### 5.2 Hardware Monitor

For the 8-bit ADC has the 8mv LSB, the maximum input voltage of the analog pin is 2.048V. Therefore the voltage under 2.048V (ex: 1.5V) can be directly connected to these analog inputs. The voltage higher than 2.048V should be reduced by a factor with external resistors so as to obtain the input range. Only 3VCC/VSB/VBAT is an exception for it is main power of the F71869. Therefore 3VCC/VSB/VBAT can directly connect to this chip's power pin and need no external resistors. There are two functions in this pin with 3.3V. The first function is to supply internal analog power of the F71863 and the second function is that voltage with 3.3V is connected to internal serial resistors to monitor the +3.3V voltage. The internal serial resistors are two 150K ohm, so that the internal reduced voltage is half of +3.3V.

There are four voltage inputs in the F71869 and the voltage divided formula is shown as follows:

$$VIN = V_{+12V} \times \frac{R_2}{R_1 + R_2} \quad \text{where } V_{+12V} \text{ is the analog input voltage, for example.}$$

If we choose  $R_1=27K$ ,  $R_2=5.1K$ , the exact input voltage for  $V_{+12V}$  will be 1.907V, which is within the tolerance. As for application circuit, it can be refer to the figure shown as follows.

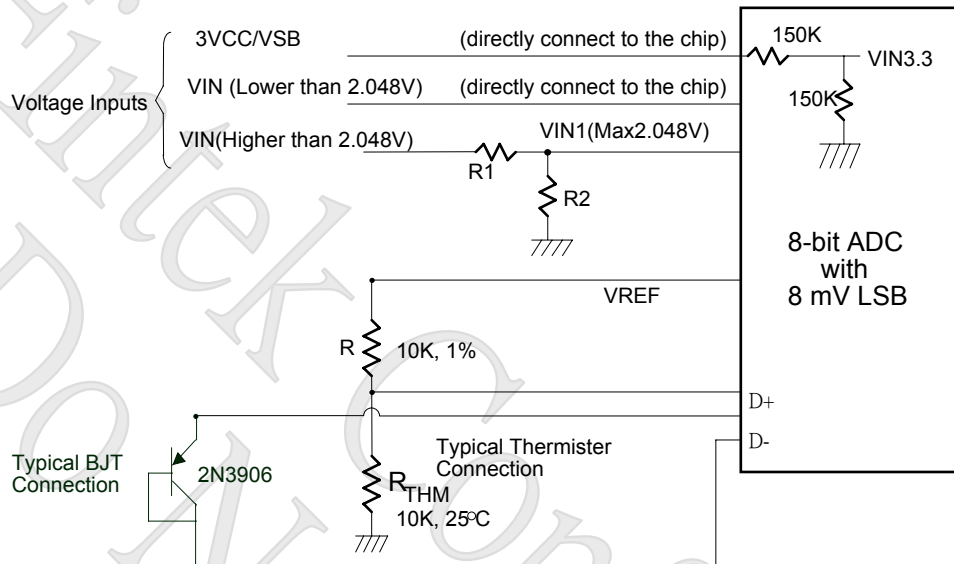

Figure 2. Hardware monitor configuration

The F71869 monitors three remote temperature sensors. These sensors can be measured from  $-40^{\circ}\text{C}$  to  $127^{\circ}\text{C}$ . More detail please refer register description.

### 5.2.2 Monitor Temperature from “Thermistor”

The F71869 can connect three thermistors to measure environment temperature or remote temperature. The specification of thermistor should be considered to (1)  $\beta$  value is 3435K (2) resistor value is 10K ohm at 25°C. In the Figure 2, the thermistor is connected by a serial resistor with 10K ohm, then being connected to VREF.

### 5.2.3 Monitor Temperature from “Thermal diode”

Also, if the CPU, GPU or external circuits provide thermal diode for temperature measurement, the F71869 is capable to these situations. The build-in reference table is for PNP 2N3906 transistor. In the Figure 2, the transistor is directly connected into temperature pins.

