

General Description

The ICS842S104 is a PLL-based clock generator specifically designed for PCI Express™ Clock Generation 2 applications. This device generates either a 200MHz or 100MHz differential HSTL clock from an input reference of 25MHz. The input reference may be derived from an external source or by the addition of a 25MHz crystal to the on-chip crystal oscillator. An external reference is applied to the XTAL_IN pin with the XTAL_OUT pin left floating. The device offers spread spectrum clock output for reduced EMI applications. An I²C bus interface is used to enable or disable spread spectrum operation as well as select either a down spread value of -0.35% or -0.5%. The ICS842S104 is available in a lead-free 24-Lead package.

Features

- Four differential HSTL output pairs
- Crystal oscillator interface: 25MHz
- Output frequency: 100MHz or 200MHz
- RMS phase jitter @ 200MHz (12kHz – 20MHz): 1.27ps (typical)
- Cycle-to-cycle jitter: 25ps (maximum)
- I²C support with readback capabilities up to 400kHz
- Spread Spectrum for electromagnetic interference (EMI) reduction
- 3.3V core/1.5V to 2.0V output operating supply
- 0°C to 70°C ambient operating temperature
- Available lead-free (RoHS 6) package
- PCI Express Gen2 Jitter Compliant

Serial Data Interface

To enhance the flexibility and function of the clock synthesizer, a two-signal I²C serial interface is provided. Through the Serial Data Interface, various device functions, such as individual clock output buffers, can be individually enabled or disabled. The registers

associated with the serial interface initialize to their default setting upon power-up, and therefore, use of this interface is optional. Clock device register changes are normally made upon system initialization, if any are required.

Data Protocol

The clock driver serial protocol accepts byte write, byte read, block write and block read operations from the controller. For block write/read operation, the bytes must be accessed in sequential order from lowest to highest byte (most significant bit first) with the ability to stop after any complete byte has been transferred. For byte write and byte read operations, the system controller can access individually

indexed bytes. The offset of the indexed byte is encoded in the command code, as described in Table 3A.

The block write and block read protocol is outlined in Table 3B, while Table 3C outlines the corresponding byte write and byte read protocol. The slave receiver address is 11010010 (D2h).

Table 3A. Command Code Definition

NOTE: Characterized using an 18pF parallel resonant crystal.

AC Electrical Characteristics

Table 6. AC Characteristics, $V_{DD} = 3.3V \pm 5\%$, $T_A = 0^\circ C$ to $70^\circ C$

Symbol	Parameter	Test Conditions	Minimum	Typical	Maximum	Units
f_{MAX}	Output Frequency	FOUTCTL = 0		100		MHz
		FOUTCTL = 1		200		
f_{ref}	Reference frequency			25		MHz
$t_{REFCLK_HF_RMS}$	Phase Jitter RMS; NOTE 1, 2	$f = 200MHz$, 25MHz crystal input High Band: 1.5MHz - Nyquist (clock frequency/2)		0.95		ps
$t_{REFCLK_LF_RMS}$	Phase Jitter RMS; NOTE 1	$f = 200MHz$, 25MHz crystal input Low Band: 10kHz - 1.5MHz		0.31		ps
$t_{sk(o)}$	Output Skew; NOTE 2, 3				50	ps
$f_{jit}(\emptyset)$	Phase Jitter, RMS (Random)	200MHz, Integration Range: 12kHz – 20MHz		1.27		ps
$f_{jit}(cc)$	Cycle-to-Cycle Jitter	PLL Mode			25	ps
t_L	PLL Lock Time				60	ms
odc	Output Duty Cycle		48		52	%

NOTE: Electrical parameters are guaranteed over the specified ambient operating temperature range, which is established when the device is mounted in a test socket with maintained transverse airflow greater than 500 lfm. The device will meet specifications after thermal equilibrium has been reached under these conditions.

NOTE 1: RMS jitter after applying the two evaluation bands to the two transfer functions defined in the Common Clock Architecture and reporting the worst case results for each evaluation band. Maximum limit for PCI Express Generation 2 is 3.1 ps rms for $t_{REFCLK_HF_RMS}$ (High Band) and 3.0 ps RMS for $t_{REFCLK_LF_RMS}$ (Low Band). See IDT Application Note *PCI Express Reference Clock Requirements* and also the *PCI Express Application section* of this datasheet which show each individual transfer function and the overall composite transfer function.

