MC68HC11A1
MC68HC11A0**Technical Summary**
8-Bit Microcontrollers**Introduction**

The MC68HC11A8, MC68HC11A1, and MC68HC11A0 high-performance microcontroller units (MCUs) are based on the M68HC11 Family. These high speed, low power consumption chips have multiplexed buses and a fully static design. The chips can operate at frequencies from 3 MHz to dc. The three MCUs are created from the same masks; the only differences are the value stored in the CONFIG register, and whether or not the ROM or EEPROM is tested and guaranteed.

For detailed information about specific characteristics of these MCUs, refer to the *M68HC11 Reference Manual*, document number M68HC11 RM/AD.

Features

- M68HC11 CPU
- Power Saving STOP and WAIT Modes
- 8 KBytes ROM
- 512 Bytes of On-Chip EEPROM
- 256 Bytes of On-Chip RAM (All Saved During Standby)
- 16-Bit Timer System
 - 3 Input Capture Channels
 - 5 Output Compare Channels
- 8-Bit Pulse Accumulator
- Real-Time Interrupt Circuit
- Computer Operating Properly (COP) Watchdog System
- Synchronous Serial Peripheral Interface (SPI)
- Asynchronous Nonreturn to Zero (NRZ) Serial Communications Interface (SCI)
- 8-Channel, 8-Bit Analog-to-Digital (A/D) Converter
- 38 General-Purpose Input/Output (I/O) Pins
 - 15 Bidirectional I/O Pins
 - 11 Input-Only Pins and 12 Output-Only Pins (Eight Output-Only Pins in 48-Pin Package)
- Available in 48-Pin Dual In-Line Package (DIP) or 52-Pin Plastic Leaded Chip Carrier (PLCC)

Operating Modes and Memory Maps

In single-chip operating mode, the MC68HC11A8 is a monolithic microcontroller without external address or data buses.

In expanded multiplexed operating mode, the MCU can access a 64 Kbyte address space. The space includes the same on-chip memory addresses used for single-chip mode plus external peripheral and memory devices. The expansion bus is made up of ports B and C and control signals AS and $\overline{R/W}$. The address, $\overline{R/W}$, and AS signals are active and valid for all bus cycles including accesses to internal memory locations. The following figure illustrates a recommended method of demultiplexing low-order addresses from data at port C.

Address/Data Demultiplexing

Special bootstrap mode allows special purpose programs to be entered into internal RAM. The bootloader program uses the SCI to read a 256-byte program into on-chip RAM at \$0000 through \$00FF. After receiving the character for address \$00FF, control passes to the loaded program at \$0000.

Special test mode is used primarily for factory testing.

Freescale Semiconductor, Inc.

Memory Maps

Memory locations are the same for expanded multiplexed and single-chip modes. The on-board 256-byte RAM is initially located at \$0000 after reset. The 64-byte register block originates at \$1000 after reset. RAM and/or the register block can be placed at any other 4K boundary (\$x000) after reset by writing an appropriate value to the INIT register. The 512-byte EEPROM is located at \$B600 through \$B7FF after reset if it is enabled. The 8 Kbyte ROM is located at \$E000 through \$FFFF if it is enabled.

Hardware priority is built into the memory remapping. Registers have priority over RAM, and RAM has priority over ROM. The higher priority resource covers the lower, making the underlying locations inaccessible.

In special bootstrap mode, a bootloader ROM is enabled at locations \$BF40 through \$BFFF.

In special test and special bootstrap modes, reset and interrupt vectors are located at \$BFC0 through \$BFFF.

Note

The bits of this register are implemented with EEPROM cells. Programming and erasing follow normal EEPROM procedures. The erased state of CONFIG is \$0F. A new value is not readable until after a subsequent reset sequence. CONFIG can only be programmed or erased in special modes.

NOSEC — EEPROM Security Disable
Refer to **Electrically Erasable Programmable Read-Only Memory (EEPROM)**.

NOCOP — COP System Disable
Refer to **Resets and Interrupts**.

