## 54SX Family FPGAs

## Leading Edge Performance

- 320 MHz Internal Performance
- 3.7 ns Clock-to-Out (Pin-to-Pin)
- 0.1 ns Input Set-Up
- 0.25 ns Clock Skew

## Specifications

- 12,000 to 48,000 System Gates
- Up to 249 User-Programmable I/O Pins
- Up to 1080 Flip-Flops
- $0.35 \mu$ CMOS

## Features

- 66 MHz PCl
- CPLD and FPGA Integration
- Single Chip Solution
- $100 \%$ Resource Utilization with $100 \%$ Pin Locking
- 3.3V Operation with 5.0V Input Tolerance
- Very Low Power Consumption
- Deterministic, User-Controllable Timing
- Unique In-System Diagnostic and Debug capability with Silicon Explorer II
- Boundary Scan Testing in Compliance with IEEE Standard 1149.1 (JTAG)
- Secure Programming Technology Prevents Reverse Engineering and Design Theft

## General Description

Actel's SX family of FPGAs features a sea-of-modules architecture that delivers device performance and integration levels not currently achieved by any other FPGA architecture. SX devices greatly simplify design time, enable dramatic reductions in design costs and power consumption, and further decrease time to market for performance-intensive applications.
Actel's SX architecture features two types of logic modules, the combinatorial cell ( C -cell) and the register cell ( R -cell), each optimized for fast and efficient mapping of synthesized logic functions. The routing and interconnect resources are in the metal layers above the logic modules, providing optimal use of silicon. This enables the entire floor of the device to be spanned with an uninterrupted grid of fine-grained, synthesis-friendly logic modules (or "sea-of-modules"), which reduces the distance signals have to travel between logic modules. To minimize signal propagation delay, SX devices employ both local and general routing resources. The high-speed local routing resources (DirectConnect and FastConnect) enable very fast local signal propagation that is optimal for fast counters, state
machines, and datapath logic. The general system of segmented routing tracks allows any logic module in the array to be connected to any other logic or I/O module. Within this system, propagation delay is minimized by limiting the number of antifuse interconnect elements to five ( 90 percent of connections typically use only three antifuses). The unique local and general routing structure featured in SX devices gives fast and predictable performance, allows 100 percent pin-locking with full logic utilization, enables concurrent PCB development, reduces design time, and allows designers to achieve performance goals with minimum effort.
Further complementing SX's flexible routing structure is a hard-wired, constantly loaded clock network that has been tuned to provide fast clock propagation with minimal clock skew. Additionally, the high performance of the internal logic has eliminated the need to embed latches or flip-flops in the I/O cells to achieve fast clock-to-out or fast input set-up times. SX devices have easy-to-use I/O cells that do not require HDL instantiation, facilitating design re-use and reducing design and verification time.

## SX Family Architecture

The SX family architecture was designed to satisfy next-generation performance and integration requirements for production-volume designs in a broad range of applications.

## Programmable Interconnect Element

The SX family provides efficient use of silicon by locating the routing interconnect resources between the Metal 2 (M2) and Metal 3 (M3) layers (Figure 1). This completely eliminates the channels of routing and interconnect resources between logic modules (as implemented on SRAM FPGAs and previous generations of antifuse FPGAs), and enables the entire floor of the device to be spanned with an uninterrupted grid of logic modules.
Interconnection between these logic modules is achieved using Actel's patented metal-to-metal programmable
antifuse interconnect elements, which are embedded between the M2 and M3 layers. The antifuses are normally open circuit and, when programmed, form a permanent low-impedance connection.
The extremely small size of these interconnect elements gives the SX family abundant routing resources and provides excellent protection against design pirating. Reverse engineering is virtually impossible because it is extremely difficult to distinguish between programmed and unprogrammed antifuses, and there is no configuration bitstream to intercept.
Additionally, the interconnect (i.e., the antifuses and metal tracks) have lower capacitance and lower resistance than any other device of similar capacity, leading to the fastest signal propagation in the industry.

Figure 1 •SX Family Interconnect Elements

## Logic Module Design

The SX family architecture is described as a "sea-of-modules" architecture because the entire floor of the device is covered with a grid of logic modules with virtually no chip area lost to interconnect elements or routing. Actel's SX family provides two types of logic modules, the register cell (R-cell) and the combinatorial cell (C-cell).

The R-cell contains a flip-flop featuring asynchronous clear, asynchronous preset, and clock enable (using the S0 and S1 lines) control signals (Figure 2 on page 5). The R-cell registers feature programmable clock polarity selectable on a register-by-register basis. This provides additional flexibility while allowing mapping of synthesized functions into the SX FPGA. The clock source for the R-cell can be chosen from either the hard-wired clock or the routed clock.

The C-cell implements a range of combinatorial functions up to 5 -inputs (Figure 3). Inclusion of the DB input and its associated inverter function dramatically increases the number of combinatorial functions that can be implemented in a single module from 800 options in previous architectures to more than 4,000 in the $S X$ architecture. An example of the improved flexibility
enabled by the inversion capability is the ability to integrate a 3 -input exclusive-OR function into a single C-cell. This facilitates construction of 9 -bit parity-tree functions with 2 ns propagation delays. At the same time, the C-cell structure is extremely synthesis friendly, simplifying the overall design and reducing synthesis time.

Figure 2 - R-Cell

Figure 3 - C-Cell

## Chip Architecture

The SX family's chip architecture provides a unique approach to module organization and chip routing that delivers the best register/logic mix for a wide variety of new and emerging applications.

## Module Organization

Actel has arranged all C-cell and R-cell logic modules into horizontal banks called Clusters. There are two types of Clusters: Type 1 contains two C -cells and one R-cell, while

Type 2 contains one C-cell and two R-cells.
To increase design efficiency and device performance, Actel has further organized these modules into SuperClusters (Figure 4 on page 6). SuperCluster 1 is a two-wide grouping of Type 1 clusters. SuperCluster 2 is a two-wide group containing one Type 1 cluster and one Type 2 cluster. SX devices feature more SuperCluster 1 modules than SuperCluster 2 modules because designers typically require significantly more combinatorial logic than flip-flops.

