The transmission contains: total initialization with MAD and subaddress for volume and 8 data words, see also definition of characteristics, clock frequency = 50 kHz, repetition burst rate = 400 Hz, maximum bus signal amplitude = 5 V (p-p).
- 3. The AC characteristics are in accordance with the I²C-bus specification. This specification, "The I²C-bus and how to use it", can be ordered using the code 9398 393 40011.

In cases where at the maximum volume position the 20 dB gain is not needed, it is recommended that the maximum boost gain should be used. This coupled with increased attenuation in the last section (volume II), results in a lower noise and offset voltage.

Selection of input signals by using the zero crossing mute mode

The zero cross mute mode provides for a selection of input sources (A and B) for both left and right channels. The following example (see Fig.15), shows a typical selection for the left input source signals IAL and IBL. The initial selection of these channels produces a modulation click. The click is determined by the difference of the signal values at the time of switching.

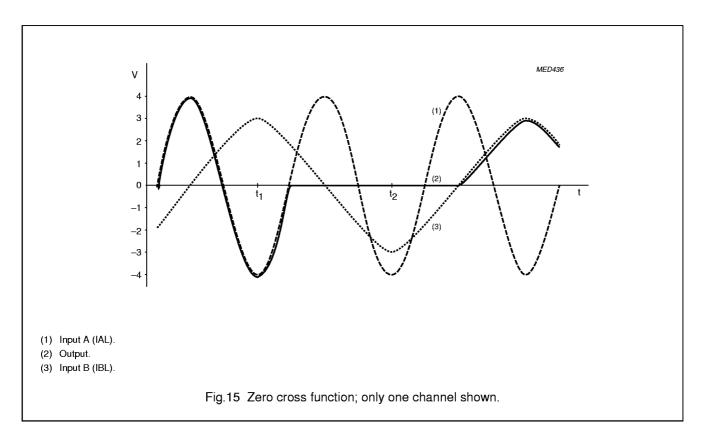

At t_1 the maximum possible difference between signals is 7 V (p-p) (see Fig.15) and gives a large click. Using the cross detector no modulation click is audible.

With the selection enabled at t_1 , the microcontroller sets the zero cross bit (ZCM = 1) and then the mute bit (GMU = 1) via the I^2 C-bus. The output signal follows the input A signal from -4 V, until the next zero crossing occurs and then activates mute.

After a fixed delay time at t₂, the microcontroller sends the bits for input switching and mute inactive.

The output signal remains muted until the next signal zero crossing of input B (IBL) occurs, and then follows that signal up to 3 V.

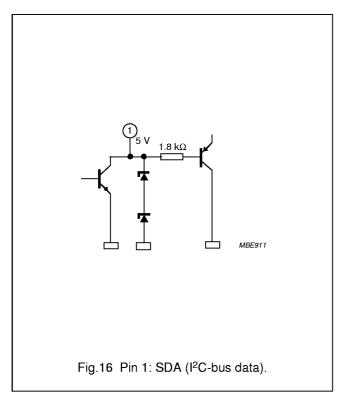

With a delay time of 40 ms (t_2-t_1), the external capacitor $C_m=3.3$ nF. This results with the zero cross function operating at the lowest frequency of 40 Hz determined by the C_m capacitor.

Sound control circuit TEA6324T

SOLDERING

Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our "IC Package Databook" (order code 9398 652 90011).

Reflow soldering

Reflow soldering techniques are suitable for all SO packages.

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary between 50 and 300 seconds depending on heating method. Typical reflow temperatures range from 215 to 250 °C.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 minutes at 45 °C.

Wave soldering

Wave soldering techniques can be used for all SO packages if the following conditions are observed:

- A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.
- The longitudinal axis of the package footprint must be parallel to the solder flow.
- The package footprint must incorporate solder thieves at the downstream end.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than 150 °C within 6 seconds. Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

Repairing soldered joints

Fix the component by first soldering two diagonally-opposite end leads. Use only a low voltage soldering iron (less than 24 V) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.
