

# 12V/5V Low Dropout Dual Regulator with ENABLE

## Description

The CS-8155 is a low dropout, 12V high current regulator. Also included is a standby 5V/10mA output for powering systems with standby memory. Quiescent current drain is less than 2mA when supplying 10mA loads from the standby regulator.

In automotive applications, the CS-8155 and all regulated circuits are protected from reverse battery installations, as well as two-battery jumps. During

line transients, such as a 60V load dump, the 0.75A regulator will automatically shut down to protect both internal circuits and the load, while the standby regulator will continue to power any standby load.

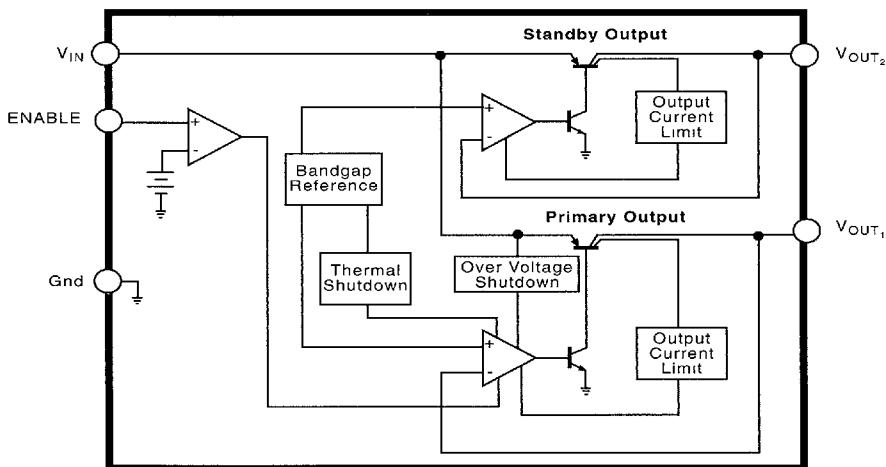

The CS-8155 is packaged in a 5-lead TO-220, with copper tab for connection to a heat sink, if necessary.

## Absolute Maximum Ratings

### Input Voltage

Operating Range.....	-0.5V to 26V
Overvoltage Protection.....	60V
Internal Power Dissipation .....	Internally Limited
Operating Temperature Range.....	-40°C to +125°C
Junction Temperature Range.....	-40°C +150°C
Storage Temperature Range.....	-65°C to +150°C
Soldering Lead Temperature: TO-220 (10sec).....	260°C

**Definition of Terms**

**Dropout Voltage:** The input-output voltage differential at which the circuit ceases to regulate against further reduction in input voltage. Measured when the output voltage has dropped 100mV from the nominal value obtained at 14V input, dropout voltage is dependent upon load current and junction temperature.

**Input Voltage:** The DC voltage applied to the input terminals with respect to ground.

**Input Output Differential:** The voltage difference between the unregulated input voltage and the regulated output voltage for which the regulator will operate.

**Line Regulation:** The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

**Load Regulation:** The change in output voltage for a change in load current at constant chip temperature.

**Long Term Stability:** Output voltage stability under accelerated life-test conditions after 1000 hours with maximum rated voltage and junction temperature.