Type 1 SuperCluster
Type 2 SuperCluster
Figure 4 - Cluster Organization

## Routing Resources

Clusters and SuperClusters can be connected through the use of two innovative local routing resources called FastConnect and DirectConnect, which enable extremely fast and predictable interconnection of modules within Clusters and SuperClusters (Figure 5 and Figure 6 on page 7). This routing architecture also dramatically reduces the number of antifuses required to complete a circuit, ensuring the highest possible performance.
DirectConnect is a horizontal routing resource that provides connections from a C-cell to its neighboring R-cell in a given SuperCluster. DirectConnect uses a hard-wired signal path requiring no programmable interconnection to achieve its fast signal propagation time of less than 0.1 ns .

FastConnect enables horizontal routing between any two logic modules within a given SuperCluster and vertical routing with the SuperCluster immediately below it. Only one programmable connection is used in a FastConnect path, delivering maximum pin-to-pin propagation of 0.4 ns .

In addition to DirectConnect and FastConnect, the architecture makes use of two globally oriented routing resources known as segmented routing and high-drive routing. Actel's segmented routing structure provides a variety of track lengths for extremely fast routing between SuperClusters. The exact combination of track lengths and antifuses within each path is chosen by the 100 percent automatic place and route software to minimize signal propagation delays.
Actel's high-drive routing structure provides three clock networks. The first clock, called HCLK, is hard wired from the HCLK buffer to the clock select MUX in each R-cell. This provides a fast propagation path for the clock signal, enabling the 3.7 ns clock-to-out (pin-to-pin) performance of the SX devices. The hard-wired clock is tuned to provide clock skew as low as 0.25 ns. The remaining two clocks (CLKA, CLKB) are global clocks that can be sourced from external pins or from internal logic signals within the SX device.

## Other Architectural Features

## Technology

Actel's SX family is implemented on a high-voltage twin-well CMOS process using $0.35 \mu$ design rules. The metal-to-metal antifuse is made up of a combination of amorphous silicon
and dielectric material with barrier metals and has a programmed ("on" state) resistance of $25 \Omega$ with capacitance of 1.0 fF for low signal impedance.

Direct Connect

- No antifuses
- 0.1 ns routing delay

Fast Connect

- One antifuse
- 0.4 ns routing delay

Routing Segments

- Typically 2 antifuses
- Max. 5 antifuses

Figure 5 - DirectConnect and FastConnect for Type 1 SuperClusters

## Performance

The combination of architectural features described above enables SX devices to operate with internal clock frequencies exceeding 300 MHz , enabling very fast execution of even complex logic functions. Thus, the SX family is an optimal platform upon which to integrate the functionality previously contained in multiple CPLDs. In addition, designs that previously would have required a gate array to meet performance goals can now be integrated into an SX device with dramatic improvements in cost and time to market. Using timing-driven place and route tools, designers can achieve highly deterministic device performance. With SX devices, designers do not need to use complicated performance-enhancing design techniques such as the use of redundant logic to reduce fanout on critical nets or the instantiation of macros in HDL code to achieve high performance.

## I/O Modules

Each I/O on an SX device can be configured as an input, an output, a tristate output, or a bidirectional pin. Even without the inclusion of dedicated I/O registers, these I/Os, in combination with array registers, can achieve clock-to-out (pad-to-pad) timing as fast as 3.7 ns . I/O cells that have embedded latches and flip-flops require instantiation in HDL code; this is a design complication not encountered in SX FPGAs. Fast pin-to-pin timing ensures that the device will have little trouble interfacing with any other device in the system, which in turn enables parallel design of system components and reduces overall design time.

## Power Requirements

The SX family supports 3.3 V operation and is designed to tolerate 5.0 V inputs. (Table 1). Power consumption is extremely low due to the very short distances signals are required to travel to complete a circuit. Power requirements are further reduced because of the small number of low-resistance antifuses in the path. The antifuse architecture does not require active circuitry to hold a charge (as do SRAM or EPROM), making it the lowest-power architecture on the market.

Table 1 - Supply Voltages

|  | $\mathbf{V}_{\text {CCA }}$ | $\mathbf{v}_{\text {CCI }}$ | $\mathbf{v}_{\text {CCR }}$ | Maximum <br> Input <br> Tolerance | Maximum <br> Output <br> Drive |
| :--- | :---: | :---: | :---: | :---: | :---: |
| A54SX08 |  |  |  |  |  |
| A54SX16 | 3.3 V | 3.3 V | 5.0 V | 5.0 V | 3.3 V |
| A54SX32 |  |  |  |  |  |
|  | 3.3 V | 3.3 V | 3.3 V | 3.3 V | 3.3 V |
| A54SX16-P | 3.3 V | 3.3 V | 5.0 V | 5.0 V | 3.3 V |
|  | 3.3 V | 5.0 V | 5.0 V | 5.0 V | 5.0 V |

Note: A54SX16-P has three different entries because it is capable of both a 3.3 V and a 5 V drive.

## Boundary Scan Testing (BST)

All SX devices are IEEE 1149.1 compliant. SX devices offer superior diagnostic and testing capabilities by providing Boundary Scan Testing (BST) and probing capabilities. These functions are controlled through the special test pins in conjunction with the program fuse. The functionality of each pin is described in Table 2.In the dedicated test mode, TCK, TDI and TDO are dedicated pins and cannot be used as regular I/Os. In flexible mode, TMS should be set HIGH through a pull-up resistor of $10 \mathrm{k} \Omega$. TMS can be pulled LOW to initiate the test sequence.

The program fuse determines whether the device is in dedicated or flexible mode. The default (fuse not blown) is flexible mode.