ROMON — ROM Enable
In single-chip mode, ROMON is forced to one out of reset.
0 = 8K ROM removed from the memory map
1 = 8K ROM present in the memory map

EEON — EEPROM Enable
0 = EEPROM is removed from the memory map
1 = EEPROM is present in the memory map

Resets and Interrupts

The MC68HC11A8 has 3 reset vectors and 18 interrupt vectors. The reset vectors are as follows:

- $\overline{\text{RESET}}$, or Power-On
- COP Clock Monitor Fail
- COP Failure

The 8 interrupt vectors service 23 interrupt sources (3 non-maskable, 20 maskable). The 3 non-maskable interrupt vectors are as follows:

- Illegal Opcode Trap
- Software Interrupt
- XIRQ Pin (Pseudo Non-Maskable Interrupt)

The 20 maskable interrupt sources are subject to masking by a global interrupt mask, the I bit in the condition code register (CCR). In addition to the global I bit, all of these sources except the external interrupt ($\overline{\text{IRQ}}$) pin are controlled by local enable bits in control registers. Most interrupt sources in the M68HC11 have separate interrupt vectors. For this reason, there is usually no need for software to poll control registers to determine the cause of an interrupt. The maskable interrupt sources respond to a fixed priority relationship, except that any one source can be dynamically elevated to the highest priority position of any maskable source. Refer to the table of interrupt and reset vector assignments.

On-chip peripheral systems generate maskable interrupts that are recognized only if the I bit in the CCR is clear. Maskable interrupts are prioritized according to a default arrangement, but any one source can be elevated to the highest maskable priority position by the HPRIO register. The HPRIO register can be written at any time, provided the I bit in the CCR is set.

For some interrupt sources, such as the parallel I/O and SCI interrupts, the flags are automatically cleared during the course of responding to the interrupt requests. For example, the RDRF flag in the SCI system is cleared by the automatic clearing mechanism, which consists of a read of the SCI status register while RDRF is set, followed by a read of the SCI data register. The normal response to an RDRF interrupt request is to read the SCI status register to check for receive errors, then to read the received data from the SCI data register. These two steps satisfy the automatic clearing mechanism without requiring any special instructions.

The real-time interrupt (RTI) function generates hardware interrupts at a fixed periodic rate. These hardware interrupts provide a time reference signal for routines that measure real time. The routine notes the number of times a particular interrupt has occurred and multiplies that number by the predetermined subroutine execution time.

There are four RTI signal rates available in the MC68HC11A8. The MCU oscillator frequency and the value of two software-accessible control bits, RTR1 and RTR0, in the pulse accumulator control register (PACTL) determine these signal rates. Refer to **Main Timer** for more information about PACTL.

RESET:	0	0	0	0	—	—	—	—

NOTE

The bits of this register are implemented with EEPROM cells. Programming and erasing follow normal EEPROM procedures. The erased state of CONFIG is \$0F. A new value is not readable until after a subsequent reset sequence. CONFIG can only be programmed or erased in special modes.

NOSEC — EEPROM Security Disable

Refer to **Electrically Erasable Programmable Read-Only Memory (EEPROM)**.

NOCOP — COP system disable

- 0 = COP enabled (forces reset on timeout)
- 1 = COP disabled (does not force reset on timeout)

ROMON — ROM Enable

Refer to **Operating Modes and Memory Maps**.

EEON — EEPROM Enable

Refer to **Operating Modes and Memory Maps**.

Freescale Semiconductor, Inc. Electrically Erasable Programmable Read-Only Memory (EEPROM)

The 512 bytes of EEPROM in the MC68HC11A8 are located at \$B600 through \$B7FF. The EEON bit in CONFIG controls the presence or absence of the EEPROM in the memory map. When EEON = 1 (erased state), the EEPROM is enabled. When EEON = 0, the EEPROM is disabled and out of the memory map. EEON is reset to the value last programmed into CONFIG. An on-chip charge pump develops the high voltage required for programming and erasing. When the E clock is less than 1 MHz, select an internal clock. This drives the EEPROM charge pump by writing a one to the CSEL bit in the OPTION register.

The PPROG register controls the programming and erasing of the EEPROM. To erase the EEPROM, complete the following steps using the PPROG register:

1. Write to PPROG with the ERASE, EELAT, and appropriate BYTE and ROW bits set.
2. Write to the appropriate EEPROM address with any data. Row erase only requires a write to any location in the row. Bulk erase is accomplished by writing to any location in the array.
3. Write to PPROG with ERASE, EELAT, EEPGM, and the appropriate BYTE and ROW bits set.
4. Delay for 10 ms or more, as appropriate.
5. Clear the EEPGM bit in PPROG to turn off the high voltage.
6. Clear the PPROG register to reconfigure the EEPROM address and data buses for normal operation.

To program the EEPROM, complete the following steps using the PPROG register:

1. Write to PPROG with the EELAT bit set.
2. Write data to the desired address.
3. Write to PPROG with the EELAT and EEPGM bits set.
4. Delay for 10 ms or more, as appropriate.
5. Clear the EEPGM bit in PPROG to turn off the high voltage.
6. Clear the PPROG register to reconfigure the EEPROM address and data buses for normal operation.