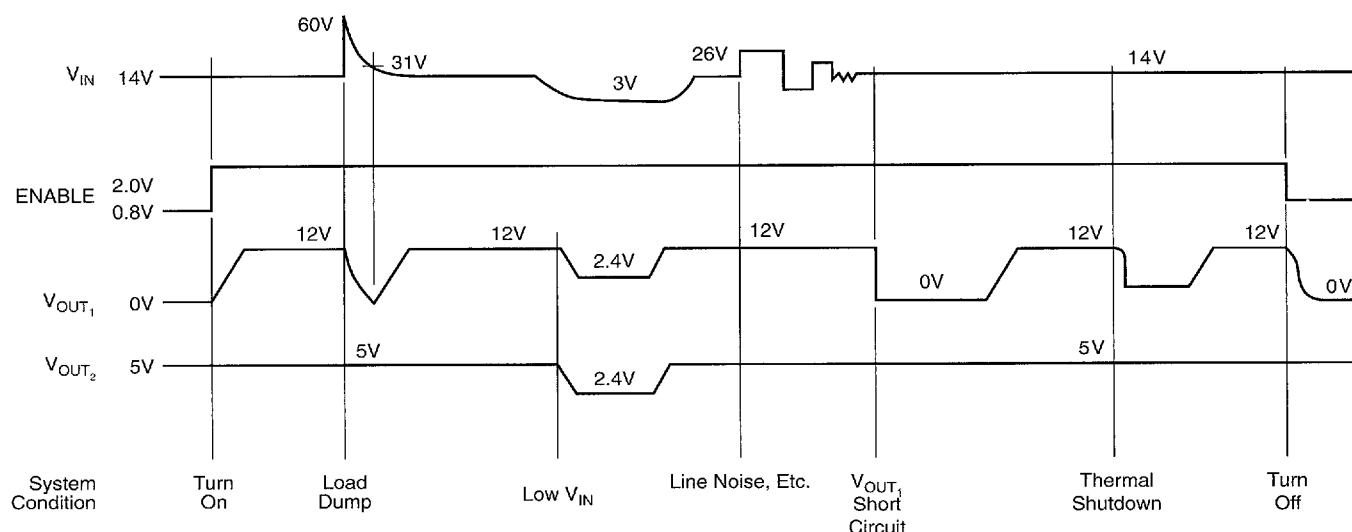

**Output Noise Voltage:** The rms AC voltage at the output, with constant load and no input ripple, measured over a specified frequency range.

**Quiescent Current:** The part of the positive input current that does not contribute to the positive load current, i.e., the regulator ground lead current.

**Ripple Rejection:** The ratio of the peak-to-peak input ripple voltage to the peak-to-peak output ripple voltage.

**Temperature Stability of V<sub>OUT</sub>:** The percentage change in output voltage for a thermal variation from room temperature to either temperature extreme.

**Current Limit:** Peak current that can be delivered to the output.

**Typical Circuit Waveform****Application Notes****External Capacitors**

The CS-8155 output capacitors are required for stability. Without them, the regulator outputs will oscillate. The 10µF shown are the minimum recommended values. Actual size and type may vary depending upon the application load and temperature range. Capacitor effective series resistance (ESR) is also a factor in the IC stability. Worst-case is determined at the minimum ambient temperature and maximum load expected.

Output capacitors can be increased in size to any desired value above the minimum. One possible purpose of this would be to maintain the output voltages during brief conditions of negative input transients that might be char-

acteristic of a particular system.

Capacitors must also be rated at all ambient temperatures expected in the system. To maintain regulator stability down to -40°C, capacitors rated at that temperature must be used.

**Standby Output**

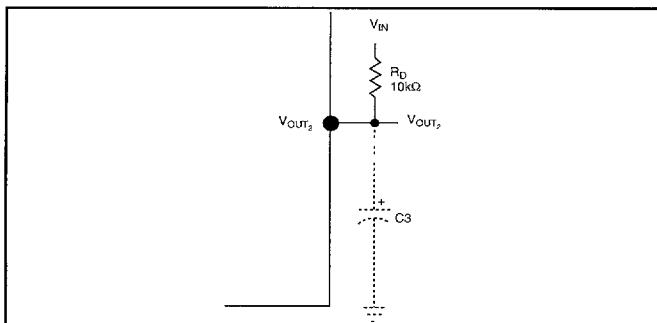

The CS-8155 differs from most fixed voltage-regulators in that it is equipped with two regulator outputs instead of one. The additional output is intended for use in systems requiring standby memory circuits. While the high current regulator output can be controlled with the ENABLE pin described below, the standby output remains on

## Application Notes: continued

under all conditions as long as sufficient input voltage is applied to the IC. Thus, memory and other circuits powered by this output remain unaffected by positive line transients, thermal shutdown, etc.