Table 2 - Boundary Scan Pin Functionality

| Program Fuse Blown <br> (Dedicated Test Mode) | Program Fuse Not Blown <br> (Flexible Mode) |
| :--- | :--- |
| TCK, TDI, TDO are <br> dedicated BST pins | TCK, TDI, TDO are flexible |

| :--- | :--- |
| for TMS |$\quad$| Use a pull-up resistor of 10k |
| :--- |
| $\Omega$ on TMS |

## Development Tool Support

The SX devices are fully supported by Actel's line of FPGA development tools, including the Actel DeskTOP series and Designer Advantage tools. The Actel DeskTOP series is an integrated design environment for PCs that includes design entry, simulation, synthesis, and place and route tools. Designer Advantage, Actel's suite of FPGA development point tools for PCs and Workstations, includes the ACTgen Macro Builder, Designer with DirectTime timing driven place and route and analysis tools, and device programming software.

In addition, the SX devices contain ActionProbe circuitry that provides built-in access to every node in a design, enabling 100-percent real-time observation and analysis of a device's internal logic nodes without design iteration. The probe circuitry is accessed by Silicon Explorer II, an easy-to-use integrated verification and logic analysis tool that can sample data at 100 MHz (asynchronous) or 66 MHz (synchronous). Silicon Explorer II attaches to a PC's standard COM port, turning the PC into a fully functional 18-channel logic analyzer. Silicon Explorer II allows designers to complete the design verification process at their desks and reduces verification time from several hours per cycle to only a few seconds.

## SX Probe Circuit Control Pins

The Silicon Explorer II tool uses the boundary scan ports (TDI, TCK, TMS and TDO) to select the desired nets for verification. The selected internal nets are assigned to the PRA/PRB pins for observation. Figure 7 illustrates the interconnection between Silicon Explorer II and the FPGA to perform in-circuit verification. The TRST pin is equipped with a pull-up resistor. To remove the boundary scan state machine from the reset state during probing, it is
recommended that the TRST pin be left floating.

## Design Considerations

The TDI, TCK, TDO, PRA, and PRB pins should not be used as input or bidirectional ports. Because these pins are active during probing, critical signals input through these pins are not available while probing. In addition, the Security Fuse should not be programmed because doing so disables the Probe Circuitry.

Figure 7 • Probe Setup

### 3.3V/5V Operating Conditions

## Absolute Maximum Ratings ${ }^{1}$

| Symbol | Parameter | Limits | Units |
| :--- | :--- | :---: | :---: |
| $\mathrm{V}_{\mathrm{CCR}}{ }^{2}$ | DC Supply Voltage $^{3}$ | -0.3 to +6.0 | V |
| $\mathrm{~V}_{\mathrm{CCA}}{ }^{2}$ | DC Supply Voltage | -0.3 to +4.0 | V |
| $\mathrm{~V}_{\mathrm{CCI}}{ }^{2}$ | DC Supply Voltage <br> (A54SX08, A54SX16, <br> A54SX32) | -0.3 to +4.0 | V |
| $\mathrm{~V}_{\mathrm{CCI}}{ }^{2}$ | DC Supply Voltage <br> (A54SX16P) | -0.3 to +6.0 | V |
| $\mathrm{~V}_{\mathrm{I}}$ | Input Voltage | -0.5 to +5.5 | V |
| $\mathrm{~V}_{\mathrm{O}}$ | Output Voltage | -0.5 to +3.6 | V |
| $\mathrm{I}_{\mathrm{IO}}$ | I/O Source Sink <br> Current |  | -30 to +5.0 |
| $\mathrm{~T}_{\mathrm{STG}}$ | Storage Temperature | -65 to +150 | mA |

## Notes:

1. Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device Exposure to absolute maximum rated conditions for extended periods may affect device reliability. Device should not be operated outside the Recommended Operating Conditions.
2. $\quad \mathrm{V}_{\mathrm{CCR}}$ in the $\mathrm{A} 54 \mathrm{SX16P}$ must be greater than or equal to $\mathrm{V}_{\mathrm{CCI}}$ during power-up and power-down sequences and during normal operation.
3. Device inputs are normally high impedance and draw extremely low current. However, when input voltage is greater than $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$ or less than GND -0.5 V , theinternal protection diodes will forward-bias and can draw excessive current.

## Recommended Operating Conditions

| Parameter | Commer <br> cial | Industrial | Military | Units |
| :--- | :---: | :---: | :---: | :---: |
| Temperature <br> Range $^{1}$ | 0 to +70 | -40 to +85 | -55 to +125 | ${ }^{\circ} \mathrm{C}$ |
| 3.3 V Power <br> Supply <br> Tolerance | $\pm 10$ | $\pm 10$ | $\pm 10$ | $\% \mathrm{~V}_{\mathrm{C}}$ |
| 5.0V Power <br> Supply <br> Tolerance | $\pm 5$ | $\pm 10$ | $\pm 10$ | $\% \mathrm{~V}_{\mathrm{C}}$ |
| Note: |  |  | C |  |

1. Ambient temperature $\left(T_{A}\right)$ is used for commercial and industrial; case temperature $\left(T_{C}\right)$ is used for military.

## Notes:

1. Input leakage currents includehi-Z output leakage for all bi-directional buffers with tri-stateoutputs.
2. Signals without pull-up resistors must have 3 mA low output current. Signals requiring pull up must have 6 mA ; the latter include, FRAME\#, IRDY\#, TRDY\#, DEVSEL\#, STOP\#, SERR\#, PERR\#, LOCK\#, and, when used AD[63::32], C/BE[7::4]\#, PAR64, REQ64\#, and ACK64\#.
3. Absolutemaximum pin capacitancefor a PCl input is 10 pF (except for CLK).
4. Lower capacitanceon this input-only pin allows for non-resistive coupling to $A D[x x]$.

