**Stacked Multi-Chip Product (MCP)
128/64 Megabit (8M/4M x 16-bit) CMOS 1.8 Volt-only,
Simultaneous Read/Write, Burst Mode Flash Memory
with CosmoRAM**

Data Sheet

PRELIMINARY

Notice to Readers: This document indicates states the current technical specifications regarding the Spansion product(s) described herein. The Preliminary status of this document indicates that a product qualification has been completed, and that initial production has begun. Due to the phases of the manufacturing process that require maintaining efficiency and quality, this document may be revised by subsequent versions or modifications due to changes in technical specifications.

Notice On Data Sheet Designations

Spansion LLC issues data sheets with Advance Information or Preliminary designations to advise readers of product information or intended specifications throughout the product life cycle, including development, qualification, initial production, and full production. In all cases, however, readers are encouraged to verify that they have the latest information before finalizing their design. The following descriptions of Spansion data sheet designations are presented here to highlight their presence and definitions.

Advance Information

The Advance Information designation indicates that Spansion LLC is developing one or more specific products, but has not committed any design to production. Information presented in a document with this designation is likely to change, and in some cases, development on the product may discontinue. Spansion LLC therefore places the following conditions upon Advance Information content:

"This document contains information on one or more products under development at Spansion LLC. The information is intended to help you evaluate this product. Do not design in this product without contacting the factory. Spansion LLC reserves the right to change or discontinue work on this proposed product without notice."

Preliminary

The Preliminary designation indicates that the product development has progressed such that a commitment to production has taken place. This designation covers several aspects of the product life cycle, including product qualification, initial production, and the subsequent phases in the manufacturing process that occur before full production is achieved. Changes to the technical specifications presented in a Preliminary document should be expected while keeping these aspects of production under consideration. Spansion places the following conditions upon Preliminary content:

"This document states the current technical specifications regarding the Spansion product(s) described herein. The Preliminary status of this document indicates that product qualification has been completed, and that initial production has begun. Due to the phases of the manufacturing process that require maintaining efficiency and quality, this document may be revised by subsequent versions or modifications due to changes in technical specifications."

Combination

Some data sheets will contain a combination of products with different designations (Advance Information, Preliminary, or Full Production). This type of document will distinguish these products and their designations wherever necessary, typically on the first page, the ordering information page, and pages with DC Characteristics table and AC Erase and Program table (in the table notes). The disclaimer on the first page refers the reader to the notice on this page.

Full Production (No Designation on Document)

When a product has been in production for a period of time such that no changes or only nominal changes are expected, the Preliminary designation is removed from the data sheet. Nominal changes may include those affecting the number of ordering part numbers available, such as the addition or deletion of a speed option, temperature range, package type, or V_{IO} range. Changes may also include those needed to clarify a description or to correct a typographical error or incorrect specification. Spansion LLC applies the following conditions to documents in this category:

"This document states the current technical specifications regarding the Spansion product(s) described herein. Spansion LLC deems the products to have been in sufficient production volume such that subsequent versions of this document are not expected to change. However, typographical or specification corrections, or modifications to the valid combinations offered may occur."

Questions regarding these document designations may be directed to your local AMD or Fujitsu sales office.

S71WS-J Based MCPs

Stacked Multi-Chip Product (MCP)
128/64 Megabit (8M/4M x 16-bit) CMOS 1.8 Volt-only,
Simultaneous Read/Write, Burst Mode Flash Memory
with CosmoRAM

Data Sheet

PRELIMINARY

Distinctive Characteristics

MCP Features

- Power supply voltage of 1.7 to 1.95V
- Speed: 66MHz
- Packages:

- 8 x 11.6mm, 84 ball FBGA
- 7 x 9mm, 80-ball FBGA
- Operating Temperature
 - -25°C to +85°C

General Description

The S71WS series is a product line of stacked Multi-Chip Product (MCP) packages and consists of:

- One or more flash memory die
- pSRAM

The products covered by this document are listed in the table below. For details about their specifications, please refer to the individual constituent datasheets for further details:

| | | Flash Memory Density | | |
|------------------|------|----------------------|-------------|-------------|
| | | 256Mb | 128Mb | 64Mb |
| pSRAM Density | 64Mb | S71WS256JC0 | S71WS128JC0 | |
| | 32Mb | | S71WS128JB0 | S71WS064JB0 |
| | 16Mb | | S71WS128JA0 | S71WS064JA0 |

Product Selector Guide

| Device-Model# | Flash Density | pSRAM Density | Flash Speed (MHz) | pSRAM Speed (MHz/ns) | Supplier | Package | Availability Status |
|----------------|---------------|---------------|-------------------|----------------------|-----------|--------------------------|---------------------|
| S71WS064JA0-2Y | 64Mb | 16Mb | 66 | 66/70 | Cosmo RAM | 7x9x1.2mm 80-ball | Preliminary |
| S71WS064JB0-2Y | | | | | Cosmo RAM | | Preliminary |
| S71WS128JA0-AY | 128Mb | 32Mb | | | Cosmo RAM | 8x11.6x1.2 mm 84-ball | Preliminary |
| S71WS128JB0-AY | | | | | Cosmo RAM | | Preliminary |
| S71WS128JC0-AY | | | | | Cosmo RAM | | Preliminary |
| S71WS256JC0-TY | 256Mb | 64Mb | | | Cosmo RAM | 8x11.6x1.4 mm 84-ball | Preliminary |

Revision Summary I83

Revision Summary

MCP Block Diagram

Notes:

1. R-CRE is only present in CellularRAM-compatible pSRAM.
2. R-CE2 is only present in CosmoRAM-compatible pSRAM.
3. For 1 Flash = pSRAM, F1-CE# = CE#. For 2 Flash + pSRAM, CE# = F1-CE# and F2-CE# is the chip-enable pin for the second Flash.
4. Only needed for S71WS256JC0, and S70WS256J00.
5. CLK and AVD# not applicable for 16Mb pSRAM.

Connection Diagrams

(CosmoRAM Type-based)

84-ball Fine-Pitch Ball Grid Array
CosmoRAM-based Pinout (Top View, Balls Facing Down)

Notes:

- In MCP's based on a single S29WSxxxJ (S71WSxxxJ), ball B5 is RFU. In MCP's based on two S29WSxxxJ (S71WS256J), ball B5 is CE#f2 or F2-CE#.
- Addresses are shared between Flash and RAM depending on the density of the pSRAM.

| MCP | Flash-only Addresses | Shared Addresses |
|-------------|----------------------|------------------|
| S71WS064JA0 | A21-A20 | A19-A0 |
| S71WS064JB0 | A21 | A20-A0 |
| S71WS128JA0 | A22-A20 | A19-A0 |
| S71WS128JB0 | A22-A21 | A19-A0 |
| S71WS128JC0 | A22 | A21-A0 |

| MCP | Flash-only Addresses | Shared Addresses |
|-------------|----------------------|------------------|
| S71WS256JC0 | A22 | A21-A0 |

Special Handling Instructions For FBGA Package

Special handling is required for Flash Memory products in FBGA packages.

Flash memory devices in FBGA packages may be damaged if exposed to ultrasonic cleaning methods. The package and/or data integrity may be compromised if the package body is exposed to temperatures above 150°C for prolonged periods of time.

(CosmoRAM Type-based)

80-ball Fine-Pitch Ball Grid Array CosmoRAM-based Pinout (Top View, Balls)

Notes:

- In MCP's based on a single S29WSxxxJ (S71WSxxxJ), ball B5 is RFU. In MCP's based on two S29WSxxxJ (S71WS256J), ball B5 is CE#f2 or F2-CE#.
- Addresses are shared between Flash and RAM depending on the density of the pSRAM.
- The 80-ball pinout is applicable only to those MCPs with Flash density of 64Mb or 32Mb. For all the other MCPs included in this datasheet, please use the 84-ball pinout for design.

| MCP | Flash-only Addresses | Shared Addresses |
|-------------|----------------------|------------------|
| S71WS064JA0 | A21-A20 | A19-A0 |
| S71WS064JB0 | A21 | A20-A0 |

| MCP | Flash-only Addresses | Shared Addresses |
|-------------|----------------------|------------------|
| S71WS128JA0 | A22-A20 | A19-A0 |
| S71WS128JB0 | A22-A21 | A19-A0 |
| S71WS128JC0 | A22 | A21-A0 |
| S71WS256JC0 | A22 | A21-A0 |

Special Handling Instructions For FBGA Package

Special handling is required for Flash Memory products in FBGA packages.

Flash memory devices in FBGA packages may be damaged if exposed to ultrasonic cleaning methods. The package and/or data integrity may be compromised if the package body is exposed to temperatures above 150°C for prolonged periods of time.

Lookahead Connection Diagram

Notes:

1. F1 and F2 denote XIP/Code Flash, while F3 and F4 denote Data/Companion Flash.
2. In addition to being defined as F2-CE#, Ball C5 can also be assigned as F1-CE2# for code flash that has two chip enable signals.
3. For MCPs requiring 3.0V Vcc and 1.8V Vio, use the 1.8V Look-ahead Pinout in order to accommodate extra AVD, MRS and CLK pins for the pSRAM (if needed).
4. Refer to Application Note on pinout subsets to match the package size offerings.
5. Ball B5 is shared between Flash RDY and RAM WAIT# signals.

Input/Output Descriptions

| | | |
|-------------------|---|---|
| A22-A0 | = | Address inputs |
| DQ15-DQ0 | = | Data input/output |
| OE# | = | Output Enable input. Asynchronous relative to CLK for the Burst mode. |
| WE# | = | Write Enable input. |
| V _{SS} | = | Ground |
| NC | = | No Connect; not connected internally |
| RDY | = | Ready output. Indicates the status of the Burst read (shared with WAIT# pin of RAM). |
| CLK | = | Clock input. In burst mode, after the initial word is output, subsequent active edges of CLK increment the internal address counter. Should be at V _{IL} or V _{IH} while in asynchronous mode |
| AVD# | = | Address Valid input. Indicates to device that the valid address is present on the address inputs. Low = for asynchronous mode, indicates valid address; for burst mode, causes starting address to be latched. High = device ignores address inputs |
| F-RST# | = | Hardware reset input. Low = device resets and returns to reading array data |
| F-WP# | = | Hardware write protect input. At V _{IL} , disables program and erase functions in the four outermost sectors. Should be at V _{IH} for all other conditions. |
| F-ACC | = | Accelerated input. At V _{HH} , accelerates programming; automatically places device in unlock bypass mode. At V _{IL} , disables all program and erase functions. Should be at V _{IH} for all other conditions. |
| R-CE1# | = | Chip-enable input for pSRAM. |
| F1-CE# | = | Chip-enable input for Flash 1. Asynchronous relative to CLK for Burst Mode. |
| R-CRE | = | Control Register Enable (Only for MCPs with CellularRAM pSRAM). |
| F-V _{CC} | = | Flash 1.8 Volt-only single power supply. |
| R-V _{CC} | = | pSRAM Power Supply. |
| R-UB# | = | Upper Byte Control (pSRAM). |
| R-LB# | = | Lower Byte Control (pSRAM). |
| F2-CE# | = | Chip-enable input for Flash 2. Asynchronous relative to CLK for burst mode (needed only for S71WS256J). |
| DNU | = | Do not use. Reserved for future Spansion products. |
| R-CE2 | = | Chip-enable input for pSRAM |

Ordering Information

The order number is formed by a valid combinations of the following:

| S71WS064JA0 Valid Combinations (WS064J Flash + I6Mb pSRAM) | | | | Material Set | Supplier |
|--|-----------------|-------------------|-------------|-------------------|----------|
| Base Ordering Part Number | Package Marking | Temperature Range | Burst Speed | | |
| S71WS064JA0BAW2Y | 71WS064JA0BAW2Y | -25°C to +85°C | 66 MHz | Pb-free compliant | CosmoRAM |
| S71WS064JA0BFW2Y | 71WS064JA0BFW2Y | -25°C to +85°C | | Pb-free | |

Notes:

- Type 0 is standard. Specify other options as required.
- BGA package marking omits leading "S" and packing type designator from ordering part number.