### 5.2.4 ADC Noise Filtering

The ADC is integrating type with inherently good noise rejection. Micro-power operation places constraints on high-frequency noise rejection; therefore, careful PCB board layout and suitable external filtering are required for high-accuracy remote measurement in electronically noisy environment. High frequency EMI is best filtered at D+ and D- with an external 2200pF capacitor. Too high capacitance may introduce errors due to the rise time of the switched current source. Nearly all noise sources tested cause the ADC measurement to be higher than the actual temperature, depending on the frequency and amplitude.

### 5.2.5 Monitor Temperature from “SMBus device”

F71869 provides SMBus block read/write compatible Platform Control Hub (PCH) EC SMBus protocol, and provides byte read/write protocol to read CPU and chipset thermal temperature information. For byte read /write protocol, F71869 supports 4-suit device address to read or write from device information. For block read/write, F71869 support 1 suits device address and maximum 17 byte count for read protocol to read from device information, and 4 byte count for write protocol to write information to device.

### 5.2.6 Monitor Temperature from “PECI”

F71869 support Intel PECI1.1/PECI\_Request/PECI\_Available interfaces to read temperature from PECI 1.1 device.

## F71869

### 5.2.7 Temperature HM\_IRQ Signal (HM\_IRQ# and PME#)

There are two mode of temperature (t1 to t4) HM\_IRQ function, and refer t1 to t4 temperature in the Figure 3 and 4.

#### 1. Hysteresis mode:

Over temperature event will trigger HM\_IRQ# that shown as figure. In hysteresis mode, when monitored temperature exceeds the high temperature threshold value, HM\_IRQ# will be asserted until the temperature goes below the hysteresis temperature.

Figure 3

#### 2. High low limit mode: (default):

When in high low limit mode HM\_IRQ# for temperature is shown as figure. When monitored temperature exceeds the over-temperature threshold value, HM\_IRQ# will be asserted until the temperature goes below the low limit temperature.

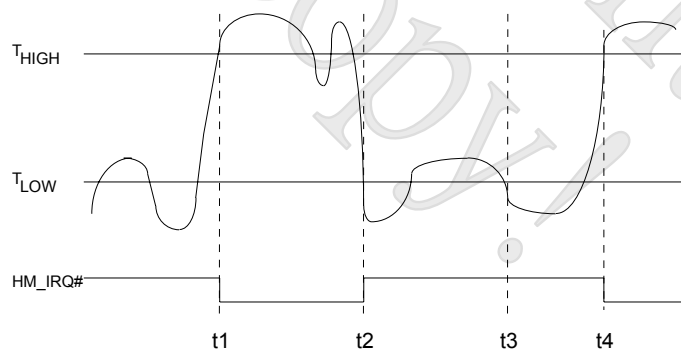

Figure 4

### 5.2.8 Temperature PME#

There are two mode of temperature PME# function:

#### 1. Hysteresis mode:

## F71869

PME# interrupt for temperature is shown as figure. Temperature exceeding high limit (low limit) or going below high hysteresis (low hysteresis) will cause an interrupt if the previous interrupt has been reset by writing "1" all the interrupt Status Register.

\*Interrupt Reset when Interrupt Status Registers are written 1

Figure 5 Hysteresis mode illustration

### 2. High low limit mode: (default):

PME# interrupt for temperature is shown as figure. Temperature exceeding high limit or going below low limit will cause an interrupt if the previous interrupt has been reset by writing "1" all the interrupt Status Register.

\*Interrupt Reset when Interrupt Status Registers are written 1

Figure 6 High low limit mode illustration

### 5.2.9 Fan Speed Count

Inputs are provided by the signals from fans equipped with tachometer outputs. The level of these signals should be set to TTL level, and maximum input voltage cannot be over 5V. If the input signals from the tachometer outputs are over the 5V, the external trimming circuit should be added to reduce the voltage to obtain the input specification.