## A54SX16P AC Specifications for (PCI Operation)

| Symbol | Parameter | Condition | Min. | Max. | Units |
| :---: | :---: | :---: | :---: | :---: | :---: |
| ${ }^{\mathrm{I}} \mathrm{OH}(\mathrm{AC})$ | Switching Current High | $0<\mathrm{V}_{\text {OUT }} \leq 1.4{ }^{1}$ | -44 |  | mA |
|  |  | $1.4 \leq \mathrm{V}_{\text {OUT }}<2.4^{1,2}$ | $-44+\left(\mathrm{V}_{\text {OUT }}-1.4\right) / 0.024$ |  | mA |
|  |  | $3.1<\mathrm{V}_{\text {OUT }}<\mathrm{V}_{\text {CC }}{ }^{1,3}$ |  | Equation A: on page 13 |  |
|  | (Test Point) | $\mathrm{V}_{\text {OUT }}=3.1^{3}$ |  | -142 | mA |
| $\mathrm{I}_{\text {OL(AC) }}$ | Switching Current High | $\mathrm{V}_{\text {OUT }} \geq 2.2^{1}$ | 95 |  | mA |
|  |  | $2.2>\mathrm{V}_{\text {OUT }}>0.55^{1}$ | $\mathrm{V}_{\text {OUT }} / 0.023$ |  |  |
|  |  | $0.71>\mathrm{V}_{\text {OUT }}>0^{1,3}$ |  | Equation B : on page 13 | mA |
|  | (Test Point) | $\mathrm{V}_{\text {OUT }}=0.71^{3}$ |  | 206 | mA |
| $\mathrm{I}_{\mathrm{CL}}$ | Low Clamp Current | $-5<\mathrm{V}_{\text {IN }} \leq-1$ | $-25+\left(\mathrm{V}_{\text {IN }}+1\right) / 0.015$ |  | mA |
| slew $_{\text {R }}$ | Output Rise Slew Rate | 0.4 V to 2.4 V load $^{4}$ | 1 | 5 | V/ns |
| slew $_{\text {F }}$ | Output Fall Slew Rate | 2.4 V to 0.4V load $^{4}$ | 1 | 5 | V/ns |

Notes:

1. Refer to theV/I curves in Figure 8. Switching current characteristics for REQ\#and GNT\#are permitted to be onehalf of that specified here; i.e., half size output drivers may be used on these signals. This specification does not apply to CLK and RST\#which are system outputs. "Switching Current High" specification are not relevant to SERR\#, INTA\#, INTB\#, INTC\#, and INTD\#which areopen drain outputs.
2. Note that this segment of the minimum current curve is drawn from the $A C$ drive point directly to the $D C$ drive point rather than toward thevoltage rail (as is donein thepull-down curve). This differenceis intended to allow for an optional N -channel pull-up.
3. Maximum current requirements must be met as drivers pull beyond the last step voltage. Equations defining these maximums (A and B) are provided with the respective diagrams in Figure8. The equation defined maxima should be met by design. In order to facilitate component testing, a maximum current test point is defined for each side of theoutput driver.
4. This parameter is to be interpreted as the cumulative edge rateacr oss the specified range, rather than the instantaneous rateat any point within the transition range. The specified load (diagram below) is optional; i.e., the designer may elect to mect this parameter with an unloaded output per revision 2.0 of the PCI Local Bus Specification. However, adherence to both maximum and minimum parameters is now required (the maximum is no longer simply a guideline). Since adherence to the maximum slew rate was not required prior to revision 2.1 of the specification, there may be components in the market for some time that have faster edge rates; therefore, motherboard designers must bear in mind that rise and fall times faster than this specification could occur, and should ensure that signal integrity modeling accounts for this. Riseslew rate does not apply to open drain outputs.

Figure 8 shows the $5.0 \mathrm{~V} \mathrm{PCI} \mathrm{V} / \mathrm{I}$ curve and the minimum and maximum PCI drive characteristics of the A54SX16P family.

Figure 8 - 5.0V PCI Curvefor A54SX16P Family

Equation A :

$$
\begin{gathered}
I_{\text {OH }}=11.9 *\left(V_{\text {OUT }}-5.25\right) *\left(V_{\text {OUT }}+2.45\right) \\
\quad \text { for } V_{\text {CC }}>V_{\text {OUT }}>3.1 V
\end{gathered}
$$

Equation B:

$$
\begin{gathered}
\mathrm{I}_{\text {OL }}=78.5 * \mathrm{~V}_{\text {OUT }} *\left(4.4-\mathrm{V}_{\text {OUT }}\right) \\
\\
\text { for } \mathrm{OV}<\mathrm{V}_{\text {OUT }}<0.71 \mathrm{~V}
\end{gathered}
$$

## A54SX16P DC Specifications (3.3V PCI Operation)

| Symbol | Parameter | Condition | Min. | Max. | Units |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{\text {CCA }}$ | Supply Voltage for Array |  | 3.0 | 3.6 | V |
| $\mathrm{V}_{\text {CCR }}$ | Supply Voltage required for Internal Biasing |  | 3.0 | 3.6 | V |
| $\mathrm{V}_{\text {CCI }}$ | Supply Voltage for IOs |  | 3.0 | 3.6 | V |
| $\mathrm{V}_{\mathrm{IH}}$ | Input High Voltage |  | $0.5 \mathrm{~V}_{\mathrm{CC}}$ | $\mathrm{V}_{\mathrm{CC}}+0.5$ | V |
| $\mathrm{V}_{\text {IL }}$ | Input Low Voltage |  | -0.5 | $0.3 \mathrm{~V}_{\text {CC }}$ | V |
| IIPU | Input Pull-up Voltage ${ }^{\text {¹ }}$ |  | $0.7 \mathrm{~V}_{\mathrm{CC}}$ |  | V |
| ILL | Input Leakage Current ${ }^{2}$ | $0<\mathrm{V}_{\text {IN }}<\mathrm{V}_{\mathrm{CC}}$ |  | $\pm 10$ | $\mu \mathrm{A}$ |
| $\mathrm{V}_{\mathrm{OH}}$ | Output High Voltage | IOUT $=-500 \mu \mathrm{~A}$ | $0.9 \mathrm{~V}_{\text {CC }}$ |  | V |
| $\mathrm{V}_{\text {OL }}$ | Output Low Voltage | $\mathrm{I}_{\text {OUT }}=1500 \mu \mathrm{~A}$ |  | $0.1 \mathrm{~V}_{\mathrm{CC}}$ | V |
| $\mathrm{C}_{\text {IN }}$ | Input Pin Capacitance ${ }^{3}$ |  |  | 10 | pF |
| $\mathrm{C}_{\text {CLK }}$ | CLK Pin Capacitance |  | 5 | 12 | pF |
| $\mathrm{C}_{\text {IDSEL }}$ | IDSEL Pin Capacitance ${ }^{4}$ |  |  | 8 | pF |