Valid Combinations

Valid Combinations list configurations planned to be supported in volume for this device. Consult your local sales office to confirm availability of specific valid combinations and to check on newly released combinations.

| S71WS064JB0 Valid Combinations (WS064J Flash + 32Mb pSRAM) | | | | Material Set | Supplier |
|--|-----------------|-------------------|-------------|-------------------|----------|
| Base Ordering Part Number | Package Marking | Temperature Range | Burst Speed | | |
| S71WS064JB0BAW2Y | 71WS064JB0BAW2Y | -25°C to +85°C | 66 MHz | Pb-free compliant | CosmoRAM |
| S71WS064JB0BFW2Y | 71WS064JB0BFW2Y | -25°C to +85°C | | Pb-free | |

Notes:

1. Type 0 is standard. Specify other options as required.
2. BGA package marking omits leading "S" and packing type designator from ordering part number.

Valid Combinations

Valid Combinations list configurations planned to be supported in volume for this device. Consult your local sales office to confirm availability of specific valid combinations and to check on newly released combinations.

| S71WS128JA0 Valid Combinations (WS128J Flash + 16Mb pSRAM) | | | | Material Set | Supplier |

S29WSI28/064J

Flash Family for Multi-Chip Products (MCP)
I28/64 Megabit (8/4 M x 16-Bit) CMOS 1.8 Volt-only
Simultaneous Read/Write, Burst Mode Flash Memory

PRELIMINARY

Distinctive Characteristics

Architectural Advantages

- **Single 1.8 volt read, program and erase (1.65 to 1.95 volt)**
- **Manufactured on 0.11 μm process technology**
- **VersatileIO™ (V_{IO}) Feature**
 - Device generates data output voltages and tolerates data input voltages as determined by the voltage on the V_{IO} pin
 - 1.8V compatible I/O signals (1.65-1.95 V)
- **Simultaneous Read/Write operation**
 - Data can be continuously read from one bank while executing erase/program functions in other bank
 - Zero latency between read and write operations
 - Four bank architecture: WS128J: 16Mb/48Mb/48Mb/16Mb, WS064J: 8Mb/24Mb/24Mb/8Mb
- **Programmable Burst Interface**
 - 2 Modes of Burst Read Operation
 - Linear Burst: 8, 16, and 32 words with wrap-around
 - Continuous Sequential Burst
- **Secured Silicon Sector region**
 - 128 words accessible through a command sequence, 64words for the Factory Secured Silicon Sector and 64words for the Customer Secured Silicon Sector.
- **Sector Architecture**

4 Kword x 16 boot sectors, eight at the top of the address range, and eight at the bottom of the address range

 - **WS128J:** 4 Kword X 16, 32 Kword x 254 sectors
Bank A: 4 Kword x 8, 32 Kword x 31 sectors
Bank B: 32 Kword x 96 sectors
Bank C: 32 Kword x 96 sectors
Bank D: 4 Kword x 8, 32 Kword x 31 sectors
 - **WS064J:** 4 Kword x 16, 32 Kword x 126 sectors.
Bank A: 4 Kword x 8, 32 Kword x 15 sectors
Bank B: 32 Kword x 48 sectors
Bank C: 32 Kword x 48 sectors
Bank D: 4 Kword x 8, 32 Kword x 15 sectors
- **Cycling Endurance: 100,000 cycles per sector typical**
- **Data retention: 20-years typical**

Performance Characteristics

- **Read access times at 80/66 MHz**
 - Burst access times of 9.1/11.2 ns @ 30 pF at industrial temperature range
 - Synchronous latency of 46/56 ns (at 30 pF)

- Asynchronous random access times of 45/55 ns (at 30 pF)
- **Power dissipation (typical values, C_L = 30 pF)**
 - Burst Mode Read: 10 mA @ 80MHz
 - Simultaneous Operation: 25 mA @ 80MHz
 - Program/Erase: 15 mA
 - Standby mode: 0.2 μA

Hardware Features

- **Handshaking feature available**
 - Provides host system with minimum possible latency by monitoring RDY
- **Hardware reset input (RESET#)**
 - Hardware method to reset the device for reading array data
- **WP# input**
 - Write protect (WP#) function allows protection of four outermost boot sectors, regardless of sector protect status
- **Persistent Sector Protection**
 - A command sector protection method to lock combinations of individual sectors and sector groups to prevent program or erase operations within that sector
 - Sectors can be locked and unlocked in-system at V_{CC} level
- **Password Sector Protection**
 - A sophisticated sector protection method to lock combinations of individual sectors and sector groups to prevent program or erase operations within that sector using a user-defined 64-bit password
- **ACC input: Acceleration function reduces programming time; all sectors locked when ACC = V_{IL}**
- **CMOS compatible inputs, CMOS compatible outputs**
- **Low V_{CC} write inhibit**

Software Features

- **Supports Common Flash Memory Interface (CFI)**
- **Software command set compatible with JEDEC 42.4 standards**
 - Backwards compatible with AMD Am29BDS, AMD Am29BDD, AMD Am29BL, and Fujitsu MBM29BS families
- **Data# Polling and toggle bits**
 - Provides a software method of detecting program and erase operation completion

■ **Erase Suspend/Resume**

- Suspends an erase operation to read data from, or program data to, a sector that is not being erased, then resumes the erase operation

■ **Unlock Bypass Program command**

- Reduces overall programming time when issuing multiple program command sequences

General Description

The S29WS128/064J_MCP/S29WS064J is a 128/64 Mbit, 1.8 Volt-only, simultaneous Read/Write, Burst Mode Flash memory device, organized as 8,388,608/4,194,304 words of 16 bits each. This device uses a single V_{CC} of 1.65 to 1.95 V to read, program, and erase the memory array. A 12.0-volt V_{HH} on ACC may be used for faster program performance if desired. The device can also be programmed in standard EPROM programmers.

At 80 MHz, the device provides a burst access of 9.1 ns at 30 pF with a latency of 46 ns at 30 pF. At 66 MHz, the device provides a burst access of 11.2 ns at 30 pF with a latency of 56 ns at 30 pF. The device operates within the industrial temperature range of -40°C to +85°C and the wireless temperature range of -25°C to +85°C. The device is offered in Various FBGA packages.

The Simultaneous Read/Write architecture provides **simultaneous operation** by dividing the memory space into four banks. The device can improve overall system performance by allowing a host system to program or erase in one bank, then immediately and simultaneously read from another bank, with zero latency. This releases the system from waiting for the completion of program or erase operations.

The device is divided as shown in the following table:

| Bank | Quantity | | Size |
|------|----------|-------|-----------|
| | 128Mb | 64 Mb | |
| A | 8 | 8 | 4 Kwords |
| | 31 | 15 | 32 Kwords |
| B | 96 | 48 | 32 Kwords |
| C | 96 | 48 | 32 Kwords |
| D | 31 | 15 | 32 Kwords |
| | 8 | 8 | 4 Kwords |

The VersatileIO™ (V_{IO}) control allows the host system to set the voltage levels that the device generates at its data outputs and the voltages tolerated at its data inputs to the same voltage level that is asserted on the V_{IO} pin.

The device uses Chip Enable (CE#), Write Enable (WE#), Address Valid (AVD#) and Output Enable (OE#) to control asynchronous read and write operations. For burst operations, the device additionally requires Ready (RDY), and Clock (CLK). This implementation allows easy interface with minimal glue logic to a wide range of microprocessors/microcontrollers for high performance read operations.

The burst read mode feature gives system designers flexibility in the interface to the device. The user can preset the burst length and wrap through the same memory space, or read the flash array in continuous mode.

The clock polarity feature provides system designers a choice of active clock edges, either rising or falling. The active clock edge initiates burst accesses and determines when data will be output.

The device is entirely command set compatible with the **JEDEC 42.4 single-power-supply Flash standard**. Commands are written to the command register using standard microprocessor write timing. Register contents serve as inputs to an internal state-machine that controls the erase and programming circuitry. Write cycles also internally latch addresses and data needed for the programming and erase operations. Reading data out of the device is similar to reading from other Flash or EPROM devices.

The **Erase Suspend/Erase Resume** feature enables the user to put erase or program on hold for any period of time to read data from, or program data to, any sector that is not selected for erasure. True background erase can thus be achieved. If a read is needed from the Secured Silicon Sector area (One Time Program area) after an erase suspend, then the user must use the proper command sequence to enter and exit this region. Program suspend is also offered.

The **hardware RESET# pin** terminates any operation in progress and resets the internal state machine to reading array data. The RESET# pin may be tied to the system reset cir-

cuitry. A system reset would thus also reset the device, enabling the system microprocessor to read boot-up firmware from the Flash memory device.

The host system can detect whether a program or erase operation is complete by using the device status bit DQ7 (Data# Polling) and DQ6/DQ2 (toggle bits). After a program or erase cycle has been completed, the device automatically returns to reading array data.

The **sector erase architecture** allows memory sectors to be erased and reprogrammed without affecting the data contents of other sectors. The device is fully erased when shipped from the factory.

Hardware data protection measures include a low V_{CC} detector that automatically inhibits write operations during power transitions. The device also offers two types of data protection at the sector level. When at V_{IL} , **WP#** locks the four outermost boot sectors.