ODD — Program Odd Rows in Half of EEPROM (TEST)

EVEN — Program Even Rows in Half of EEPROM (TEST)

BYTE — Byte/Other EEPROM Erase Mode

The BYTE bit overrides the ROW bit.

0 = Row or bulk erase mode is used

1 = Erase only one byte of EEPROM

ROW — Row/All EEPROM Erase Mode

The ROW bit is only valid when BYTE = 0.

0 = All 512 bytes of EEPROM are erased

1 = Erase only one 16-byte row of EEPROM

NOSEC — EEPROM Security Disable

NOSEC has no meaning unless the security mask option was specified before the MCU was manufactured.

- 0 = Security enabled (available as a mask option on MC68HC11A8 only)
- 1 = Security disabled

NOCOP — COP system disable

Refer to **Resets and Interrupts**.

ROMON — ROM Enable

Refer to **Operating Modes and Memory Maps**.

EEON — EEPROM Enable

Parallel Input/Output

The MC68HC11A8 has up to 38 input/output lines, depending on the operating mode. Port A has three input-only pins, four output-only pins, and one bidirectional I/O pin. Port A shares functions with the timer system.

Port B is an 8-bit output-only port in single-chip modes and is the high-order address in expanded modes.

Port C is an 8-bit bidirectional port in single-chip modes and the multiplexed address and data bus in expanded modes.

Port D is a 6-bit bidirectional port that shares functions with the serial systems.

Port E is an 8-bit input-only port that shares functions with the A/D system.

Simple and full handshake input and output functions are available on ports B and C lines in single-chip mode. A description of the handshake functions follows.

In port B simple strobed output mode, the STRB output is pulsed for two E-clock periods each time there is a write to the PORTB register. The INVB bit in the PIOC register controls the polarity of STRB pulses.

In port C simple strobed input mode, port C levels are latched into the alternate port C latch (PORTCL) register on each assertion of the STRA input. STRA edge select, flag and interrupt enable bits are located in the PIOC register. Any or all of the port C lines can still be used as general purpose I/O while in strobed input mode.

Port C full handshake mode involves port C pins and the STRA and STRB lines. Input and output handshake modes are supported, and output handshake mode has a three-stated variation. STRA is an edge detecting input, and STRB is a handshake output. Control and enable bits are located in the PIOC register.

In full input handshake mode, the MCU uses STRB as a "ready" line to an external system. Port C logic levels are latched into PORTCL when the STRA line is asserted by the external system. The MCU then deasserts STRB. The MCU reasserts STRB after the PORTCL register is read. A mix of latched inputs, static inputs, and static outputs is allowed on port C, differentiated by the data direction bits and use of the PORTC and PORTCL registers.

In full output handshake mode, the MCU writes data to PORTCL, which in turn asserts the STRB output to indicate that data is ready. The external system reads port C (the STRB output) and asserts the STRA input to acknowledge that data has been received.

In the three-state variation of output handshake mode, lines intended as three-state handshake outputs are configured as inputs by clearing the corresponding DDRC bits. The MCU writes data to PORTCL and asserts STRB. The external system responds by activating the STRA input, which forces the MCU to drive the data in PORTCL out on all of the port C lines. This mode variation does not allow part of port C to be used for static inputs while other port C pins are being used for handshake outputs. Refer to the PIOC register description.

Serial Communications Interface (SCI)

The SCI, a universal asynchronous receiver transmitter (UART) serial communications interface, is one of two independent serial I/O subsystems in the MC68HC11A8. It has a standard NRZ format (one start, eight or nine data, and one stop bit) and several baud rates available. The SCI transmitter and receiver are independent, but use the same data format and bit rate.

RESET: 1 1 0 0 0 0 0 0

TDRE — Transmit Data Register Empty Flag

Set if transmit data can be written to SCDR; if TDRE is zero, transmit data register is busy. Cleared by SCSR read with TDRE set followed by SCDR write.

TC — Transmit Complete Flag

Set if transmitter is idle (no data, preamble, or break transmission in progress). Cleared by SCSR read with TC set followed by SCDR write.

RDRF — Receive Data Register Full Flag

Set if a received character is ready to be read from SCDR. Cleared by SCSR read with RDRF set followed by SCDR read.

IDLE — Idle Line Detected Flag

Set if the RxD line is idle. IDLE flag is inhibited when RWU is set to one. Cleared by SCSR read with IDLE set followed by SCDR read. Once cleared, IDLE is not set again until the RxD line has been active and becomes idle again.