Notes:

1. This specification should be guaranteed by design. It is the minimum voltage to which pull-up resistors are calculated to pull a floated network. Applications sensitive to static power utilization should assure that the input buffer is conducting minimum current at this input voltage.
2. Input leakagecurrents includehi-Z output leakage for all bi-directional buffers with tri-state outputs.
3. Absolutemaximum pin capacitance for a PCl input is 10 pF (except for CLK).
4. Lower capacitance on this input-only pin allows for non-resistive coupling to $A D[x x]$.

A 54SX16P AC Specifications (3.3V PCI Operation)

| Symbol | Parameter | Condition | Min. | Max. | Units |

## Notes:

1. Refer to the V/I curves in Figure9. Switching current characteristics for REQ\#and GNT\#are per mitted to be onehalf of that specified here; i.e., half size output drivers may be used on these signals. This specification does not apply to CLK and RST\#which are system outputs. "Switching Current High" specification arenot relevant to SERR\#, INTA\#, INTB\#, INTC\#, and INTD\#which areopen drain outputs.
2. Maximum current requirements must be met as drivers pull beyond the last step voltage. Equations defining these maximums ( $C$ and $D$ ) are provided with the respective diagrams in Figure9. The equation defined maxima should be met by design. In order to facilitate component testing, a maximum current test point is defi ned for each side of the output driver.
3. This parameter is to be interpreted as the cumulative edge rate across the specified range, rather than the instantaneous rate at any point within the transition range. The specified load (diagram below) is optional; i.e., the designer may elect to meet this parameter with an unloaded output per the latest revision of the PCl Local Bus Specification. However, adherence to both maximum and minimum parameters is required (themaximum is no longer simply a guideline). Rise slew rate does not apply to open drain outputs.

Figure 9 shows the $3.3 \mathrm{~V} P \mathrm{PCI} \mathrm{V} / \mathrm{c}$ curve and the minimum and maximum PCl drive characteristics of the A54SX16P family.

Figure 9 • 3.3V PCI Curvefor A54SX16P Family

Equation C :

$$
\begin{gathered}
\mathrm{I}_{\text {OH }}=\left(98.0 / \mathrm{V}_{\mathrm{CC}}\right) *\left(\mathrm{~V}_{\text {OUT }}-\mathrm{V}_{\mathrm{CC}}\right) *\left(\mathrm{~V}_{\text {OUT }}+0.4 \mathrm{~V}_{\text {CC }}\right) \\
\text { for } \mathrm{V}_{\mathrm{CC}}>\mathrm{V}_{\text {OUT }}>0.7 \mathrm{~V}_{\mathrm{CC}}
\end{gathered}
$$

## Equation D:

$$
\begin{aligned}
I_{O L}= & \left(256 / V_{C C}\right) * V_{\text {OUT }} *\left(V_{C C}-V_{\text {OUT }}\right) \\
& \text { for } 0 \mathrm{~V}<V_{\text {OUT }}<0.18 V_{\text {CC }}
\end{aligned}
$$

Power-Up Sequencing

## Evaluating Power in 54SX Devices

A critical element of system reliability is the ability of electronic devices to safely dissipate the heat generated during operation. The thermal characteristics of a circuit depend on the device and package used, the operating temperature, the operating current, and the system's ability to dissipate heat.

You should complete a power evaluation early in the design process to help identify potential heat-related problems in the system and to prevent the system from exceeding the device's maximum allowed junction temperature.
The actual power dissipated by most applications is significantly lower than the power the package can dissipate. However, a thermal analysis should be performed for all projects. To perform a power evaluation, follow these steps:

- Estimate the power consumption of the application.
- Calculate the maximum power allowed for the device and package.
- Compare the estimated power and maximum power values.

## Estimating Power Consumption

The total power dissipation for the 54SX family is the sum of the DC power dissipation and the AC power dissipation. Use Equation 1 to calculate the estimated power consumption of your application.
$P_{\text {Total }}=P_{D C}+P_{A C}$

## DC Power Dissipation

The power due to standby current is typically a small component of the overall power. The Standby power is shown below for commercial, worst case conditions $\left(70^{\circ} \mathrm{C}\right)$.

## Table 3 •

| ICC | V CC | Power |
| :--- | :--- | :--- |
| 4 mA | 3.6 V | 14.4 mW |

The DC power dissipation is defined in Equation 2 as follows:
$P_{D C}=\left(I_{\text {standby }}\right) * V_{C C A}+\left(I_{\text {standby }}\right) * V_{C C R}+$
$\left(\mathrm{I}_{\text {standby }}\right) * \mathrm{~V}_{\mathrm{CCI}}+\mathrm{x}^{*} \mathrm{~V}_{\mathrm{OL}} \mathrm{I}_{\mathrm{OL}}+\mathrm{y}^{*}\left(\mathrm{~V}_{\mathrm{CCI}}-\mathrm{V}_{\mathrm{OH}}\right) * \mathrm{~V}_{\mathrm{OH}}$