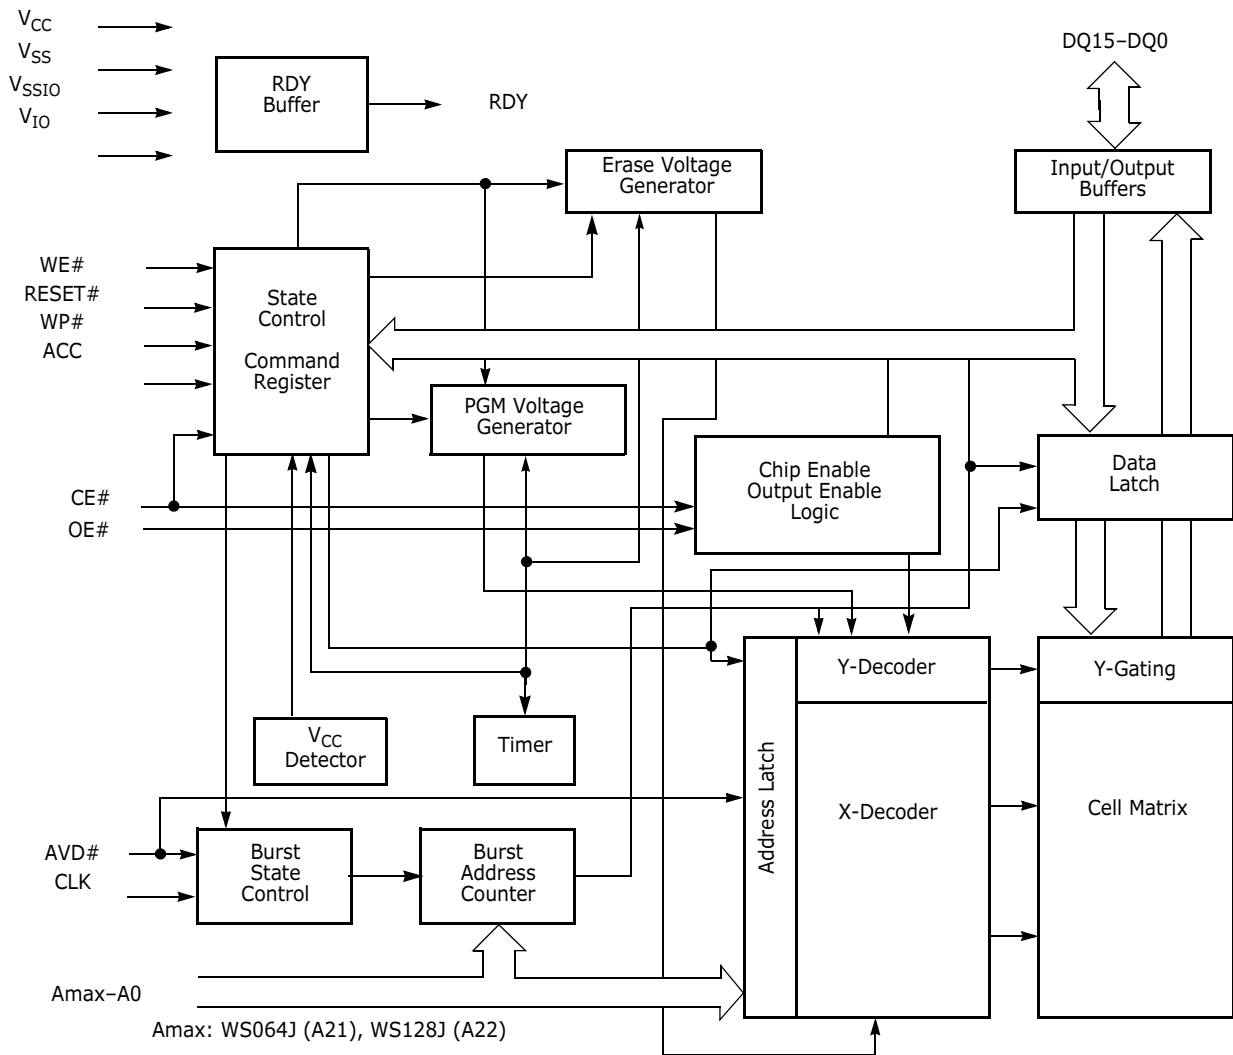

The device offers two power-saving features. When addresses have been stable for a specified amount of time, the device enters the **automatic sleep mode**. The system can also place the device into the **standby mode**. Power consumption is greatly reduced in both modes.

Spansion™ Flash memory products combine years of Flash memory manufacturing experience to produce the highest levels of quality, reliability and cost effectiveness. The device electrically erases all bits within a sector simultaneously via Fowler-Nordheim tunnelling. The data is programmed using hot electron injection.

Product Selector Guide

| Part Number | S29WS128/064J_MCP/S29WS064J | | | | | |
|---------------------------------|--|--------|----------|-----------------------------------|--------|----------|
| | Synchronous/Burst | | | Asynchronous | | |
| | Speed Option | 66 MHz | 80*2 MHz | Speed Option | 66 MHz | 80*2 MHz |
| $V_{IO} = 1.65 - 1.95\text{ V}$ | Max Latency, ns (t_{IACC}) | 56 | 46 | Max Access Time, ns (t_{ACC}) | 55 | 45 |
| | Max Burst Access Time, ns (t_{BACC}) | 11.2 | 9.1 | Max CE# Access, ns (t_{CE}) | 55 | 45 |
| | Max OE# Access, ns (t_{OE}) | 11.2 | 9.1 | Max OE# Access, ns (t_{OE}) | 11.2 | 9.1 |

Block Diagram

Block Diagram of Simultaneous Operation Circuit

Amax: WS064J (A21), WS128J (A22)

Input/Output Descriptions

| | | |
|-----------------|---|---|
| Amax-A0 | = | Address inputs |
| DQ15-DQ0 | = | Data input/output |
| CE# | = | Chip Enable input. Asynchronous relative to CLK for the Burst mode. |
| OE# | = | Output Enable input. Asynchronous relative to CLK for the Burst mode. |
| WE# | = | Write Enable input. |
| V _{CC} | = | Device Power Supply (1.65 – 1.95 V). |
| V _{IO} | = | Input & Output Buffer Power Supply (1.65 – 1.95 V). |
| V _{SS} | = | Ground |
| NC | = | No Connect; not connected internally |
| RDY | = | Ready output; In Synchronous Mode, indicates the status of the Burst read. Low = data not valid at expected time. High = data valid. In Asynchronous Mode, indicates the status of the internal program and erase function. Low = program/erase in progress. High Impedance = program/erase completed. |
| CLK | = | CLK is not required in asynchronous mode. In burst mode, after the initial word is output, subsequent active edges of CLK increment the internal address counter. |
| AVD# | = | Address Valid input. Indicates to device that the valid address is present on the address inputs (Amax-A0). Low = for asynchronous mode, indicates valid address; for burst mode, causes starting address to be latched. High = device ignores address inputs |
| RESET# | = | Hardware reset input. Low = device resets and returns to reading array data |
| WP# | = | Hardware write protect input. At V _{IL} , disables program and erase functions in the four outermost sectors. Should be at V _{IH} for all other conditions. |
| ACC | = | At V _{HH} , accelerates programming; automatically places device in unlock bypass mode. At V _{IL} , locks all sectors. Should be at V _{IH} for all other conditions. |

Note:

1. Amax = A22 (WS128J), A21 (WS064J)

Device Bus Operations

This section describes the requirements and use of the device bus operations, which are initiated through the internal command register. The command register itself does not occupy any addressable memory location. The register is composed of latches that store the commands, along with the address and data information needed to execute the command. The contents of the register serve as inputs to the internal state machine. The state machine outputs dictate the function of the device. Table 1 lists the device bus operations, the inputs and control levels they require, and the resulting output. The following subsections describe each of these operations in further detail.

Table 1. Device Bus Operations

| Operation | CE# | OE# | WE# | A22-0 | DQ15-0 | RESET# | CLK (See Note) | AVD# |
|---|-----|-----|-----|---------|----------------|--------|----------------------|------|
| Asynchronous Read - Addresses Latched | L | L | H | Addr In | I/O | H | X | |
| Asynchronous Read - Addresses Steady State | L | L | H | Addr In | I/O | H | X | L |
| Asynchronous Write | L | H | L | Addr In | I/O | H | X | L |
| Synchronous Write | L | H | L | Addr In | I/O | H | | |
| Standby (CE#) | H | X | X | HIGH Z | HIGH Z | H | X | X |
| Hardware Reset | X | X | X | HIGH Z | HIGH Z | L | X | X |
| Burst Read Operations | | | | | | | | |
| Load Starting Burst Address | L | X | H | Addr In | X | H | | |
| Advance Burst to next address with appropriate Data presented on the Data Bus | L | L | H | HIGH Z | Burst Data Out | H | | H |
| Terminate current Burst read cycle | H | X | H | HIGH Z | HIGH Z | H | | X |
| Terminate current Burst read cycle via RESET# | X | X | H | HIGH Z | HIGH Z | L | X | X |
| Terminate current Burst read cycle and start new Burst read cycle | L | X | H | HIGH Z | I/O | H | | |

Legend: L = Logic 0, H = Logic 1, X = Don't Care

Note: Default active edge of CLK is the rising edge.

VersatileIO™ (V_{IO}) Control

The VersatileIO (V_{IO}) control allows the host system to set the voltage levels that the device generates at its data outputs and the voltages tolerated at its data inputs to the same voltage level that is asserted on the V_{IO} pin.

Requirements for Asynchronous Read Operation (Non-Burst)

To read data from the memory array, the system must first assert a valid address on Amax-A0 (A22-A0 for WS128J and A21-A0 for WS064J), while driving AVD# and CE# to V_{IL}. WE# should remain at V_{IH}. The rising edge of AVD# latches the address. The data will appear on DQ15-DQ0. Since the memory array is divided into four banks, each bank remains enabled for read access until the command register contents are altered.

Address access time (t_{ACC}) is equal to the delay from stable addresses to valid output data. The chip enable access time (t_{CE}) is the delay from the stable ad-

dresses and stable CE# to valid data at the outputs. The output enable access time (t_{OE}) is the delay from the falling edge of OE# to valid data at the output.

The internal state machine is set for reading array data in asynchronous mode upon device power-up, or after a hardware reset. This ensures that no spurious alteration of the memory content occurs during the power transition.

Requirements for Synchronous (Burst) Read Operation

The device is capable of continuous sequential burst operation and linear burst operation of a preset length. When the device first powers up, it is enabled for asynchronous read operation.

Prior to entering burst mode, the system should determine how many wait states are desired for the initial word (t_{IACC}) of each burst access, what mode of burst operation is desired, which edge of the clock will be the active clock edge, and how the RDY signal will transition with valid data. The system would then write the configuration register command sequence. See "Set Configuration Register Command Sequence" section on page 62 and "Command Definitions" section on page 62 for further details.

Once the system has written the "Set Configuration Register" command sequence, the device is enabled for synchronous reads only.

The initial word is output t_{IACC} after the active edge of the first CLK cycle. Subsequent words are output t_{BACC} after the active edge of each successive clock cycle, which automatically increments the internal address counter. Note that the device has a fixed internal address boundary that occurs every 64 words, starting at address 00003Fh.

During the time the device is outputting data at this fixed internal address boundary (address 00003Fh, 00007Fh, 0000BFh, etc.), a two cycle latency occurs before data appears for the next address (address 000040h, 000080h, 0000C0h, etc.).

Additionally, when the device is read from an odd address, 1 wait state is inserted when the address pointer crosses the first boundary that occurs every 16 words. For instance, if the device is read from 00001Ah (odd), 1 wait state is inserted before the data of 000020h is output. This wait states is inserted at only the first 16 words boundary. Then, if the device is read from the odd address within the last 16 words of 64 word boundary (address 000031h, 000033h,..., 00003Eh), a three cycle latency occurs before data appears for the next address (address 000040h).

The RDY output indicates this condition to the system by pulsing deactive (low). See Figure 34, "Latency with Boundary Crossing," on page 109.

The device will continue to output sequential burst data, wrapping around to address 000000h after it reaches the highest addressable memory location, until the system drives CE# high, RESET# low, or AVD# low in conjunction with a new address. See Table 1, "Device Bus Operations," on page 25.

If the host system crosses the bank boundary while reading in burst mode, and the device is not programming or erasing, a two-cycle latency will occur as described above in the subsequent bank. If the host system crosses the bank boundary while the device is programming or erasing, the device will provide read status information. The clock will be ignored. After the host has completed status reads, or the device has completed the program or erase operation, the host can restart a burst operation using a new address and AVD# pulse.

8-, 16-, and 32-Word Linear Burst with Wrap Around

The remaining three burst read modes are of the linear wrap around design, in which a fixed number of words are read from consecutive addresses. In each of these modes, the burst addresses read are determined by the group within which the starting address falls. The groups are sized according to the number of words read in a single burst sequence for a given mode (see Table 2.)