Determine the fan counter according to:

$$Count = \frac{1.5 \times 10^6}{RPM}$$

In other words, the fan speed counter has been read from register, the fan speed can be evaluated by the following equation. As for fan, it would be best to use 2 pulses tachometer output per round.

$$RPM = \frac{1.5 \times 10^6}{Count}$$

### 5.2.10 Fan Speed Control

The F71869 provides 2 fan speed control methods: one is DAC FAN control and the other is PWM duty cycle.

#### 1. DAC Fan Control

The range of DC output is 0~3.3V, controlled by 8-bit register. 1 LSB is about 0.013V. The output DC voltage is amplified by external OP circuit, thus to reach maximum FAN OPERATION VOLTAGE, 12V. The output voltage will be given as followed:

$$Output\_voltage (V) = 3.3 \times \frac{\text{Programmed 8bit Register Value}}{255}$$

And the suggested application circuit for DAC fan control would be:

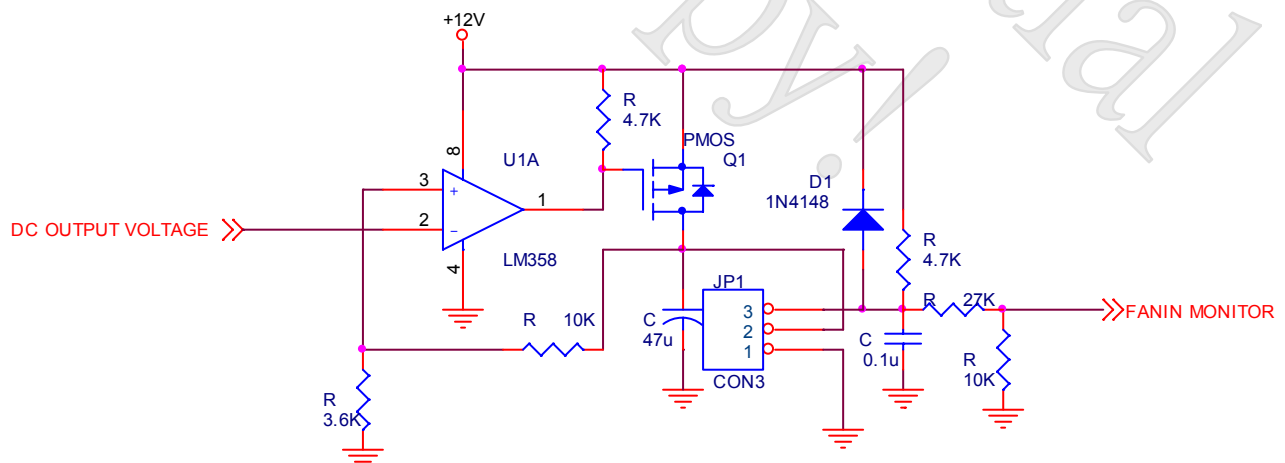

Figure 7 DAC fan control application circuit

## 2. PWM duty Fan Control

The duty cycle of PWM can be programmed by a 8-bit register. The default duty cycle is set to 100%, that is, the default 8-bit registers is set to FFh. The expression of duty can be represented as follows.

$$\text{Duty\_cycle(\%)} = \frac{\text{Programmed 8bit Register Value}}{255} \times 100\%$$

Figure 8 +12/5V PWM fan control application circuit

### 5.2.11 Fan Speed Control Mechanism

There are some modes to control fan speed and they are 1. Manual mode, 2. Stage auto mode 3. Linear auto mode. More detail, please refer the description of registers.

Each fan can be controlled by up to 8 kinds of temperature input. (1) D1+ temperature (2) D2+ temperature (3) D3+ temperature (4) PECl temperature (5) 4 suits SMBus master temperature. Please refer below structure diagram.

After the T0 ~ T7 setting ready, select S1 ~ S4 temperature machine from T0 ~ T7, these 4-set temperature data are for maximum temperature comparison.