## AC Power Dissipation

The power dissipation of the 54SX Family is usually dominated by the dynamic power dissipation. Dynamic power dissipation is a function of frequency, equivalent capacitance and power supply voltage. The AC power
dissipation is defined as follows:

```
\(P_{\text {AC }}=P_{\text {Module }}+P_{\text {RCLKA Net }}+P_{\text {RCLKB Net }}+P_{\text {HCLK Net }}+\)
\(P_{\text {Output Buffer }}+P_{\text {Input Buffer }}\)
\(P_{A C}=V_{C C A}{ }^{2} *\left[\left(m * C_{E Q M} * f_{m}\right)_{\text {Module }}+\right.\)
\(\left(n * C_{E Q Q} * f_{n}\right)_{\text {Input Buffer }}+\left(p^{*}\left(C_{E Q O}+C_{L}\right) * f_{p}\right)_{\text {Output Buffer }}+\)
\(\left(0.5 *\left(q_{1} * C_{E Q C R} * f_{q 1}\right)+\left(r_{1} * f_{q 1}\right)\right)_{R C L K A}+\)
\(\left(0.5 *\left(q_{2} * C_{E Q C R} * f_{q 2}\right)+\left(r_{2} * f_{q 2}\right)\right)_{\text {RCLKB }}+\)
\(\left.\left(0.5 *\left(\mathrm{~s}_{1} * \mathrm{C}_{\mathrm{EQHV}} * \mathrm{f}_{\mathrm{S} 1}\right)+\left(\mathrm{C}_{\mathrm{EQHF}} * \mathrm{f}_{\mathrm{S} 1}\right)\right)_{\mathrm{HCLK}}\right]\)

\section*{Guidelines for Calculating Power Consumption}

The following guidelines are meant to represent worst-case scenarios so that they can be generally used to predict the upper limits of power dissipation. These guidelines are as follow:
\begin{tabular}{|c|c|}
\hline Logic Modules (m) & = \(20 \%\) of modules \\
\hline Inputs Switching ( n ) & = \#inputs/4 \\
\hline Outputs Switching (p) & = \#output/4 \\
\hline First Routed Array Clock Loads ( \(\mathrm{q}_{1}\) ) & \[
\begin{aligned}
& =20 \% \text { of register } \\
& \text { cells }
\end{aligned}
\] \\
\hline Second Routed Array Clock Loads & \(=20 \%\) of register cells \\
\hline Load Capacitance ( \(\mathrm{C}_{\mathrm{L}}\) ) & \(=35 \mathrm{pF}\) \\
\hline Average Logic Module Switching ( \(f_{m}\) ) & \[
e=f / 10
\] \\
\hline Average Input Switching Rate ( \(\mathrm{f}_{\mathrm{n}}\) ) & = f/5 \\
\hline Average Output Switching Rate ( \(\mathrm{f}_{\mathrm{p}}\) ) & = f/10 \\
\hline Average First Routed Array Clock R ( \(\mathrm{f}_{\mathrm{q} 1}\) ) & \[
e=f / 2
\] \\
\hline Average Second Routed Array Cl Rate ( \(\mathrm{f}_{\mathrm{q} 2}\) ) & \[
=f / 2
\] \\
\hline Average Dedicated Array Clock Rate ( \(\mathrm{f}_{\mathrm{s} 1}\) ) & \\
\hline Dedicated Clock Array clock loads (s & \(=20 \%\) of regular modules \\
\hline
\end{tabular}

\section*{Sample Power Calculation}

One of the designs used to characterize the A54SX family was a 528 bit serial in serial out shift register. The design utilized \(100 \%\) of the dedicated flip-flops of an A54SX16P device. A pattern of 0101... was clocked into the device at frequencies ranging from 1 MHz to 200 MHz . Shifting in a series of 0101 ... caused \(50 \%\) of the flip-flops to toggle from low to high at every clock cycle.
Follow the steps below to estimate power consumption. The values provided for the sample calculation below are for the shift register design above. This method for estimating power consumption is conservative and the actual power consumption of your design may be less than the estimated power consumption.
The total power dissipation for the 54SX family is the sum of the AC power dissipation and the DC power dissipation.
\(P_{\text {Total }}=P_{A C}\) (dynamic power) \(+P_{D C}\) (static power)

\section*{AC Power Dissipation}
\[
\begin{align*}
& P_{\text {AC }}=P_{\text {Module }}+P_{\text {RCLKA Net }}+P_{\text {RCLKB Net }}+P_{\text {HCLK Net }}+ \\

n*f * \(\mathrm{C}_{\text {Eal }} 0.00013\)
\(p^{*} f_{p}{ }^{*}\left(C_{E Q O}+C_{L}\right)\)
\(0.5 *\left(q_{1}{ }^{*} C_{E Q C R}{ }^{* f_{1}}\right)+\left(r_{1}{ }^{*} f_{q_{1}}\right)\)
\(0.5 *\left(q_{2}{ }^{*} C_{E Q C R}{ }^{* f} q_{2}\right)+\left(r_{2}{ }^{* f} \mathrm{f}_{2}\right)\)
\(0.5 *\left(\mathrm{~s}_{1} * \mathrm{C}_{\text {EQHV }} * \mathrm{f}_{\mathrm{S} 1}\right)+\left(\mathrm{C}_{\text {EQHF }} * \mathrm{f}_{\mathrm{S} 1}\right)\)
\(P_{A C}=1.461 \mathrm{~W}\)

\section*{Step \#3: Calculate DC Power Dissipation}

\section*{DC Power Dissipation}
\(P_{D C}=\left(I_{\text {standby }}\right) * V_{C C A}+\left(I_{\text {standby }}\right) * V_{C C R}+\left(I_{\text {standby }}\right) * V_{C C I}+\) \(X * V_{O L}{ }^{*} \mathrm{IOL}_{\mathrm{OL}}+\mathrm{Y}^{*}\left(\mathrm{~V}_{\mathrm{CCI}}-\mathrm{V}_{\mathrm{OH}}\right) * \mathrm{~V}_{\mathrm{OH}}\)
For a rough estimate of DC Power Dissipation, only use \(P_{D C}=\left(I_{\text {standby }}\right) * V_{C C A}\). The rest of the formula provides a very small number that can be considered negligible.
\(P_{D C}=\left(I_{\text {standby }}\right) * V_{C C A}\)
\(P_{D C}=.55 \mathrm{~mA} * 3.3 \mathrm{~V}\)
\(P_{D C}=0.001815 \mathrm{~W}\)
Step \#4: Calculate Total Power Consumption
\(P_{\text {Total }}=P_{A C}+P_{D C}\)
\(P_{\text {Total }}=1.461+0.001815\)
\(\mathrm{P}_{\text {Total }}=1.4628 \mathrm{~W}\)

\section*{Step \#5: Compare E stimated Power Consumption against Characterized Power Consumption}

The estimated total power consumption for this design is 1.46 W . The characterized power consumption for this design at 200 MHz is 1.0164 W . Figure 10 shows the characterized power dissipation numbers for the shift register design using frequencies ranging from 1 MHz to 200 MHz .

Figure 10 • Power Dissipation

Junction Temperature ( \(\mathrm{T}_{\mathrm{J}}\) )