Table 2. Burst Address Groups

| Mode | Group Size | Group Address Ranges |
|---------|------------|----------------------------|
| 8-word | 8 words | 0-7h, 8-Fh, 10-17h,... |
| 16-word | 16 words | 0-Fh, 10-1Fh, 20-2Fh,... |
| 32-word | 32 words | 00-1Fh, 20-3Fh, 40-5Fh,... |

As an example: if the starting address in the 8-word mode is 39h, the address range to be read would be 38-3Fh, and the burst sequence would be 39-3A-3B-3C-3D-3E-3F-38h-etc. The burst sequence begins with the starting address written to the device, but wraps back to the first address in the selected group. In a similar fashion, the 16-word and 32-word Linear Wrap modes begin their burst sequence on the starting address written to the device, and then wrap back to the first address in the selected address group. **Note that in these three burst read modes the address pointer does not cross the boundary that occurs every 128 or 64 words; thus, no wait states are inserted (except during the initial access).**

The RDY pin indicates when data is valid on the bus.

Configuration Register

The device uses a configuration register to set the various burst parameters: number of wait states, burst read mode, active clock edge, RDY configuration, and synchronous mode active.

Handshaking

The device is equipped with a handshaking feature that allows the host system to simply monitor the RDY signal from the device to determine when the initial word of burst data is ready to be read. The host system should use the programmable wait state configuration to set the number of wait states for optimal burst mode operation. The initial word of burst data is indicated by the active edge of RDY after OE# goes low.

For optimal burst mode performance, the host system must set the appropriate number of wait states in the flash device depending on clock frequency. See "Set Configuration Register Command Sequence" section on page 62 for more information.

Simultaneous Read/Write Operations with Zero Latency

This device is capable of reading data from one bank of memory while programming or erasing in another bank of memory. An erase operation may also be suspended to read from or program to another location within the same bank (except the sector being erased). Figure 37, "Back-to-Back Read/Write Cycle Timings," on page 112 shows how read and write cycles may be initiated for simultaneous operation with zero latency. Refer to the DC Characteristics table for read-while-program and read-while-erase current specifications.

Writing Commands/Command Sequences

The device has the capability of performing an asynchronous or synchronous write operation. While the device is configured in Asynchronous read mode, it is able to perform Asynchronous write operations only. CLK is ignored in the Asynchronous programming mode. When in the Synchronous read mode configuration, the device is able to perform both Asynchronous and Synchronous write operations. CLK and WE# address latch is supported in the Synchronous programming mode. During a synchronous write operation, to write a command or command sequence (which includes programming data to the device and erasing sectors of memory), the system must drive AVD# and CE# to V_{IL} , and OE# to V_{IH} when providing an address to the device, and drive WE# and CE# to V_{IL} , and OE# to V_{IH} when writing commands or data. During an asynchronous write operation, the system must drive CE# and WE# to V_{IL} and OE# to V_{IH} when providing an address, command, and data. Addresses are latched on the last falling edge of WE# or CE#, while data is latched on the 1st rising edge of WE# or CE#. The asynchronous and synchronous programming operation is independent of the Set Device Read Mode bit in the Configuration Register (see Table 17, "Configuration Register," on page 66).

The device features an Unlock Bypass mode to facilitate faster programming. Once the device enters the Unlock Bypass mode, only two write cycles are required to program a word, instead of four.

An erase operation can erase one sector, multiple sectors, or the entire device. Table 12, "WS128J Sector Address Table," on page 48 and Table 13, "WS064J Sector Address Table," on page 56 indicate the address space that each sector occupies. The device address space is divided into four banks. A "bank address" is the address bits required to uniquely select a bank. Similarly, a "sector address" is the address bits required to uniquely select a sector.

I_{CC2} in the "DC Characteristics" section on page 87 represents the active current specification for the write mode. The AC Characteristics section contains timing specification tables and timing diagrams for write operations.

Accelerated Program Operation

The device offers accelerated program operations through the ACC function. ACC is primarily intended to allow faster manufacturing throughput at the factory.

If the system asserts V_{HH} on this input, the device automatically enters the aforementioned Unlock Bypass mode and uses the higher voltage on the input to reduce the time required for program operations. The system would use a two-cycle program command sequence as required by the Unlock Bypass mode. Removing V_{HH} from the ACC input returns the device to normal operation. Note that sectors must be unlocked prior to raising ACC to V_{HH} . *Note that the ACC pin must not be at V_{HH} for operations other than accelerated programming, or device dam-*

age may result. In addition, the ACC pin must not be left floating or unconnected; inconsistent behavior of the device may result.

When at V_{IL} , ACC locks all sectors. ACC should be at V_{IH} for all other conditions.

Autoselect Mode

The autoselect mode provides manufacturer and device identification, and sector protection verification, through identifier codes output from the internal register (which is separate from the memory array) on DQ15–DQ0. This mode is primarily intended for programming equipment to automatically match a device to be programmed with its corresponding programming algorithm. However, the autoselect codes can also be accessed in-system through the command register.

When using programming equipment, the autoselect mode requires V_{ID} on address pin A9. Address pins must be as shown in Table 3, "Autoselect Codes (High Voltage Method)," on page 30. In addition, when verifying sector protection, the sector address must appear on the appropriate highest order address bits (see Table 4, "S29WS128/064J_MCP Boot Sector/Sector Block Addresses for Protection/Unprotection," on page 30 and Table 5, "S29WS064J Boot Sector/Sector Block Addresses for Protection/Unprotection," on page 32). Table 3 shows the remaining address bits that are don't care. When all necessary bits have been set as required, the programming equipment may then read the corresponding identifier code on DQ15–DQ0. However, the autoselect codes can also be accessed in-system through the command register, for instances when the device is erased or programmed in a system without access to high voltage on the A9 pin. The command sequence is illustrated in Table 18, "Command Definitions," on page 76. *Note that if a Bank Address (BA) on address bits A22, A21, and A20 for the WS128J (A21:A19 for the WS064J) is asserted during the third write cycle of the autoselect command, the host system can read autoselect data that bank and then immediately read array data from the other bank, without exiting the autoselect mode.*

To access the autoselect codes in-system, the host system can issue the autoselect command via the command register, as shown in Table 18, "Command Definitions," on page 76. This method does not require V_{ID} . Autoselect mode may only be entered and used when in the asynchronous read mode. Refer to the "Autoselect Command Sequence" section on page 67 for more information.

Table 3. Autoselect Codes (High Voltage Method)

| Description | CE# | OE# | WE # | RESET# | Amax to A12 | A11 to A10 | A9 | A8 | A7 | A6 | A5 to A4 | A3 | A2 | A1 | A0 | DQ15 to DQ0 |

Legend: L = Logic Low = V_{IL}, H = Logic High = V_{IH}, BA = Bank Address, SA = Sector Address, X = Don't care.

Notes:

1. The autoselect codes may also be accessed in-system via command sequences.
2. PPB Protection Status is shown on the data bus

Sector/Sector Block Protection and Unprotection

The hardware sector protection feature disables both programming and erase operations in any sector. The hardware sector unprotection feature re-enables both program and erase operations in previously protected sectors. Sector protection/unprotection can be implemented via two methods.

(Note: For the following discussion, the term "sector" applies to both sectors and sector blocks. A sector block consists of two or more adjacent sectors that are protected or unprotected at the same time (see Table 4, "S29WS128/064J_MCP Boot Sector/Sector Block Addresses for Protection/Unprotection," on page 30 and Table 5, "S29WS064J Boot Sector/Sector Block Addresses for Protection/Unprotection," on page 32).)

Sector Protection

The device features several levels of sector protection, which can disable both the program and erase operations in certain sectors or sector groups:

Persistent Sector Protection

A command sector protection method that replaces the old 12 V controlled protection method.

Password Sector Protection

A highly sophisticated protection method that requires a password before changes to certain sectors or sector groups are permitted

WP# Hardware Protection

A write protect pin that can prevent program or erase operations in the outermost sectors.

All parts default to operate in the Persistent Sector Protection mode. The customer must then choose if the Persistent or Password Protection method is most desirable. There are two one-time programmable non-volatile bits that define which sector protection method will be used. If the customer decides to continue using the Persistent Sector Protection method, they must set the **Persistent Sector Protection Mode Locking Bit**. This will permanently set the part to operate only using Persistent Sector Protection. If the customer decides to use the password method, they must set the **Password Mode Locking Bit**. This will permanently set the part to operate only using password sector protection.

It is important to remember that setting either the **Persistent Sector Protection Mode Locking Bit** or the **Password Mode Locking Bit** permanently selects the protection mode. It is not possible to switch between the two methods once a locking bit has been set. **It is important that one mode is explicitly selected when the device is first programmed, rather than relying on the default mode alone.** This is so that it is not possible for a system program or virus to later set the Password Mode Locking Bit, which would cause an unexpected shift from the default Persistent Sector Protection Mode into the Password Protection Mode.

The WP# Hardware Protection feature is always available, independent of the software managed protection method chosen.

The device is shipped with all sectors unprotected. Optional Spansion™ programming services enable programming and protecting sectors at the factory prior to shipping the device. Contact your local sales office for Details.

It is possible to determine whether a sector is protected or unprotected. See "Autoselect Command Sequence" section on page 67 for details.

Persistent Sector Protection

The Persistent Sector Protection method replaces the old 12 V controlled protection method while at the same time enhancing flexibility by providing three different sector protection states:

- **Persistently Locked**—A sector is protected and cannot be changed.
- **Dynamically Locked**—The sector is protected and can be changed by a simple command
- **Unlocked**—The sector is unprotected and can be changed by a simple command

In order to achieve these states, three types of "bits" are going to be used:

Persistent Protection Bit (PPB)

A single Persistent (non-volatile) Protection Bit is assigned to a maximum of four sectors ("S29WS128/064J_MCP Boot Sector/Sector Block Addresses for Protection/Unprotection" section on page 30, "S29WS064J Boot Sector/Sector Block Addresses for Protection/Unprotection" section on page 32). All 4 Kbyte boot-block sectors have individual sector Persistent Protection Bits (PPBs) for greater flexibility. Each PPB is individually modifiable through the **PPB Program Command**.

Note: If a PPB requires erasure, all of the sector PPBs must first be preprogrammed prior to PPB erasing. All PPBs erase in parallel, unlike programming where individual PPBs are programmable. It is the responsibility of the user to perform the preprogramming operation. Otherwise, an already erased sector PPBs has the potential of being over-erased. There is no hardware mechanism to prevent sector PPBs over-erasure.

Persistent Protection Bit Lock (PPB Lock)

A global volatile bit. When set to "1", the PPBs cannot be changed. When cleared ("0"), the PPBs are changeable. There is only one PPB Lock bit per device. The PPB Lock is cleared after power-up or hardware reset. There is no command sequence to unlock the PPB Lock.

Dynamic Protection Bit (DYB)

A volatile protection bit is assigned for each sector. After power-up or hardware reset, the contents of all DYBs is "0". Each DYB is individually modifiable through the DPB Write Command.

When the parts are first shipped, the PPBs are cleared ("0"). The DPBs and PPB Lock are defaulted to power up in the cleared state – meaning the PPBs are changeable.

When the device is first powered on, the DYBs power up in the cleared state (sectors not protected). The Protection State for each sector is determined by the logical OR of the PPB and the DPB related to that sector. For the sectors that have the PPBs cleared, the DPBs control whether or not the sector is protected or unprotected. By issuing the DPB Write command sequences, the DPBs will be set or cleared, thus placing each sector in the protected or unprotected state. These are the so-called **Dynamic Locked or Unlocked** states. They are called dynamic states because it is very easy to switch back and forth between the protected and unprotected conditions. This allows software to easily protect sectors against inadvertent changes yet does not prevent the easy removal of protection when changes are needed. The DPBs may be set or cleared as often as needed.