NOTE 2: This parameter is defined in accordance with JEDEC Standard 65.

NOTE 3: Defined as skew between outputs at the same supply voltage and with equal load conditions.

Application Information

Power Supply Filtering Technique

As in any high speed analog circuitry, the power supply pins are vulnerable to random noise. To achieve optimum jitter performance, power supply isolation is required. The ICS842S104 provides separate power supplies to isolate any high switching noise from the outputs to the internal PLL. V_{DD} , V_{DDA} and V_{DDO} should be individually connected to the power supply plane through vias, and $0.01\mu\text{F}$ bypass capacitors should be used for each pin. *Figure 1* illustrates this for a generic V_{DD} pin and also shows that V_{DDA} requires that an additional 10Ω resistor along with a $10\mu\text{F}$ bypass capacitor be connected to the V_{DDA} pin.

Figure 1. Power Supply Filtering

Recommendations for Unused Input and Output Pins

Inputs:

LVC MOS Control Pins

All control pins have internal pullups; additional resistance is not required but can be added for additional protection. A $1\text{k}\Omega$ resistor can be used.

Outputs:

HSTL Outputs

All unused HSTL outputs can be left floating. We recommend that there is no trace attached. Both sides of the differential output pair should either be left floating or terminated.

Crystal Input Interface

The ICS842S104 has been characterized with 18pF parallel resonant crystals. The capacitor values, C1 and C2, shown in *Figure 2* below were determined using a 25MHz, 18pF parallel resonant

crystal and were chosen to minimize the ppm error. The optimum C1 and C2 values can be slightly adjusted for different board layouts.

Figure 2. Crystal Input Interface

Overdriving the XTAL Interface

The XTAL_IN input can accept a single-ended LVCMOS signal through an AC coupling capacitor. A general interface diagram is shown in *Figure 3A*. The XTAL_OUT pin can be left floating. The maximum amplitude of the input signal should not exceed 2V and the input edge rate can be as slow as 10ns. This configuration requires that the output impedance of the driver (R_o) plus the series resistance (R_s) equals the transmission line impedance. In addition,

matched termination at the crystal input will attenuate the signal in half. This can be done in one of two ways. First, R1 and R2 in parallel should equal the transmission line impedance. For most 50 Ω applications, R1 and R2 can be 100 Ω . This can also be accomplished by removing R1 and making R2 50 Ω . By overdriving the crystal oscillator, the device will be functional, but note, the device performance is guaranteed by using a quartz crystal.

Figure 3A. General Diagram for LVCMOS Driver to XTAL Input Interface

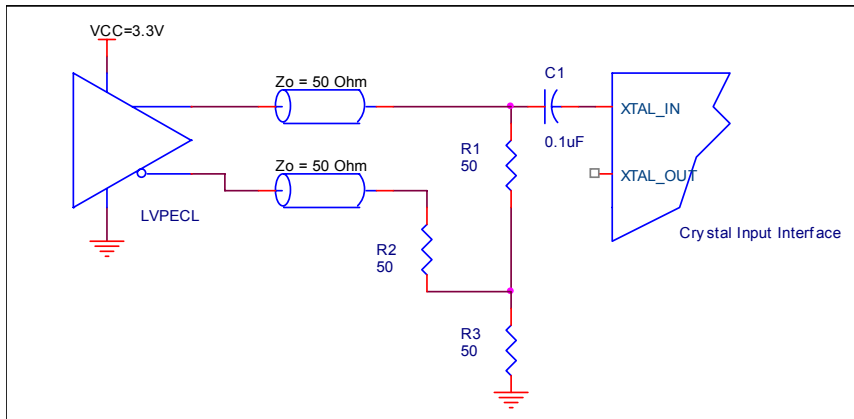

Figure 3B. General Diagram for LVPECL Driver to XTAL Input Interface

Termination for HSTL Outputs

Figure 4. HSTL Output Termination

Schematic Example

Figure 5 shows an example of ICS842S104 application schematic. In this example, the device is operated at $V_{DD} = 3.3V$ and $V_{DDO} = 1.8V$. Both input options are shown. The device can either be driven using a quartz crystal or a 3.3V LVCMOS signal. The $C1$ and $C2 = 18pF$ are recommended for frequency accuracy. For different board

layouts, the $C1$ and $C2$ may be slightly adjusted for optimizing frequency accuracy. The LVHSTL output driver termination examples are shown in this schematic. The decoupling capacitor should be located as close as possible to the power pin.