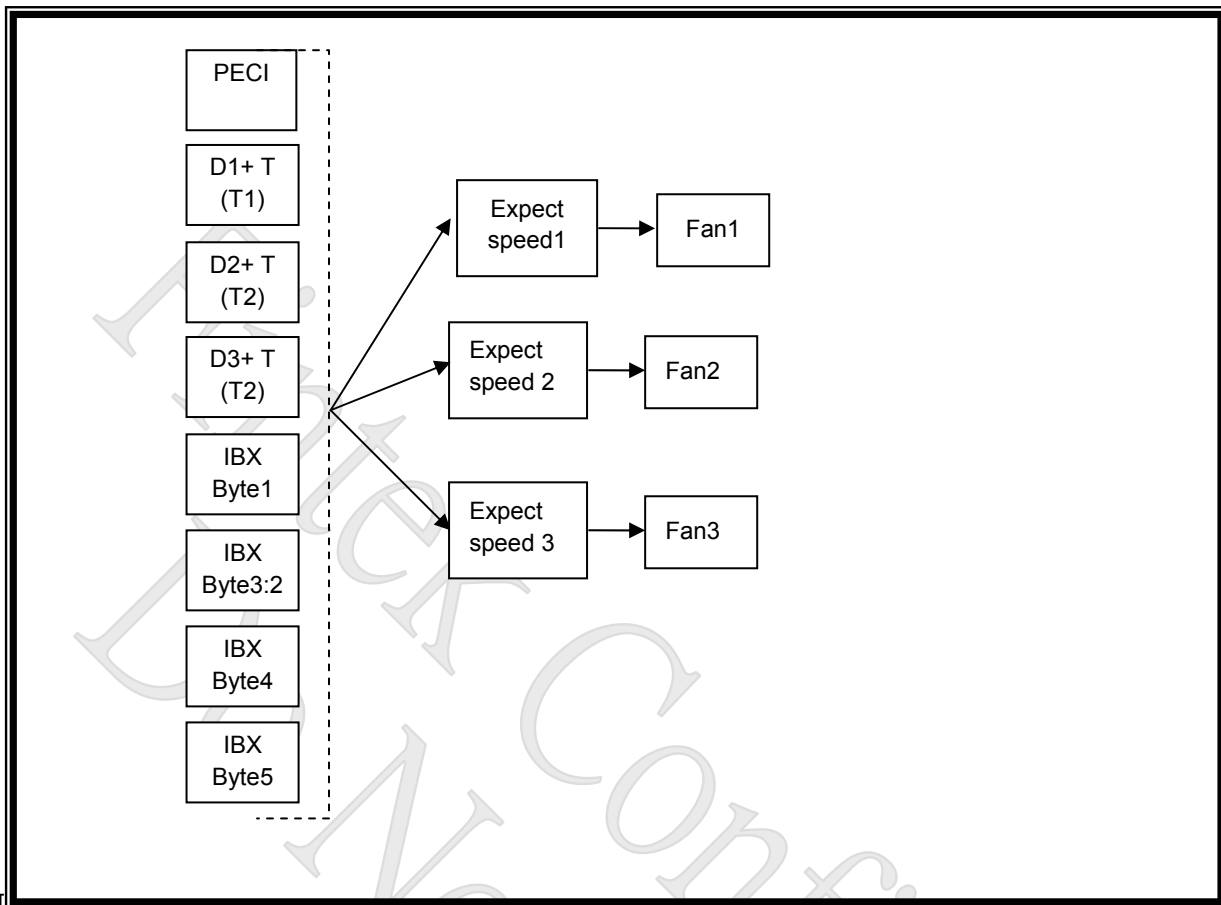

Figure 9 Relative temperature fan control

### 1. Manual mode

For manual mode, it generally acts as software fan speed control.

### 2. Stage auto mode

At this mode, the F71869 provides automatic fan speed control related to temperature variation of CPU/GPU or the system. The F71869 can provide two temperature boundaries and three intervals, and each interval has its related fan speed PWM duty. All these values should be set by BIOS first. Take figure 6-10 as example. When temperature boundaries are set as 45 and 75°C and there are three intervals. The related desired fan speed for every interval is 40%, 80% and 100% (fixed). When the temperature is within 45~75°C, the fan speed will follow 80% PWM duty and that define in registers. It can be said that the fan will be turned on with a specific speed set by BIOS and automatically controlled with the temperature variation. The F71869 will take charge of all the fan speed control without software support.