The PPBs allow for a more static, and difficult to change, level of protection. The PPBs retain their state across power cycles because they are Non-Volatile. Individual PPBs are set with a command but must all be cleared as a group through a complex sequence of program and erasing commands. The PPBs are also limited to 100 erase cycles.

The PPB Lock bit adds an additional level of protection. Once all PPBs are programmed to the desired settings, the PPB Lock may be set to "1". Setting the PPB Lock disables all program and erase commands to the Non-Volatile PPBs. In effect, the PPB Lock Bit locks the PPBs into their current state. The only way to clear the PPB Lock is to go through a power cycle. System boot code can determine if any changes to the PPB are needed e.g. to allow new system code to be

downloaded. If no changes are needed then the boot code can set the PPB Lock to disable any further changes to the PPBs during system operation.

The WP# write protect pin adds a final level of hardware protection to the four outermost 4 Kbytes sectors (SA0 - SA3 for a bottom boot, WS128J: SA266 - SA269, WS064J: SA138 - SA141, or SA0 - SA3 & WS128J: SA266 - SA269, WS064J: SA138 - SA141 for a dual boot). When this pin is low it is not possible to change the contents of these four sectors. These sectors generally hold system boot code. So, the WP# pin can prevent any changes to the boot code that could override the choices made while setting up sector protection during system initialization.

It is possible to have sectors that have been persistently locked, and sectors that are left in the dynamic state. The sectors in the dynamic state are all unprotected. If there is a need to protect some of them, a simple DPB Write command sequence is all that is necessary. The DPB write command for the dynamic sectors switch the DPBs to signify protected and unprotected, respectively. If there is a need to change the status of the persistently locked sectors, a few more steps are required. First, the PPB Lock bit must be disabled by either putting the device through a power-cycle, or hardware reset. The PPBs can then be changed to reflect the desired settings. Setting the PPB lock bit once again will lock the PPBs, and the device operates normally again.

Note: to achieve the best protection, it's recommended to execute the PPB lock bit set command early in the boot code, and protect the boot code by holding $WP\# = V_{IL}$.

Table 6. Sector Protection Schemes

| DPB | PPB | PPB Lock | Sector State |
|-----|-----|----------|---|
| 0 | 0 | 0 | Unprotected—PPB and DPB are changeable |
| 1 | 0 | 0 | Protected—PPB and DPB are changeable |
| 0 | 1 | 0 | Protected—PPB and DPB are changeable |
| 1 | 1 | 0 | Protected—PPB and DPB are changeable |
| 0 | 0 | 1 | Unprotected—PPB not changeable, DPB is changeable |
| 1 | 0 | 1 | Protected—PPB not changeable, DPB is changeable |
| 0 | 1 | 1 | Protected—PPB not changeable, DPB is changeable |
| 1 | 1 | 1 | Protected—PPB not changeable, DPB is changeable |

Table 6 contains all possible combinations of the DPB, PPB, and PPB lock relating to the status of the sector.

In summary, if the PPB is set, and the PPB lock is set, the sector is protected and the protection can not be removed until the next power cycle clears the PPB lock. If the PPB is cleared, the sector can be dynamically locked or unlocked. The DPB then controls whether or not the sector is protected or unprotected.

If the user attempts to program or erase a protected sector, the device ignores the command and returns to read mode. A program command to a protected sector enables status polling for approximately 1 μ s before the device returns to read mode without having modified the contents of the protected sector. An erase command to a protected sector enables status polling for approximately 50 μ s after which the device returns to read mode without having erased the protected sector.

The programming of the DPB, PPB, and PPB lock for a given sector can be verified by writing a DPB/PPB/PPB lock verify command to the device.

Persistent Sector Protection Mode Locking Bit

Like the password mode locking bit, a Persistent Sector Protection mode locking bit exists to guarantee that the device remain in software sector protection. Once set, the Persistent Sector Protection locking bit prevents programming of the password protection mode locking bit. This guarantees that a hacker could not place the device in password protection mode.

Password Protection Mode

The Password Sector Protection Mode method allows an even higher level of security than the Persistent Sector Protection Mode. There are two main differences between the Persistent Sector Protection and the Password Sector Protection Mode:

- When the device is first powered on, or comes out of a reset cycle, the PPB Lock bit is set to the **locked state**, rather than cleared to the unlocked state.
- The only means to clear the PPB Lock bit is by writing a unique **64-bit Password** to the device.

The Password Sector Protection method is otherwise identical to the Persistent Sector Protection method.

A 64-bit password is the only additional tool utilized in this method.

The password is stored in a the Secured Silicon region of the flash memory. Once the Password Mode Locking Bit is set, the password is permanently set with no means to read, program, or erase it. The password is used to clear the PPB Lock bit. The Password Unlock command must be written to the flash, along with a password. The flash device internally compares the given password with the pre-programmed password. If they match, the PPB Lock bit is cleared, and the PPBs can be altered. If they do not match, the flash device does nothing. There is a built-in 2 μ s delay for each "password check." This delay is intended to thwart any efforts to run a program that tries all possible combinations in order to crack the password.

Password and Password Mode Locking Bit

In order to select the Password sector protection scheme, the customer must first program the password. FASL recommends that the password be somehow correlated to the unique Electronic Serial Number (ESN) of the particular flash device. Each ESN is different for every flash device; therefore each password should be different for every flash device. While programming in the password region, the customer may perform Password Verify operations.

Once the desired password is programmed in, the customer must then set the Password Mode Locking Bit. This operation achieves two objectives:

1. It permanently sets the device to operate using the Password Protection Mode. It is not possible to reverse this function.
2. It also disables *all further commands* to the password region. All program, and read operations are ignored.

Both of these objectives are important, and if not carefully considered, may lead to unrecoverable errors. The user must be sure that the Password Protection method is desired when setting the Password Mode Locking Bit. More importantly, the user must be sure that the password is correct when the Password Mode Locking Bit is set. Due to the fact that read operations are disabled, there is no means to verify what the password is afterwards. If the password is lost after setting the Password Mode Locking Bit, there will be no way to clear the PPB Lock bit.

The Password Mode Locking Bit, once set, prevents reading the 64-bit password on the DQ bus and further password programming. The Password Mode Locking Bit is not erasable. Once Password Mode Locking Bit is programmed, the Persistent Sector Protection Locking Bit is disabled from programming, guaranteeing that no changes to the protection scheme are allowed.

64-bit Password

The 64-bit Password is located in its own memory space and is accessible through the use of the Password Program and Verify commands (see "Password Program Command" section on page 72 and "Password Verify Command" section on page 73). The password function works in conjunction with the Password Mode Locking Bit, which when set, prevents the Password Verify command from reading the contents of the password on the pins of the device.

Persistent Protection Bit Lock

The Persistent Protection Bit (PPB) Lock is a volatile bit that reflects the state of the Password Mode Locking Bit after power-up reset. If the Password Mode Lock Bit is also set, after a hardware reset (RESET# asserted) or a power-up reset the ONLY means for clearing the PPB Lock Bit in Password Protection Mode is to issue the Password Unlock command. Successful execution of the Password Unlock command clears the PPB Lock Bit, allowing for sector PPBs modifications. Asserting RESET#, taking the device through a power-on reset, or issuing the PPB Lock Bit Set command sets the PPB Lock Bit to a "1".

If the Password Mode Locking Bit is not set, including Persistent Protection Mode, the PPB Lock Bit is cleared after power-up or hardware reset. The PPB Lock Bit is settable by issuing the PPB Lock Bit Set command. Once set the only means for clearing the PPB Lock Bit is by issuing a hardware or power-up reset. The Password Unlock command is ignored in Persistent Protection Mode.

High Voltage Sector Protection

Sector protection and unprotection may also be implemented using programming equipment. The procedure requires high voltage (VID) to be placed on the RESET# pin. Refer to Figure 2, "In-System Sector Protection/Sector Unprotection Algorithms," on page 41 for details on this procedure. Note that for sector unprotect, all unprotected sectors must be first protected prior to the first sector write cycle. Once the Password Mode Locking bit or Persistent Protection Locking bit are set, the high voltage sector protect/unprotect capability is disabled.

Standby Mode

When the system is not reading or writing to the device, it can place the device in the standby mode. In this mode, current consumption is greatly reduced, and the outputs are placed in the high impedance state, independent of the OE# input.

The device enters the CMOS standby mode when the CE# and RESET# inputs are both held at $V_{CC} \pm 0.2$ V. The device requires standard access time (t_{CE}) for read access, before it is ready to read data.

If the device is deselected during erasure or programming, the device draws active current until the operation is completed.

I_{CC3} in the "DC Characteristics" section on page 87 represents the standby current specification.

Automatic Sleep Mode

The automatic sleep mode minimizes Flash device energy consumption. While in asynchronous mode, the device automatically enables this mode when addresses remain stable for $t_{ACC} + 60$ ns. The automatic sleep mode is independent of the CE#, WE#, and OE# control signals. Standard address access timings provide new data when addresses are changed. While in sleep mode, output data is latched and always available to the system. **Based on the implementation by design, the Auto Power Down feature is disabled in synchronous mode and enabled in asynchronous mode. As a result, in synchronous mode, the device can be in Auto Power Down Mode only by deselecting the CE#.** Note that a new burst operation is required to provide new data.

I_{CC6} in the "DC Characteristics" section on page 87 represents the automatic sleep mode current specification.

RESET#: Hardware Reset Input

The RESET# input provides a hardware method of resetting the device to reading array data. When RESET# is driven low for at least a period of t_{RP} , the device immediately terminates any operation in progress, tristates all outputs, resets the configuration register, and ignores all read/write commands for the duration of the RESET# pulse. The device also resets the internal state machine to reading array data. The operation that was interrupted should be reinitiated once the device is ready to accept another command sequence, to ensure data integrity.

Current is reduced for the duration of the RESET# pulse. When RESET# is held at $V_{SS} \pm 0.2$ V, the device draws CMOS standby current (I_{CC4}). If RESET# is held at V_{IL} but not within $V_{SS} \pm 0.2$ V, the standby current will be greater.

RESET# may be tied to the system reset circuitry. A system reset would thus also reset the Flash memory, enabling the system to read the boot-up firmware from the Flash memory.

If RESET# is asserted during a program or erase operation, the device requires a time of t_{READY} (during Embedded Algorithms) before the device is ready to read data again. If RESET# is asserted when a program or erase operation is not executing, the reset operation is completed within a time of t_{READY} (not during Embedded Algorithms). The system can read data t_{RH} after RESET# returns to V_{IH} .

Refer to the "AC Characteristics" section on page 97 for RESET# parameters and to Figure 21, "Reset Timings," on page 97 for the timing diagram.

Output Disable Mode

When the OE# input is at V_{IH} , output from the device is disabled. The outputs are placed in the high impedance state.

Notes:

1. All protected sectors unprotected (If $WP# = V_{IL}$, outermost boot sectors will remain protected).
2. All previously protected sectors are protected once again.

Figure I. Temporary Sector Unprotect Operation

Figure 2. In-System Sector Protection/Sector Unprotection Algorithms

Secured Silicon Sector Flash Memory Region

The Secured Silicon Sector feature provides a Flash memory region that enables permanent part identification through an Electronic Serial Number (ESN). The Secured Silicon Sector is 128 words in length and located at addresses 000000h-000007h. The Factory Indicator Bit (DQ7) is used to indicate whether or not the Factory Secured Silicon Sector is locked when shipped from the factory. The Customer Indicator Bit (DQ6) is used to indicate whether or not the Customer Secured Silicon Sector is locked when shipped from the factory. These bits are permanently set at the factory and cannot be changed, in order to prevent cloning of a factory locked part. This ensures the security of the ESN and customer code once the product is shipped to the field.