OR — Overrun Error Flag

Set if a new character is received before a previously received character is read from SCDR. Cleared by SCSR read with OR set followed by SCDR read.

NF — Noise Error Flag

Set if majority sample logic detects anything other than a unanimous decision. Cleared by SCSR read with NF set followed by SCDR read.

FE — Framing Error

Set if a 0 is detected where a stop bit was expected. Cleared by SCSR read with FE set followed by SCDR read.

Serial Peripheral Interface (SPI)

The SPI is one of two independent serial communications subsystems that allow the MCU to communicate synchronously with peripheral devices and other microprocessors. Data rates can be as high as one half of the E-clock rate when configured as master, and as fast as the E clock when configured as slave.

Main Timer

Freescale Semiconductor, Inc.

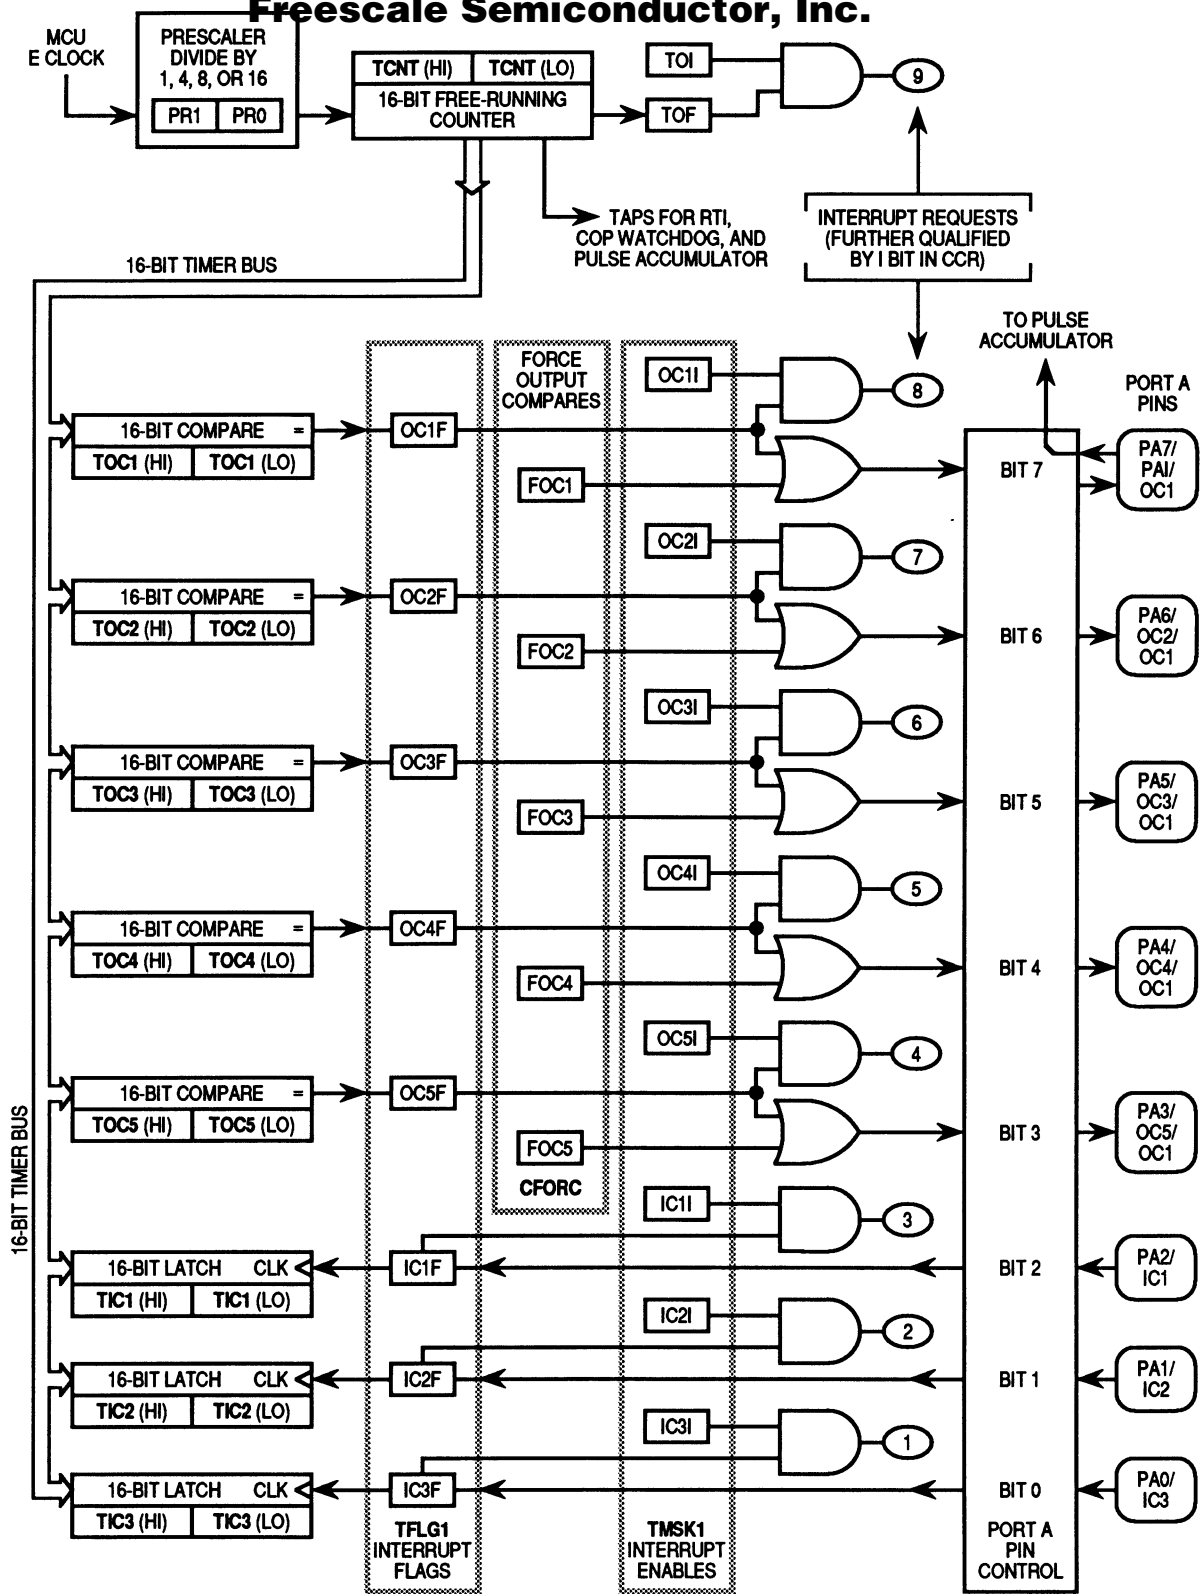

The main timer is based on a free-running 16-bit counter with a four-stage programmable prescaler. A timer overflow function allows software to extend the system's timing capability beyond the counter's 16-bit range.

The timer has three channels of input capture and five channels of output compare.