**F71869**

Figure 10 Stage mode fan control illustration-1

Below is a sample for Stage auto mode:

Set temperature as 60°C, 40°C and Duty as 100%, 70%, 50%

Figure 11 Stage mode fan control illustration-2

- Once temp. is under 40°C, the lowest fan speed keeps 50% PWM duty
- Once temp. is over 40°C, 60°C, the fan speed will vary from 70% to 100% PWM duty and increase with temperature
- Once temp. keeps in 55°C, fan speed keeps in 70% PWM duty
- If set the hysteresis as 3°C (default 4°C), once temp reduces under 57°C, fan speed reduces to 70% PWM duty and stays there.

### 3. Linear auto mode

Otherwise, F71869 supports linear auto mode. Below has an example to describe this mode. More detail, please refer the register description.

Set temperature as 70°C, 40°C and Duty as 100%, 70%, 40%

Figure 12 Linear mode fan control illustration

- Once temp. is under 40°C, the lowest fan speed keeps 40% PWM duty
- Once temp. is over 40°C and under 70°C, the fan speed will vary from 40% to 70% PWM duty and linearly increase with temp. variation. The temp.-fan speed monitoring and flash interval is 1sec.
- Once temp. goes over 70°C, fan speed will directly increase to 100% PWM duty (full speed)
- If set the hysteresis as 5°C (default is 4°C), once temp reduces under 65°C (not 70°C), fan speed reduces from 100% PWM duty and decrease linearly with temp..

### 5.2.12 FAN\_FAULT#

Fan\_Fault# will be asserted when the fan speed doesn't meet the expected fan speed within a programmable period (default is 11 seconds) or when fan stops with respect to PWM duty-cycle which should be able to turn on the fan. There are two conditions may cause the FAN\_FAULT# event.

- When PWM\_Duty reaches 0xFF, the fan speed count can't reach the fan expected count in time.

Figure 13 FAN\_FAULT# event

- After the period of detecting fan full speed, PWM\_Duty > Min. Duty, fan count is still in 0xFFFF.

### 5.3 ACPI Function

The Advanced Configuration and Power Interface (ACPI) is a system for controlling the use of power in a computer. It lets computer manufacturer and user to determine the computer's power usage dynamically.

There are three ACPI states that are of primary concern to the system designer and they are designated S0, S3 and S5. S0 is a full-power state; the computer is being actively used in this state. The other two are called sleep states and reflect different power consumption when power-down. S3 is a state that the processor is powered down but the last procedural state is being stored in memory which is still active. S5 is a state that memory is off and the last procedural state of the processor has been stored to the hard disk. Take S3 and S5 as comparison, since memory is fast, the computer can quickly come back to full-power state, the disk is slower than the memory and the computer takes longer time to come back to full-power state. However, since the memory is off, S5 draws the minimal power comparing to S0 and S3.

It is anticipated that only the following state transitions may happen:

$S0 \rightarrow S3$ ,  $S0 \rightarrow S5$ ,  $S5 \rightarrow S0$ ,  $S3 \rightarrow S0$  and  $S3 \rightarrow S5$ .

Among them,  $S3 \rightarrow S5$  is illegal transition and won't be allowed by state machine. It is necessary to enter S0 first in order to get to S5 from S3. As for transition  $S5 \rightarrow S3$  will occur only as an immediate state during state transition from  $S5 \rightarrow S0$ . It isn't allowed in the normal state transition.

The below diagram described the timing, the always on and always off, keep last state could be set in control register. In keep last state mode, one register will keep the status of before power loss. If it is power on before power loss, it will remain power on when power is resumed, otherwise, if it is power off before power loss, it will remain power off when power is resumed.