FASL™ offers the device with a 64 word Factory Secured Silicon Sector that is locked when the part is shipped and a 64 words Customer Secured Silicon Sector that is either locked or is lockable. The Factory Secured Silicon Sector is always protected when shipped from the factory, and has the Factory Indicator Bit (DQ7) permanently set to a "1". The Customer Secured Silicon Sector is shipped unprotected with the Customer Indicator Bit (DQ6) set to "0", allowing customers to utilize that sector in any manner they choose. Once the Customer Secured Silicon Sector area is protected, the Customer Indicator Bit will be permanently set to "1."

The system accesses the Secured Silicon Sector through a command sequence (see "Enter/Exit Secured Silicon Sector Command Sequence"). After the system has written the Enter Secured Silicon Sector command sequence, it may read the Secured Silicon Sector by using the addresses normally occupied by the memory array. This mode of operation continues until the system issues the Exit Secured Silicon Sector command sequence, or until power is removed from the device. While Secured Silicon Sector access is enabled, Memory Array read access, program operations, and erase operations to all sectors other than SA0 are also available. On power-up, or following a hardware reset, the device reverts to sending commands to the normal address space.

Factory Locked: Factor Secured Silicon Sector Programmed and Protected At the Factory

In a factory sector locked device, the Factory Secured Silicon Sector is protected when the device is shipped from the factory whether or not the area was programmed at the factory. The Factory Secured Silicon Sector cannot be modified in any way. Optional Spansion™ programming service can preprogram a random ESN, a customer-defined code, or any combination of the two. The Factory Secured Silicon Sector is located at addresses 000000h-00003Fh.

The device is available preprogrammed with one of the following:

- A random, secure ESN only within the Factor Secured Silicon Sector
- Customer code within the Customer Secured Silicon Sector through the Spansion programming service
- Both a random, secure ESN and customer code through the Spansion programming service.

Table 7. Secured Silicon Sector Addresses

| Sector | Sector Size | Address Range |
|----------|-------------|-----------------|
| Customer | 64 words | 000040h-00007Fh |
| Factory | 64 words | 000000h-00003Fh |

Customers may opt to have their code programmed by FASL through the Spansion programming service. FASL programs the customer's code, with or without the random ESN. The devices are then shipped from FASL's factory with the Factory Secured Silicon Sector and Customer Secured Silicon Sector permanently locked. Contact the local sales office for details on using Spansion programming services.

Customer Secured Silicon Sector

The customer lockable area is shipped unprotected, which allows the customer to program and optionally lock the area as appropriate for the application. security feature is not required, the Customer Secured Silicon Sector can be treated as an additional Flash memory space. The Customer Secured Silicon Sector can be read any number of times, but can be programmed and locked only once. Note that the accelerated programming (ACC) and unlock bypass functions are not available when programming the Customer Secured Silicon Sector, but reading in Banks A, B, and C is available. The Customer Secured Silicon Sector is located at addresses 000040h–00007Fh.

The Customer Secured Silicon Sector area can be protected using one of the following procedures:

- Write the three-cycle Enter Secured Silicon Sector Region command sequence, and then follow the in-system sector protect algorithm as shown in Figure 2, "In-System Sector Protection/Sector Unprotection Algorithms," on page 41 except that *RESET#* may be at either V_{IH} or V_{ID} . This allows in-system protection of the Customer Secured Silicon Sector Region without raising any device pin to a high voltage. Note that this method is only applicable to the Secured Silicon Sector.
- Write the Secured Silicon Sector Protection Bit Lock command sequence.

Once the Customer Secured Silicon Sector is locked and verified, the system must write the Exit Secured Silicon Sector Region command sequence to return to reading and writing the remainder of the array.

The Customer Secured Silicon Sector lock must be used with caution since, once locked, there is no procedure available for unlocking the Customer Secured Silicon Sector area and none of the bits in the Customer Secured Silicon Sector memory space can be modified in any way.

Secured Silicon Sector Protection Bit

The Customer Secured Silicon Sector Protection Bit prevents programming of the Customer Secured Silicon Sector memory area. Once set, the Customer Secured Silicon Sector memory area contents are non-modifiable.

Hardware Data Protection

The command sequence requirement of unlock cycles for programming or erasing provides data protection against inadvertent writes (refer to Table 18, "Command Definitions," on page 76 for command definitions).

The device offers two types of data protection at the sector level:

- The PPB and DPB associated command sequences disables or re-enables both program and erase operations in any sector or sector group.
- When $WP\#$ is at V_{IL} , the four outermost sectors are locked.
- When ACC is at V_{IL} , all sectors are locked.

The following hardware data protection measures prevent accidental erasure or programming, which might otherwise be caused by spurious system level signals during V_{CC} power-up and power-down transitions, or from system noise.

Write Protect (WP#)

The Write Protect feature provides a hardware method of protecting the four outermost sectors. This function is provided by the WP# pin and overrides the previously discussed Sector Protection/Unprotection method.

If the system asserts V_{IL} on the WP# pin, the device disables program and erase functions in the four "outermost" 4 Kword boot sectors. The four outermost 4 Kword boot sectors are the four sectors containing the lowest addresses (SA0 - SA3), or the four sectors containing the highest addresses (WS128J: SA266 - SA269, WS064J: SA138 - SA141) or both the lower four (SA0 - SA3) and upper four sectors (WS128J: SA266 - SA269, WS064J: SA138 - SA141) in a dual-boot-configured device.

If the system asserts V_{IH} on the WP# pin, the device reverts to whether the upper and/or lower four sectors were last set to be protected or unprotected. That is, sector protection or unprotection for these sectors depends on whether they were last protected or unprotected using the method described in "PPB Program Command" section on page 75.

Note that the WP# pin must not be left floating or unconnected; inconsistent behavior of the device may result.

Low V_{CC} Write Inhibit

When V_{CC} is less than V_{LKO} , the device does not accept any write cycles. This protects data during V_{CC} power-up and power-down. The command register and all internal program/erase circuits are disabled, and the device resets to reading array data. Subsequent writes are ignored until V_{CC} is greater than V_{LKO} . The system must provide the proper signals to the control inputs to prevent unintentional writes when V_{CC} is greater than V_{LKO} .

Write Pulse "Glitch" Protection

Noise pulses of less than 5 ns (typical) on OE#, CE# or WE# do not initiate a write cycle.

Logical Inhibit

Write cycles are inhibited by holding any one of OE# = V_{IL} , CE# = V_{IH} or WE# = V_{IH} . To initiate a write cycle, CE# and WE# must be a logical zero while OE# is a logical one.

Power-Up Write Inhibit

If WE# = CE# = RESET# = V_{IL} and OE# = V_{IH} during power up, the device does not accept commands on the rising edge of WE#. The internal state machine is automatically reset to the read mode on power-up.

Common Flash Memory Interface (CFI)

The Common Flash Interface (CFI) specification outlines device and host system software interrogation handshake, which allows specific vendor-specified software algorithms to be used for entire families of devices. Software support can then be device-independent, JEDEC ID-independent, and forward- and backward-compatible for the specified flash device families. Flash vendors can standardize their existing interfaces for long-term compatibility.

This device enters the CFI Query mode when the system writes the CFI Query command, 98h, to address 55h any time the device is ready to read array data. The system can read CFI information at the addresses given in Tables 8-11. To terminate reading CFI data, the system must write the reset command.

The system can also write the CFI query command when the device is in the autoselect mode. The device enters the CFI query mode, and the system can read CFI data at the addresses given in Tables 8-11. The system must write the reset command to return the device to the autoselect mode.

For further information, please refer to the CFI Specification and CFI Publication 100, available via the FASL site at the following URL:

http://www.amd.com/us-en/FlashMemory/TechnicalResources/0,,37_1693_1780_1834^1955,00.html. Alternatively, contact an FASL representative for copies of these documents.

Table 8. CFI Query Identification String

| Addresses | Data | Description |

Command Definitions

Writing specific address and data commands or sequences into the command register initiates device operations. Table 18, "Command Definitions," on page 76 defines the valid register command sequences. Writing incorrect address and data values or writing them in the improper sequence may place the device in an unknown state. The system must write the reset command to return the device to reading array data. Refer to the AC Characteristics section for timing diagrams.

Reading Array Data

The device is automatically set to reading array data after device power-up. No commands are required to retrieve data in asynchronous mode. Each bank is ready to read array data after completing an Embedded Program or Embedded Erase algorithm.

After the device accepts an Erase Suspend command, the corresponding bank enters the erase-suspend-read mode, after which the system can read data from any non-erase-suspended sector within the same bank. After completing a programming operation in the Erase Suspend mode, the system may once again read array data from any non-erase-suspended sector within the same bank. See the "Erase Suspend/Erase Resume Commands" section on page 71 for more information.

The system must issue the reset command to return a bank to the read (or erase-suspend-read) mode if DQ5 goes high during an active program or erase operation, or if the bank is in the autoselect mode. See the "Reset Command" section on page 66 for more information.

See also "Requirements for Asynchronous Read Operation (Non-Burst)" section on page 25 and "Requirements for Synchronous (Burst) Read Operation" section on page 26 for more information. The Asynchronous Read and Synchronous/Burst Read tables provide the read parameters, and Figure 14, "CLK Synchronous Burst Mode Read (rising active CLK)," on page 92, Figure 16, "Synchronous Burst Mode Read," on page 93, and Figure 19, "Asynchronous Mode Read with Latched Addresses," on page 96 show the timings.

Set Configuration Register Command Sequence

The device uses a configuration register to set the various burst parameters: number of wait states, burst read mode, active clock edge, RDY configuration, and synchronous mode active. The configuration register must be set before the device will enter burst mode.

The configuration register is loaded with a three-cycle command sequence. The first two cycles are standard unlock sequences. On the third cycle, the data should be C0h, address bits A11–A0 should be 555h, and address bits A19–A12 set the code to be latched. The device will power up or after a hardware reset with the default setting, which is in asynchronous mode. The register must be set before the device can enter synchronous mode. The configuration register can not be changed during device operations (program, erase, or sector lock).

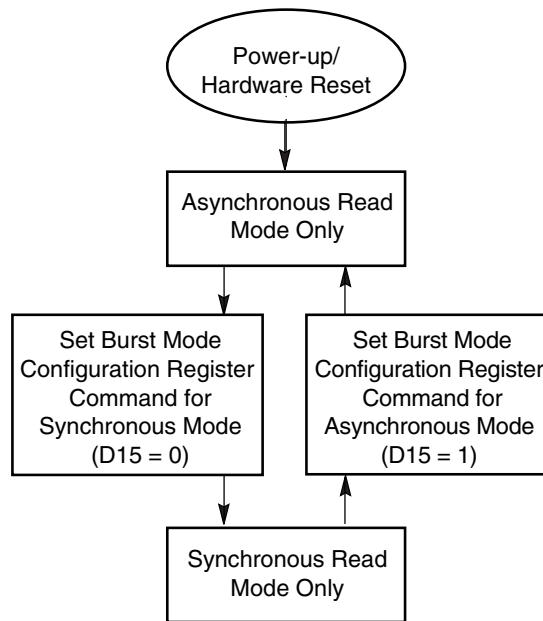

Figure 3. Synchronous/Asynchronous State Diagram

Read Mode Setting

On power-up or hardware reset, the device is set to be in asynchronous read mode. This setting allows the system to enable or disable burst mode during system operations. Address A19 determines this setting: "1" for asynchronous mode, "0" for synchronous mode.