The temperature that you select in Designer Series software is the junction temperature, not ambient temperature. This is an important distinction because the heat generated from dynamic power consumption is usually hotter than the ambient temperature. Use the equation below to calculate junction temperature.
\[
\text { Junction Temperature }=\Delta \mathrm{T}+\mathrm{T}_{\mathrm{a}}
\]

Where:
\(T_{a}=\) Ambient Temperature
\(\Delta \mathrm{T}=\) Temperature gradient between junction (silicon) and ambient
\(\Delta \mathrm{T}=\theta_{\mathrm{ja}} * \mathrm{P}\)

P = Power calculated from Estimating Power Consumption section
\(\theta_{\mathrm{ja}}=\) Junction to ambient of package. \(\theta_{\mathrm{ja}}\) numbers are located in Package Thermal Characteristics section.

\section*{Package Thermal Characteristics}

The device junction to case thermal characteristic is \(\theta_{\mathrm{jc}}\), and the junction to ambient air characteristic is \(\theta_{\mathrm{ja}}\). The thermal characteristics for \(\theta_{\mathrm{ja}}\) are shown with two different air flow rates.
The maximum junction temperature is \(150^{\circ} \mathrm{C}\).
A sample calculation of the absolute maximum power dissipation allowed for a TQFP 176-pin package at commercial temperature and still air is as follows:

Maximum Power Allowed \(=\frac{\text { Max. junction temp. }\left({ }^{\circ} \mathrm{C}\right)-\text { Max. ambient temp. }\left({ }^{\circ} \mathrm{C}\right)}{\theta_{j a}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)}=\frac{150^{\circ} \mathrm{C}-70^{\circ} \mathrm{C}}{28^{\circ} \mathrm{C} / \mathrm{W}}=2.86 \mathrm{~W}\)
\begin{tabular}{|lccccc|}

C-Cell Delays

\section*{Register Cell Timing Characteristics}

\section*{Flip-Flops}

\section*{Timing Characteristics}

Timing characteristics for 54SX devices fall into three categories: family-dependent, device-dependent, and design-dependent. The input and output buffer characteristics are common to all 54SX family members. Internal routing delays are device dependent. Design dependency means actual delays are not determined until after placement and routing of the user's design is complete. Delay values may then be determined by using the DirectTime Analyzer utility or performing simulation with post-layout delays.

\section*{Critical Nets and Typical Nets}

Propagation delays are expressed only for typical nets, which are used for initial design performance evaluation. Critical net delays can then be applied to the most time-critical paths. Critical nets are determined by net property assignment prior to placement and routing. Up to \(6 \%\) of the nets in a design may be designated as critical, while \(90 \%\) of the nets in a design are typical.

\section*{Long Tracks}

Some nets in the design use long tracks. Long tracks are special routing resources that span multiple rows, columns, or modules. Long tracks employ three and sometimes five antifuse connections. This increases capacitance and resistance, resulting in longer net delays for macros connected to long tracks. Typically up to \(6 \%\) of nets in a fully utilized device require long tracks. Long tracks contribute approximately 4 ns to 8.4 ns delay. This additional delay is represented statistically in higher fanout ( \(F O=24\) ) routing delays in the data sheet specifications section.

\section*{Timing Derating}

54SX devices are manufactured in a CMOS process. Therefore, device performance varies according to temperature, voltage, and process variations. Minimum timing parameters reflect maximum operating voltage, minimum operating temperature, and best-case processing. Maximum timing parameters reflect minimum operating voltage, maximum operating temperature, and worst-case processing.

Temperature and Voltage Derating Factors
(Normalized to Worst-Case Commercial, \(\mathbf{T}_{\mathrm{J}}=\mathbf{7 0}{ }^{\circ} \mathrm{C}, \mathrm{V}_{\mathrm{CCA}}=\mathbf{3 . 0 V}\) )
\begin{tabular}{|c|ccccc|c|c|}
\hline & \multicolumn{7}{|c|}{ Junction Temperature ( \(\mathbf{T}_{\mathbf{J}}\) ) } \\
\cline { 2 - 9 } \(\mathbf{V}_{\text {CCA }}\) & \(\mathbf{- 5 5}\) & \(\mathbf{- 4 0}\) & \(\mathbf{0}\) & \(\mathbf{2 5}\) & \(\mathbf{7 0}\) & \(\mathbf{8 5}\) & \(\mathbf{1 2 5}\) \\
\hline \(\mathbf{3 . 0}\) & 0.75 & 0.78 & 0.87 & 0.89 & 1.00 & 1.04 & 1.16 \\
\(\mathbf{3 . 3}\) & 0.70 & 0.73 & 0.82 & 0.83 & 0.93 & 0.97 & 1.08 \\
\hline \(\mathbf{3 . 6}\) & 0.66 & 0.69 & 0.77 & 0.78 & 0.87 & 0.92 & 1.02 \\
\hline
\end{tabular}

\section*{A54SX08 Timing Characteristics}
(Worst-Case Commercial Conditions, \(\mathrm{V}_{\mathrm{CCR}}=4.75 \mathrm{~V}, \mathrm{~V}_{\mathrm{CCA}}, \mathrm{V}_{\mathrm{CCI}}=3.0 \mathrm{~V}, \mathrm{~T}_{\mathrm{J}}=70^{\circ} \mathrm{C}\) )

\section*{Notes:}
1. For dual-modulemacros, use \(t_{P D}+t_{R D 1}+t_{P D n}, t_{R C O}+t_{R D 1}+t_{P D n}\) or \(t_{P D 1}+t_{R D 1}+t_{S U D}\), whichever is appropriate.
2. Routing delays are for typical designs across worst-case operating conditions. These parameters should be used for estimating device performance. Post-route timing analysis or simulation is required to determine actual worst-case performance. Post-route timing is based on actual routing delay measurements performed on thedevice prior to shipment.

\end{tabular}

\section*{Note:}
