Product Description

The PI5L102L CompactPCI Hot Swap Pull-up switch is a Quad 1:2 multiplexer. It is designed to switch the 1V precharge bias voltage and 10-kohm pull-up resistor connected to the CompactPCI bus signals during Hot Swap. Each switch can connect eight inputs (I_{An} to I_{Dn}) to a given pull-up voltage level.

In addition, the PI5L102 can be used to select 2.7 kohms/3.3V or 1.0 kohm/5V pull-ups for the system card PCI signal lines.

ON resistance is a low 7 ohms maximum and all eight switches are selected or disabled with a single CMOS/TTL compatible signal. For general-purpose applications, the PI5L102 can replace mechanical relays. In network systems, physical layer signals can be switched.

To reduce the insertion loss, the PI5L102 can be powered by a 6.2V Zener diode.

Notes:

1. For Max. or Min. conditions, use appropriate value specified under Electrical Characteristics for the applicable device type.
2. Typical values are at V_{CC} = 6.2V, T_A = 25°C ambient temperature.
3. Not more than one output should be shorted at one time. Duration of the test should not exceed one second.
4. Measured by voltage drop between I and Y pins at indicated current through the switch. ON resistance is determined by the lower of the voltages on the two (I, Y) pins.

Capacitance ($T_A = 25^\circ\text{C}$, $f = 1\text{ MHz}$)

Parameters ⁽¹⁾	Description	Test Conditions	Typ.	Max.	Units
C_{IN}	Input Capacitance	$V_{IN} = 0\text{V}$	4	6	pF

$C_{ON(Y_X)}^{(1,2)}$	Y_X Capacitance, Switch ON		24	32	

Note:

1. This parameter is determined by device characterization, but not production tested.
2. Switch ON Capacitance accounts for capacitance of both switch channels (I_{X0} & I_{X1}) ON at one time.
3. X = A, B, C, or D; N = 0 or 1

Notes:

1. For Max. or Min. conditions, use appropriate value specified under Electrical Characteristics for the applicable device.
2. Typical values are at $V_{CC} = 6.2\text{V}$, $T_A = 25^\circ\text{C}$ ambient temperature.
3. Per TTL driven input ($V_{IN} = 3.4\text{V}$, control inputs only); A and B pins do not contribute to I_{CC} .
4. This current applies to the control inputs only and represent the current required to switch internal capacitance at the specified frequency. The A and B inputs generate no significant AC or DC currents as they transition. This parameter is not tested, but is guaranteed by design.

Applications

Logic Inputs

The logic control inputs can be driven up to +5.5V regardless of the supply voltage. For example, given a +5.0V supply, \bar{E} may be driven low to 0V and high to 5.5V. Driving \bar{E} Rail-to-Rail[®] minimizes power consumption.

Power-Supply Sequencing

Proper power-supply sequencing is recommended for all CMOS devices. Always apply V_{CC} before applying signals to the input/output or control pins.

V_{CC} Bias Voltage vs R_{ON}

To keep R_{ON} to a minimum, it is recommended that the V_{CC} voltage be increased to a voltage between +6.0V and +6.5V (see Figure 5). The R_{ON} vs V_{IN} curve shows the effect of ON-resistance and input voltage which is exponential. Ideally an input voltage between 0.2V and 3.6V will keep R_{ON} in the flat part of the curve (ΔR_{ON} or flatness is ~2ohm).