Programmable Wait State Configuration

The programmable wait state feature informs the device of the number of clock cycles that must elapse after $AVD\#$ is driven active before data will be available. This value is determined by the input frequency of the device. Address bits A14–A12 determine the setting (see Table 14, "Programmable Wait State Settings," on page 64).

The wait state command sequence instructs the device to set a particular number of clock cycles for the initial access in burst mode. The number of wait states that should be programmed into the device is directly related to the clock frequency.

Table I4. Programmable Wait State Settings

| A14 | A13 | A12 | Total Initial Access Cycles |
|-----|-----|-----|-----------------------------|
| 0 | 0 | 0 | 2 |
| 0 | 0 | 1 | 3 |
| 0 | 1 | 0 | 4 |
| 0 | 1 | 1 | 5 |
| 1 | 0 | 0 | 6 |
| 1 | 0 | 1 | 7 (default) |
| 1 | 1 | 0 | Reserved |
| 1 | 1 | 1 | Reserved |

Notes:

1. Upon power-up or hardware reset, the default setting is seven wait states.
2. RDY will default to being active with data when the Wait State Setting is set to a total initial access cycle of 2.

It is recommended that the wait state command sequence be written, even if the default wait state value is desired, to ensure the device is set as expected. A hardware reset will set the wait state to the default setting.

Standard wait-state Handshaking Option

The host system must set the appropriate number of wait states in the flash device depending upon the clock frequency. The host system should set address bits A14–A12 to 010 for a clock frequency of 66/80 MHz.

Table 15 describes the typical number of clock cycles (wait states) for various conditions.

Table 15. Wait States for Standard wait-state Handshaking

| Burst Mode | Conditions | Typical No. of Clock Cycles after AVD# Low |
|---------------------------------|------------------|--|
| | | 66/80 MHz |
| 8-Word or 16-Word or Continuous | $V_{IO} = 1.8 V$ | 4 |
| 32-Word | $V_{IO} = 1.8 V$ | 5 |

* In the 8-, 16- and 32-word burst read modes, the address pointer does not cross 64-word boundaries (addresses which are multiples of 3Fh).

The host system must set the appropriate number of wait states in the flash device depending upon the clock frequency. The autoselect function allows the host system to determine whether the flash device is enabled for handshaking. See the "Autoselect Command Sequence" section on page 67 for more information.

Read Mode Configuration

The device supports four different read modes: continuous mode, and 8, 16, and 32 word linear wrap around modes. A continuous sequence begins at the starting address and advances the address pointer until the burst operation is complete. If the highest address in the device is reached during the continuous burst read mode, the address pointer wraps around to the lowest address.

For example, an eight-word linear read with wrap around begins on the starting address written to the device and then advances to the next 8 word boundary. The address pointer then returns to the 1st word after the previous eight word boundary, wrapping through the starting location. The sixteen- and thirty-two linear wrap around modes operate in a fashion similar to the eight-word mode.

Table 16 shows the address bits and settings for the four read modes.

Table 16. Read Mode Settings

| Burst Modes | Address Bits | |
|----------------------------|--------------|-----|
| | A16 | A15 |
| Continuous | 0 | 0 |
| 8-word linear wrap around | 0 | 1 |
| 16-word linear wrap around | 1 | 0 |
| 32-word linear wrap around | 1 | 1 |

Note: Upon power-up or hardware reset the default setting is continuous.

Burst Active Clock Edge Configuration

By default, the device will deliver data on the rising edge of the clock after the initial synchronous access time. Subsequent outputs will also be on the following rising edges, barring any delays. The device can be set so that the falling clock edge is active for all synchronous accesses. Address bit A17 determines this setting; "1" for rising active, "0" for falling active.

RDY Configuration

By default, the device is set so that the RDY pin will output V_{OH} whenever there is valid data on the outputs. The device can be set so that RDY goes active one data cycle before active data. Address bit A18 determines this setting; "1" for RDY active with data, "0" for RDY active one clock cycle before valid data. In asynchronous mode, RDY is an open-drain output.

Configuration Register

Table 17 shows the address bits that determine the configuration register settings for various device functions.

Table 17. Configuration Register

| Address Bit | Function | Settings (Binary) |
|-------------|-------------------------|--|
| A19 | Set Device Read Mode | 0 = Synchronous Read (Burst Mode) Enabled 1 = Asynchronous Mode (default) |
| A18 | RDY | 0 = RDY active one clock cycle before data 1 = RDY active with data (default) |
| A17 | Clock | 0 = Burst starts and data is output on the falling edge of CLK 1 = Burst starts and data is output on the rising edge of CLK (default) |
| A16 | Read Mode | Synchronous Mode |
| A15 | | 00 = Continuous (default) 01 = 8-word linear with wrap around 10 = 16-word linear with wrap around 11 = 32-word linear with wrap around |
| A14 | Programmable Wait State | 000 = Data is valid on the 2nd active CLK edge after AVD# transition to V_{IH} |
| A13 | | 001 = Data is valid on the 3rd active CLK edge after AVD# transition to V_{IH} |
| A12 | | 010 = Data is valid on the 4th active CLK edge after AVD# transition to V_{IH} 011 = Data is valid on the 5th active CLK edge after AVD# transition to V_{IH} 100 = Data is valid on the 6th active CLK edge after AVD# transition to V_{IH} 101 = Data is valid on the 7th active CLK edge after AVD# transition to V_{IH} (default) 110 = Reserved 111 = Reserved |

Note: Device will be in the default state upon power-up or hardware reset.

Reset Command

Writing the reset command resets the banks to the read or erase-suspend-read mode. Address bits are don't cares for this command.

The reset command may be written between the sequence cycles in an erase command sequence before erasing begins. This resets the bank to which the system was writing to the read mode. Once erasure begins, however, the device ignores reset commands until the operation is complete.

The reset command may be written between the sequence cycles in a program command sequence before programming begins (prior to the third cycle). This resets the bank to which the system was writing to the read mode. If the program command sequence is written to a bank that is in the Erase Suspend mode, writing the reset command returns that bank to the erase-suspend-read mode. Once programming begins, however, the device ignores reset commands until the operation is complete.

The reset command may be written between the sequence cycles in an autoselect command sequence. Once in the autoselect mode, the reset command must be written to return to the read mode. If a bank entered the autoselect mode while in the Erase Suspend mode, writing the reset command returns that bank to the erase-suspend-read mode.

If DQ5 goes high during a program or erase operation, writing the reset command returns the banks to the read mode (or erase-suspend-read mode if that bank was in Erase Suspend).

Autoselect Command Sequence

The autoselect command sequence allows the host system to access the manufacturer and device codes, and determine whether or not a sector is protected. Table 18, "Command Definitions," on page 76 shows the address and data requirements. The autoselect command sequence may be written to an address within a bank that is either in the read or erase-suspend-read mode. The autoselect command may not be written while the device is actively programming or erasing in the other bank.

The autoselect command sequence is initiated by first writing two unlock cycles. This is followed by a third write cycle that contains the bank address and the autoselect command. The bank then enters the autoselect mode. No subsequent data will be made available if the autoselect data is read in synchronous mode. The system may read at any address within the same bank any number of times without initiating another autoselect command sequence. Read commands to other banks will return data from the array. The following table describes the address requirements for the various autoselect functions, and the resulting data. BA represents the bank address, and SA represents the sector address. The device ID is read in three cycles.

| Description | Address | Read Data |
|--------------------------------|------------|---|
| Manufacturer ID | (BA) + 00h | 0001h |
| Device ID, Word 1 | (BA) + 01h | 227Eh |
| Device ID, Word 2 | (BA) + 0Eh | 2218h (WS128J) 221Eh (WS064J) |
| Device ID, Word 3 | (BA) + 0Fh | 2200h (WS128J) 2201h (WS064J) |
| Sector Protection Verification | (SA) + 02h | 0001 (locked), 0000 (unlocked) |
| Indicator Bits | (BA) + 03h | DQ15 - DQ8 = 0 DQ7 - Factory Lock Bit 1 = Locked, 0 = Not Locked DQ6 - Customer Lock Bit 1 = Locked, 0 = Not Locked DQ5 - Handshake Bit 1 = Reserved, 0 = Standard Handshake DQ4 & DQ3 - Boot Code 00 = Dual Boot Sector, 01 = Top Boot Sector, 10 = Bottom Boot Sector DQ2 - DQ0 = 001 |

The system must write the reset command to return to the read mode (or erase-suspend-read mode if the bank was previously in Erase Suspend).

Enter/Exit Secured Silicon Sector Command Sequence

The Secured Silicon Sector region provides a secured data area containing a random, eight word electronic serial number (ESN). The system can access the

Secured Silicon Sector region by issuing the three-cycle Enter Secured Silicon Sector command sequence. The device continues to access the Secured Silicon Sector region until the system issues the four-cycle Exit Secured Silicon Sector command sequence. The Exit Secured Silicon Sector command sequence returns the device to normal operation. The Secured Silicon Sector is not accessible when the device is executing an Embedded Program or embedded Erase algorithm. Table 18, "Command Definitions," on page 76 shows the address and data requirements for both command sequences.

The following commands are not allowed when the Secured Silicon is accessible.

- CFI
- Unlock Bypass Entry
- Unlock Bypass Program
- Unlock Bypass Reset
- Erase Suspend/Resume
- Chip Erase

Program Command Sequence

Programming is a four-bus-cycle operation. The program command sequence is initiated by writing two unlock write cycles, followed by the program set-up command. The program address and data are written next, which in turn initiate the Embedded Program algorithm. The system is not required to provide further controls or timings. The device automatically provides internally generated program pulses and verifies the programmed cell margin. Table 18, "Command Definitions," on page 76 shows the address and data requirements for the program command sequence.

When the Embedded Program algorithm is complete, that bank then returns to the read mode and addresses are no longer latched. The system can determine the status of the program operation by monitoring DQ7 or DQ6/DQ2. Refer to the "Write Operation Status" section on page 79 for information on these status bits.

Any commands written to the device during the Embedded Program Algorithm are ignored. Note that a hardware reset immediately terminates the program operation. The program command sequence should be reinitiated once that bank has returned to the read mode, to ensure data integrity.

Programming is allowed in any sequence and across sector boundaries. A bit cannot be programmed from "0" back to a "1." Attempting to do so may cause that bank to set DQ5 = 1, or cause the DQ7 and DQ6 status bit to indicate the operation was successful. However, a succeeding read will show that the data is still "0." Only erase operations can convert a "0" to a "1."

Unlock Bypass Command Sequence

The unlock bypass feature allows the system to primarily program to a array faster than using the standard program command sequence. The unlock bypass command sequence is initiated by first writing two unlock cycles. This is followed by a third write cycle containing the unlock bypass command, 20h. The device then enters the unlock bypass mode. A two-cycle unlock bypass program command sequence is all that is required to program in this mode. The first cycle in this sequence contains the unlock bypass program command, A0h; the second cycle contains the program address and data. Additional data is programmed in the same manner. This mode dispenses with the initial two unlock cycles required in the standard program command sequence, resulting in faster total programming time. The host system may also initiate the chip erase and sector erase

sequences in the unlock bypass mode. The erase command sequences are four cycles in length instead of six cycles. Table 18, "Command Definitions," on page 76 shows the requirements for the unlock bypass command sequences.