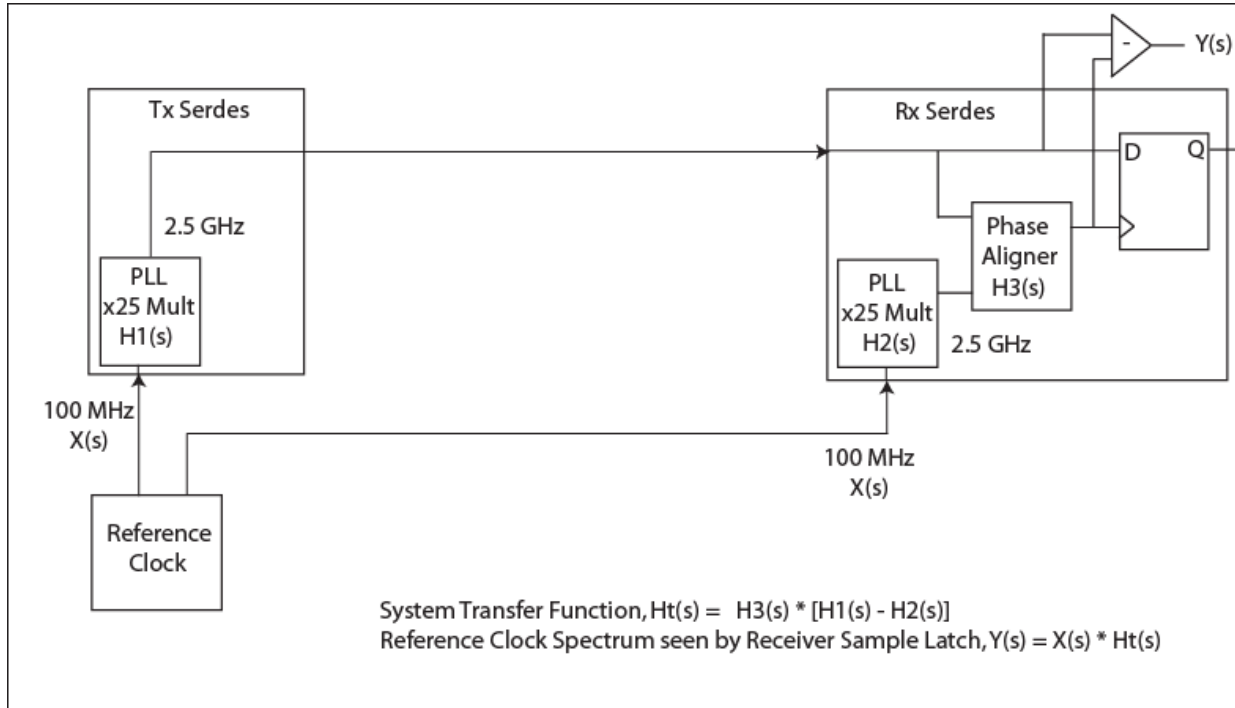

Figure 5. ICS842S104 Schematic Example

PCI Express Application Note

PCI Express jitter analysis methodology models the system response to reference clock jitter. The below block diagram shows the most

frequently used *Common Clock Architecture* in which a copy of the reference clock is provided to both ends of the PCI Express Link.

In the jitter analysis, the Tx and Rx serdes PLLs are modeled as well as the phase interpolator in the receiver. These transfer functions are called H1, H2, and H3 respectively. The overall system transfer function at the receiver is:

$$H_t(s) = H_3(s) \times [H_1(s) - H_2(s)]$$

The jitter spectrum seen by the receiver is the result of applying this system transfer function to the clock spectrum X(s) and is:

$$Y(s) = X(s) \times H_3(s) \times [H_1(s) - H_2(s)]$$

In order to generate time domain jitter numbers, an inverse Fourier Transform is performed on $X(s) * H_3(s) * [H_1(s) - H_2(s)]$.