1. Delays based on \(35 p F\) loading, except \(t_{\text {ENZL }}\) and \(t_{E N Z H}\). For \(t_{E N Z L}\) and \(t_{\text {ENZH }}\) the loading is \(5 p F\).

\section*{Pin Description}

\section*{CLKA/B Clock A and B}

These pins are \(3.3 \mathrm{~V} / 5.0 \mathrm{~V}\) PCI/TTL clock inputs for clock distribution networks. The clock input is buffered prior to clocking the R-cells. If not used, this pin must be set LOW or HIGH on the board. It must not be left floating. (For A54SX72A, these clocks can be configured as bidirectional.)

\section*{GND}

\section*{Ground}

LOW supply voltage.

\section*{HCLK Dedicated (Hard-wired) Array Clock}

This pin is the \(3.3 \mathrm{~V} / 5.0 \mathrm{~V} \mathrm{PCI} / \mathrm{TTL}\) clock input for sequential modules. This input is directly wired to each R-cell and offers clock speeds independent of the number of R-cells being driven. If not used, this pin must be set LOW or HIGH on the board. It must not be left floating.

\section*{I/O Input/Output}

The I/O pin functions as an input, output, tristate, or bidirectional buffer. Based on certain configurations, input and output levels are compatible with standard TTL, LVTTL, 3.3 V PCI or 5.0 V PCI specifications. Unused I/O pins are automatically tristated by the Designer Series software.

\section*{NC}

No Connection
This pin is not connected to circuitry within the device.

\section*{PRA, I/O Probe A}

The Probe A pin is used to output data from any user-defined design node within the device. This independent diagnostic pin can be used in conjunction with the Probe B pin to allow real-time diagnostic output of any signal path within the device. The Probe A pin can be used as a user-defined I/O when verification has been completed. The pin's probe capabilities can be permanently disabled to protect programmed design confidentiality.

\section*{PRB, I/O Probe B}

The Probe B pin is used to output data from any node within the device. This diagnostic pin can be used in conjunction with the Probe A pin to allow real-time diagnostic output of any signal path within the device. The Probe B pin can be used as a user-defined I/O when verification has been completed. The pin's probe capabilities can be permanently disabled to protect programmed design confidentiality.

\section*{TCK Test Clock}

Test clock input for diagnostic probe and device programming. In flexible mode, TCK becomes active when the TMS pin is set LOW ( refer to Table 2 on page 8). This pin functions as an I/O when the boundary scan state machine reaches the "logic reset" state.

\section*{TDI Test Data Input}

Serial input for boundary scan testing and diagnostic probe. In flexible mode, TDI is active when the TMS pin is set LOW (refer to Table 2 on page 8). This pin functions as an I/O when the boundary scan state machine reaches the "logic reset" state.

\section*{TDO Test Data Output}

Serial output for boundary scan testing. In flexible mode, TDO is active when the TMS pin is set LOW (refer to Table 2 on page 8). This pin functions as an I/O when the boundary scan state machine reaches the "logic reset" state.

TMS

\section*{Test Mode Select}

The TMS pin controls the use of the IEEE 1149.1 Boundary Scan pins (TCK, TDI, TDO). In flexible mode when the TMS pin is set LOW, the TCK, TDI, and TDO pins are boundary scan pins (refer to Table 2 on page 8). Once the boundary scan pins are in test mode, they will remain in that mode until the internal boundary scan state machine reaches the "logic reset" state. At this point, the boundary scan pins will be released and will function as regular I/O pins. The "logic reset" state is reached 5 TCK cycles after the TMS pin is set HIGH. In dedicated test mode, TMS functions as specified in the IEEE 1149.1 specifications.

\section*{\(\mathbf{V}_{\text {cci }} \quad\) Supply Voltage}

Supply voltage for I/Os. See Table 1 on page 8.

\section*{\(\mathbf{V}_{\text {cca }} \quad\) Supply Voltage}

Supply voltage for Array. See Table 1 on page 8.

\section*{\(\mathbf{V}_{\text {CCR }} \quad\) Supply Voltage}

Supply voltage for input tolerance (required for internal biasing) See Table 1 on page 8.

\section*{List of Changes}

The following table lists critical changes that were made in the current version of the document.
\begin{tabular}{|l|l|l|}
\hline Previous version & Changes in current version (v3.1) & Page \\
\hline \multirow{2}{*}{ v3.0.1 } & \begin{tabular}{l} 
The storage temperature in the "Absolute Maximum Ratings"" table on page 10 was \\
updated.
\end{tabular} & page 10 \\
\cline { 2 - 3 } & Table 1 on page 8 was updated. & page 8 \\
\hline
\end{tabular}

\section*{Datasheet Categories}

In order to provide the latest information to designers, some datasheets are published before data has been fully characterized. Datasheets are designated as "Product Brief," "Advanced," "Production." The definition of these categories are as follows:

\section*{Product Brief}

The product brief is a modified version of an advanced datasheet containing general product information. This brief summarizes specific device and family information for unreleased products.

\section*{Advanced}

This datasheet version contains initial estimated information based on simulation, other products, devices, or speed grades. This information can be used as estimates but not for production.

\section*{Unmarked (production)}

This datasheet version contains information that is considered to be final.