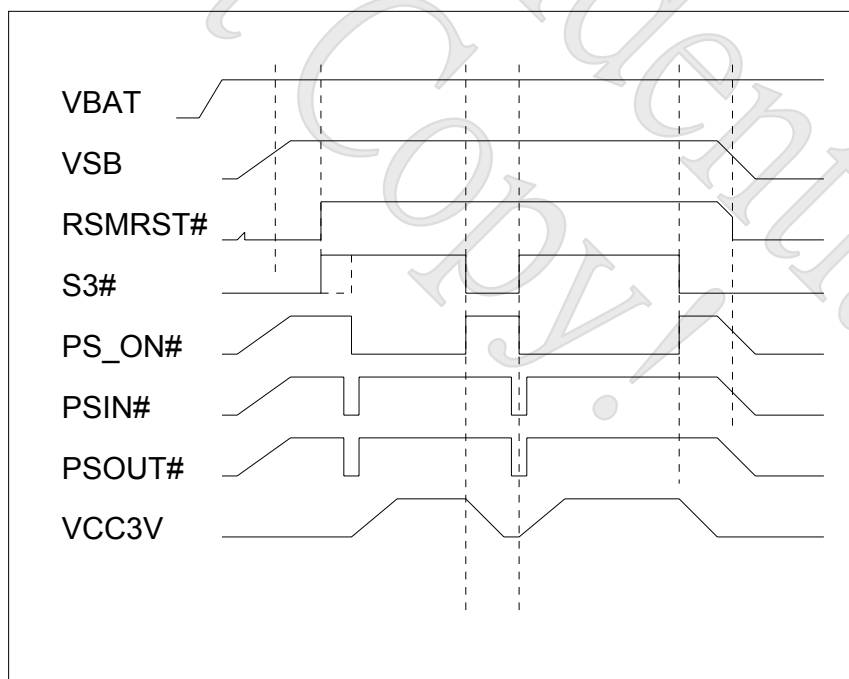

Figure 14 Default timing: Always off

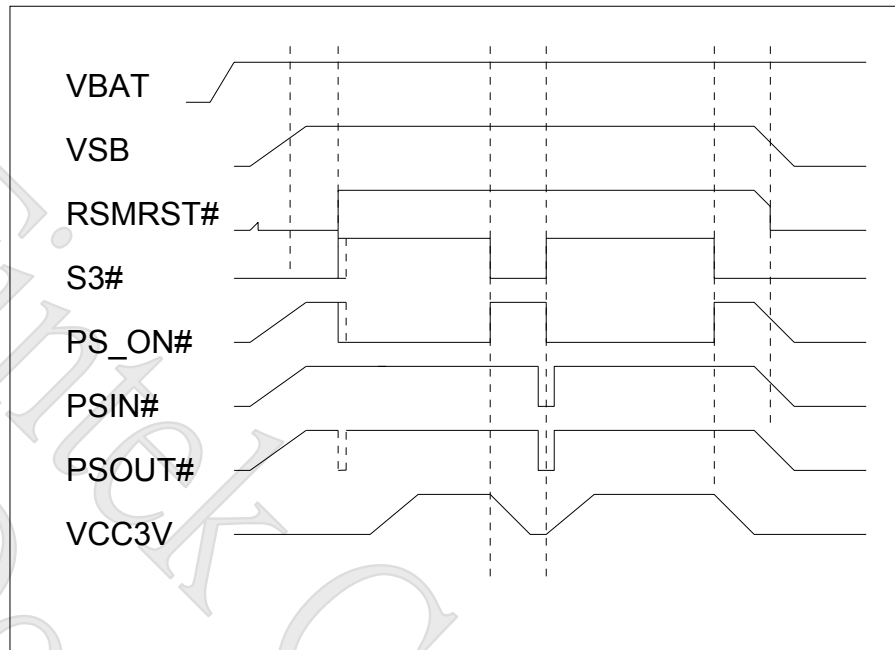

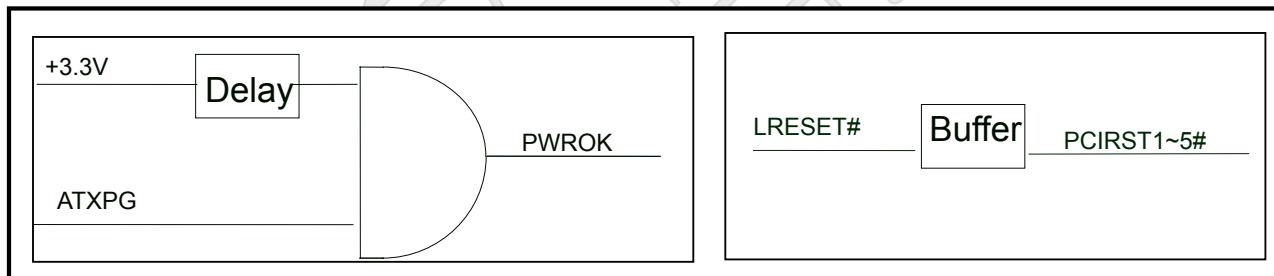

Figure 15 Optional timing: Always on

### PCI Reset and PWROK Signals

The F71869 supports 5 output buffers for 5 reset signals.

So far as the PWROK issue is as the figure above. PWROK is delayed 400ms (default) as VCC arrives 2.8V, and the delay timing can be programmed by register (100ms ~ 400ms). An additional delay could be added to PWROK (0ms, 100ms, 200ms and 400ms). Default is 0ms. If RSTCION# and PCIRST4#/PCIRST5# are enabled, RSTCON# could be programmed to be asserted via PWROK or PCIRST4#/PCIRST5#.

## 5.4 Timing Control Sequence

The F71869 offers 4 timing pins which are designed for AMD platform power sequence control including VDIMM, VDDA, Vcore, and VLDT (default) or other timing application purposes. All the timings on/off are relative to S3#/S5# and can be programmed by the register 0x0AF7. As shown in the Figure 20, the default timings of TIMING\_1~4 are displayed in blue lines, and all the timings are enabled in the

## F71869

S0 state except TIMING\_1. However, TIMING\_2~4 can be programmed to enable in the S3 state, and TIMING\_1 can also be programmed to disable in the S3 state, like the dotted blue line shown in the Figure 20.

VDDOK\_D400 is the PWROK delay timing from VDD3VOK. The default setting is that delay 400ms, there are 100ms, 200ms, and 300ms for option. It can be set in the register 0x0AF5.

Figure 16 Timing on/off sequence

### 5.5 ST1, ST2 and ATX\_PWRGDSW Timing

The F71869 provides three additional timing switching pins which are named as ST1, ST2 and ATXPWRGDSW. They can be applied in the certain applications about power switch which depends on the ACPI states. The detail timing can be referred in the following diagrams. The default timing of ATX\_PWRGDSW in the S5 state is low, but it can be programmed high by the register 0x0AF6.

## 5.6 AMD TSI and Intel PECI Function

The F71869 provides Intel PECI/AMD TSI interfaces for new generational CPU temperature sensing. In AMDSI interface, there are SIC and SID signals for temperature information reading from AMD CPU. The SIC signal is for clocking use, the other is for data transferring. More details, please refer register description.

## F71869

In Intel PECI interface, the F71869 can connect to CPU directly. The F71869 can read the temperature data from CPU, then the fan control machine of F71869 can implement the Fan to cool down CPU temperature. The application circuit is as below. More details, please refer the register description.

## 5. Register Description

The configuration register is used to control the behavior of the corresponding devices. To configure the register, using the index port to select the index and then writing data port to alter the parameters. The default index port and data port are 0x4E and 0x4F respectively. Pull down the SOUT1 pin to change the default value to 0x2E/0x2F. To enable configuration, the entry key 0x87 must be written to the index port. To disable configuration, write exit key 0xAA to the index port. Following is a example to enable configuration and disable configuration by using debug.

```
-o 4e 87
-o 4e 87      (enable configuration)
-o 4e aa      (disable configuration)
```

The Following is a register map (total devices) grouped in hexadecimal address order, which shows a summary of all registers and their default value. Please refer each device chapter if you want more detail information.