For PCI Express Gen 1, one transfer function is defined and the evaluation is performed over the entire spectrum: DC to Nyquist (e.g for a 100MHz reference clock: 0Hz to 50MHz) and the jitter result is reported in peak-peak. For PCI Express Gen 2, two transfer functions are defined with 2 evaluation ranges and the final jitter number is reported in rms. The two evaluation ranges for PCI Express Gen 2 are 10kHz - 1.5MHz (Low Band) and 1.5MHz - Nyquist (High Band). The below plots show the individual transfer functions as well as the overall transfer function Ht. The respective -3 dB pole frequencies for each transfer function are labeled as F1 for transfer function H1, F2 for H2, and F3 for H3. For a more thorough overview of PCI Express jitter analysis methodology, please refer to IDT Application Note *PCI Express Reference Clock Requirements*.

Power Considerations

This section provides information on power dissipation and junction temperature for the ICS842S104. Equations and example calculations are also provided.

1. Power Dissipation.

The total power dissipation for the ICS842S104 is the sum of the core power plus the power dissipated in the load(s). The following is the power dissipation for $V_{DD} = 3.3V + 5\% = 3.465V$, which gives worst case results.

NOTE: Please refer to Section 3 for details on calculating power dissipated in the load.

- The maximum current at 70°C is as follows:

$$I_{DD_MAX} = 101.7mA$$

$$I_{DDA_MAX} = 19.4mA$$

- Power (core)_{MAX} = $V_{DD_MAX} * (I_{DD_MAX} + I_{DDA_MAX}) = 3.465V * (101.7mA + 19.4mA) = 419.6mW$
- Power (outputs)_{MAX} = **32mW/Loaded Output pair**
If all outputs are loaded, the total power is $4 * 32mW = 128mW$

Total Power_{MAX} (3.465V, with all outputs switching) = $419.6mW + 128mW = 547.6mW$

2. Junction Temperature.

Junction temperature, T_j , is the temperature at the junction of the bond wire and bond pad directly affects the reliability of the device. The maximum recommended junction temperature for HiPerClockS devices is 125°C. Limiting the internal transistor junction temperature, T_j , to 125°C ensures that the bond wire and bond pad temperature remains below 125°C.

The equation for T_j is as follows: $T_j = \theta_{JA} * Pd_total + T_A$

T_j = Junction Temperature

θ_{JA} = Junction-to-Ambient Thermal Resistance

Pd_total = Total Device Power Dissipation (example calculation is in section 1 above)

T_A = Ambient Temperature

In order to calculate junction temperature, the appropriate junction-to-ambient thermal resistance θ_{JA} must be used. Assuming no air flow and a multi-layer board, the appropriate value is 77.5°C/W per Table 7 below.

Therefore, T_j for an ambient temperature of 70°C with all outputs switching is:

$$70^\circ C + 0.548W * 77.5^\circ C/W = 112.5^\circ C. \text{ This is below the limit of } 125^\circ C.$$

This calculation is only an example. T_j will obviously vary depending on the number of loaded outputs, supply voltage, air flow and the type of board (multi-layer).

Table 7. Thermal Resistance θ_{JA} for 24 Lead TSSOP, Forced Convection

Meters per Second	θ_{JA} by Velocity		
	0	1	2.5
Multi-Layer PCB, JEDEC Standard Test Boards	77.5°C/W	73.2°C/W	71.0°C/W

3. Calculations and Equations.

The purpose of this section is to calculate the power dissipation for the HSTL output pair.

HSTL output driver circuit and termination are shown in *Figure 6*.

Figure 6. HSTL Driver Circuit and Termination

To calculate worst case power dissipation into the load, use the following equations which assume a 50Ω load.

Pd_H is power dissipation when the output drives high.

Pd_L is the power dissipation when the output drives low.

$$Pd_H = (V_{OH_MAX}/R_L) * (V_{DD_MAX} - V_{OH_MAX})$$

$$Pd_L = (V_{OL_MAX}/R_L) * (V_{DD_MAX} - V_{OL_MAX})$$

$$Pd_H = (1.2V/50\Omega) * (2.0V - 1.2V) = 19.2mW$$

$$Pd_L = (0.4V/50\Omega) * (2.0V - 0.4V) = 12.8mW$$

$$\text{Total Power Dissipation per output pair} = Pd_H + Pd_L = \mathbf{32mW}$$