Refer to the following table for a summary of crystal-related frequencies and periods.

Pulse Accumulator

The MC68HC11A8 has an 8-bit counter that can be configured to operate as a simple event counter or for gated time accumulation, depending on the PAMOD bit in the PACTL register. The pulse accumulator counter can be read or written at any time.

The port A bit 7 I/O pin can be configured as a clock in event counting mode, or as a gate signal to enable a free-running clock (E divided by 64) in gated time accumulation mode.

Pulse Accumulator Timing

Analog-to-Digital Converter

The A/D converter system uses an all capacitive charge redistribution technique to convert analog signals to digital values. The MC68HC11A8 A/D system is an 8-channel, 8-bit, multiplexed-input, successive-approximation converter and is accurate to ± 1 least significant bit (LSB). It does not require external sample and hold circuits because of the type of charge redistribution technique used.

Dedicated lines V_{RH} and V_{RL} provide the reference supply voltage inputs. Refer to the A/D converter block diagram.

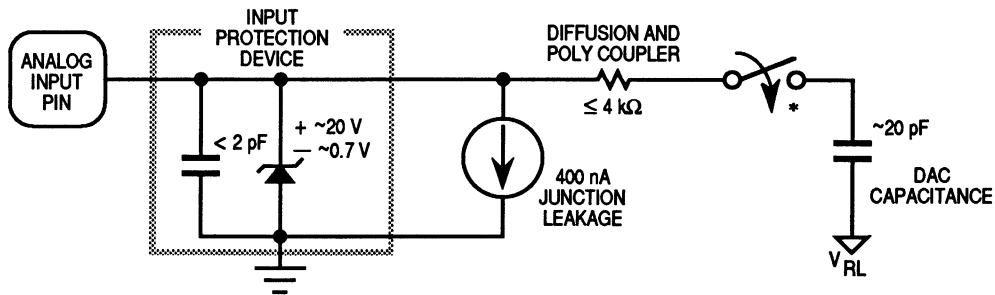

A multiplexer allows the single A/D converter to select one of 16 analog signals, as shown in the ADCTL register description.