The standby regulator circuit is designed so that the quiescent current to the IC is very low (<2mA) when the other regulator output is off.

In applications where the standby output is not needed, it may be disabled by connecting a resistor from the standby output to the supply voltage. This eliminates the need for a capacitor on the output to prevent unwanted oscillations. The value of the resistor depends upon the minimum input voltage expected for a given system. Since the standby output is shunted with an internal 6.0V Zener, the current through the external resistor should be sufficient to bias  $V_{OUT_2}$  up to this point. Approximately 60 $\mu$ A will suffice, resulting in a 10k $\Omega$  external resistor for most applications.

Disabling  $V_{OUT_2}$ , when it is not needed; C3 is no longer needed.

Unlike the standby regulated output, which must remain on whenever possible, the high current regulated output is fault protected against overvoltage and also incorporates thermal shutdown. If the input voltage rises above approximately 30V (e.g., load dump), this output will automatically shutdown. This protects the internal circuit-

ry and enables the IC to survive higher voltage transients than would otherwise be expected. Thermal shutdown is effective against die overheating since the high current output is the dominant source of power dissipation in the IC.

### ENABLE

The enable function controls  $V_{OUT_1}$ . When ENABLE is high (5V),  $V_{OUT_1}$  is on. When ENABLE is low,  $V_{OUT_1}$  is off.

### Thermal Management

The CS-8155 operates up to a junction temperature ( $T_J$ ) of 150°C. However, the IC's worst-case operating conditions determine the maximum ambient temperature for a given application. The maximum ambient temperature may be calculated by the following equation:

$$T_A = T_J - [(V_{IN} - V_{O1})I_{O1} + (V_{IN} - V_{O2})I_{O2} + V_{IN}I_Q] R_{JA}$$

where  $T_J$  = 150°C

$V_{IN}$  = Maximum Input Voltage

$V_{O1}$  = 12V

$I_{O1}$  = 12V Maximum Output Current

$V_{O2}$  = 5V

$I_{O2}$  = 5V Maximum Output Current

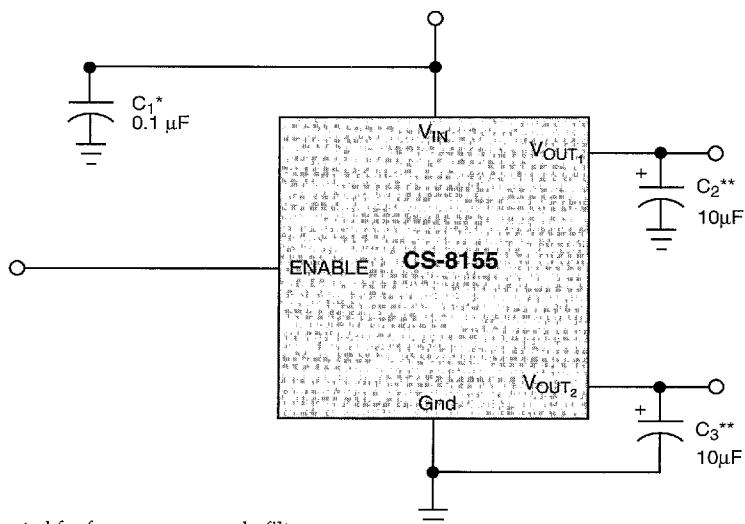

$I_Q$  = IC's Quiescent current at Maximum Output Currents

The TO-220 thermal resistances are listed under the package thermal data heading. When using a heat sink:

$$R_{JA} = R_{JC} + R_{CA} = 3.5^{\circ}\text{C}/\text{W} + R_{CA}$$

where  $R_{CA}$  = Heat Sink Thermal Resistance

## Test & Application Circuit

### NOTES:

\* C1 required if regulator is located far from power supply filter.

\*\* C2 required for stability value may be increased. Capacitor must operate at minimum temperature expected.