During the unlock bypass mode, only the Read, Unlock Bypass Program, Unlock Bypass Sector Erase, Unlock Bypass Chip Erase, and Unlock Bypass Reset commands are valid. To exit the unlock bypass mode, the system must issue the two-cycle unlock bypass reset command sequence. The first cycle must contain the bank address and the data 90h. The second cycle need only contain the data 00h. The array then returns to the read mode.

The device offers accelerated program operations through the ACC input. When the system asserts V_{HH} on this input, the device automatically enters the Unlock Bypass mode. The system may then write the two-cycle Unlock Bypass program command sequence. The device uses the higher voltage on the ACC input to accelerate the operation.

Figure 4, "Program Operation," on page 69 illustrates the algorithm for the program operation. Refer to the Erase/Program Operations table in the AC Characteristics section for parameters, and Figure 22, "Asynchronous Program Operation Timings: AVD# Latched Addresses," on page 99 and Figure 24, "Synchronous Program Operation Timings: WE# Latched Addresses," on page 101 for timing diagrams.

Note: See Table 18 for program command sequence.

Figure 4. Program Operation

Chip Erase Command Sequence

Chip erase is a six bus cycle operation. The chip erase command sequence is initiated by writing two unlock cycles, followed by a set-up command. Two

additional unlock write cycles are then followed by the chip erase command, which in turn invokes the Embedded Erase algorithm. The device does not require the system to preprogram prior to erase. The Embedded Erase algorithm automatically preprograms and verifies the entire memory for an all zero data pattern prior to electrical erase. The system is not required to provide any controls or timings during these operations. Table 18, "Command Definitions," on page 76 shows the address and data requirements for the chip erase command sequence.

When the Embedded Erase algorithm is complete, that bank returns to the read mode and addresses are no longer latched. The system can determine the status of the erase operation by using DQ7 or DQ6/DQ2. Refer to the "Write Operation Status" section on page 79 for information on these status bits.

Any commands written during the chip erase operation are ignored. However, note that a **hardware reset** immediately terminates the erase operation. If that occurs, the chip erase command sequence should be reinitiated once that bank has returned to reading array data, to ensure data integrity.

The host system may also initiate the chip erase command sequence while the device is in the unlock bypass mode. The command sequence is two cycles in length instead of six cycles. See Table 18, "Command Definitions," on page 76 for details on the unlock bypass command sequences.

Figure 5, "Erase Operation," on page 72 illustrates the algorithm for the erase operation. Refer to the Erase/Program Operations table in the AC Characteristics section for parameters and timing diagrams.

Sector Erase Command Sequence

Sector erase is a six bus cycle operation. The sector erase command sequence is initiated by writing two unlock cycles, followed by a set-up command. Two additional unlock cycles are written, and are then followed by the address of the sector to be erased, and the sector erase command. Table 18, "Command Definitions," on page 76 shows the address and data requirements for the sector erase command sequence.

The device does not require the system to preprogram prior to erase. The Embedded Erase algorithm automatically programs and verifies the entire memory for an all zero data pattern prior to electrical erase. The system is not required to provide any controls or timings during these operations.

After the command sequence is written, a sector erase time-out of no less than 50 μ s occurs. During the time-out period, additional sector addresses and sector erase commands may be written. Loading the sector erase buffer may be done in any sequence, and the number of sectors may be from one sector to all sectors. The time between these additional cycles must be less than 50 μ s, otherwise erasure may begin. Any sector erase address and command following the exceeded time-out may or may not be accepted. It is recommended that processor interrupts be disabled during this time to ensure all commands are accepted. The interrupts can be re-enabled after the last Sector Erase command is written. Any command other than Sector Erase or Erase Suspend during the time-out period resets that bank to the read mode. The system must rewrite the command sequence and any additional addresses and commands.

The system can monitor DQ3 to determine if the sector erase timer has timed out (See "DQ3: Sector Erase Timer" section on page 84.) The time-out begins from the rising edge of the final WE# pulse in the command sequence.

When the Embedded Erase algorithm is complete, the bank returns to reading array data and addresses are no longer latched. Note that while the Embedded Erase operation is in progress, the system can read data from the non-erasing bank. The system can determine the status of the erase operation by reading DQ7 or DQ6/DQ2 in the erasing bank. Refer to the "Write Operation Status" section on page 79 for information on these status bits.

Once the sector erase operation has begun, only the Erase Suspend command is valid. All other commands are ignored. However, note that a hardware reset immediately terminates the erase operation. If that occurs, the sector erase command sequence should be reinitiated once that bank has returned to reading array data, to ensure data integrity.

The host system may also initiate the sector erase command sequence while the device is in the unlock bypass mode. The command sequence is four cycles in length instead of six cycles.

Figure 5, "Erase Operation," on page 72 illustrates the algorithm for the erase operation. Refer to the Erase/Program Operations table in the Figure, "AC Characteristics," on page 98 for parameters and timing diagrams.

Erase Suspend/Erase Resume Commands

The Erase Suspend command, B0h, allows the system to interrupt a sector erase operation and then read data from, or program data to, any sector not selected for erasure. The bank address is required when writing this command. This command is valid only during the sector erase operation, including the minimum 50 μ s time-out period during the sector erase command sequence. The Erase Suspend command is ignored if written during the chip erase operation or Embedded Program algorithm.

When the Erase Suspend command is written during the sector erase operation, the device requires a maximum of 35 μ s to suspend the erase operation. However, when the Erase Suspend command is written during the sector erase time-out, the device immediately terminates the time-out period and suspends the erase operation.

After the erase operation has been suspended, the bank enters the erase-suspend-read mode. The system can read data from or program data to any sector not selected for erasure. (The device "erase suspends" all sectors selected for erasure.) Reading at any address within erase-suspended sectors produces status information on DQ7–DQ0. The system can use DQ7, or DQ6 and DQ2 together, to determine if a sector is actively erasing or is erase-suspended. Refer to the Figure, "Write Operation Status," on page 79 for information on these status bits.

After an erase-suspended program operation is complete, the bank returns to the erase-suspend-read mode. The system can determine the status of the program operation using the DQ7 or DQ6 status bits, just as in the standard program operation. Refer to the "Write Operation Status" section on page 79 for more information.

In the erase-suspend-read mode, the system can also issue the autoselect command sequence. Refer to the "Autoselect Mode" section on page 29 and "Autoselect Command Sequence" section on page 67 for details.

To resume the sector erase operation, the system must write the Erase Resume command. The bank address of the erase-suspended bank is required when writing this command. Further writes of the Resume command are ignored. Another Erase Suspend command can be written after the chip has resumed erasing.

Notes:

1. See Table 18 for erase command sequence.
2. See the section on DQ3 for information on the sector erase timer.

Figure 5. Erase Operation

Password Program Command

The Password Program Command permits programming the password that is used as part of the hardware protection scheme. The actual password is 64-bits long. 4 Password Program commands are required to program the password. The user must enter the unlock cycle, password program command (38h) and the program address/data for each portion of the password when programming. There are no provisions for entering the 2-cycle unlock cycle, the password program command, and all the password data. There is no special addressing order required for programming the password. Also, when the password is undergoing programming, Simultaneous Operation is disabled. Read operations to any memory location will return the programming status except DQ7. Once programming is complete, the user must issue a Secured Silicon Exit command to return the device to normal operation. Once the Password is written and verified, the Password Mode Locking Bit must be set in order to prevent verification. The Password Program Command is only capable of programming "0"s. Programming a "1" after a cell is programmed as a "0" results in a time-out by the Embedded Program Algorithm™ with the cell remaining as a "0". The password is all F's when shipped from the factory. All 64-bit password combinations are valid as a password.

Password Verify Command

The Password Verify Command is used to verify the Password. The Password is verifiable only when the Password Mode Locking Bit is not programmed. If the Password Mode Locking Bit is programmed and the user attempts to verify the Password, the device will always drive all F's onto the DQ data bus.

Also, the device will not operate in Simultaneous Operation when the Password Verify command is executed. Only the password is returned regardless of the bank address. The lower two address bits (A1–A0) are valid during the Password Verify. Writing the Secured Silicon Exit command returns the device back to normal operation.

Password Protection Mode Locking Bit Program Command

The Password Protection Mode Locking Bit Program Command programs the Password Protection Mode Locking Bit, which prevents further verifies or updates to the password. Once programmed, the Password Protection Mode Locking Bit cannot be erased and the Persistent Protection Mode Locking Bit program circuitry is disabled, thereby forcing the device to remain in the Password Protection Mode. After issuing "PL/68h" at the fourth bus cycle, the device requires a time out period of approximately 150 μ s for programming the Password Protection Mode Locking Bit. Then by writing "PL/48h" at the fifth bus cycle, the device outputs verify data at DQ0. If DQ0 = 1, then the Password Protection Mode Locking Bit is programmed. If not, the system must repeat this program sequence from the fourth cycle of "PL/68h". Exiting the Password Protection Mode Locking Bit Program command is accomplished by writing the Secured Silicon Sector command.

Persistent Sector Protection Mode Locking Bit Program Command

The Persistent Sector Protection Mode Locking Bit Program Command programs the Persistent Sector Protection Mode Locking Bit, which prevents the Password Mode Locking Bit from ever being programmed. By disabling the program circuitry of the Password Mode Locking Bit, the device is forced to remain in the Persistent Sector Protection mode of operation, once this bit is set. After issuing "SMPL/68h" at the fourth bus cycle, the device requires a time out period of approximately 150 μ s for programming the Persistent Protection Mode Locking Bit. Then by writing "SMPL/48h" at the fifth bus cycle, the device outputs verify data at DQ0. If DQ0 = 1, then the Persistent Protection Mode Locking Bit is programmed. If not, the system must repeat this program sequence from the fourth cycle of "PL/68h". Exiting the Persistent Protection Mode Locking Bit Program command is accomplished by writing the Secured Silicon Sector Exit command.

Secured Silicon Sector Protection Bit Program Command

To protect the Secured Silicon Sector, write the Secured Silicon Sector Protect command sequence while in the Secured Silicon Sector mode. After issuing "OPBP/48h" at the fourth bus cycle, the device requires a time out period of approximately 150 μ s to protect the Secured Silicon Sector. Then, by writing "OPBP/48" at the fifth bus cycle, the device outputs verify data at DQ0. If DQ0 = 1, then the Secured Silicon Sector is protected. If not, then the system must repeat this program sequence from the fourth cycle of "OPBP/48h".

PPB Lock Bit Set Command

The PPB Lock Bit Set command is used to set the PPB Lock bit if it is cleared either at reset or if the Password Unlock command was successfully executed. There is no PPB Lock Bit Clear command. Once the PPB Lock Bit is set, it cannot be cleared unless the device is taken through a power-on clear or the Password Unlock command is executed. Upon setting the PPB Lock Bit, the PPBs are latched into the DPBs. If the Password Mode Locking Bit is set, the PPB Lock Bit status is reflected as set, even after a power-on reset cycle. Exiting the PPB Lock Bit Set command is accomplished by writing the Secured Silicon Exit command, only while in the Persistent Sector Protection Mode.

DPB Write/Erase/Status Command

The DPB Write command is used to set or clear a DPB for a given sector. The high order address bits (Amax–A11) are issued at the same time as the code 01h or 00h on DQ7–DQ0. All other DQ data bus pins are ignored during the data write cycle. The DPBs are modifiable at any time, regardless of the state of the PPB or PPB Lock Bit. If the PPB is set, the sector is protected regardless of the value of the DPB. If the PPB is cleared, setting the DPB to a 1 protects the sector from programs or erases. Since this is a volatile bit, removing power or resetting the device will clear the DPBs. The programming of the DPB for a given sector can be verified by writing a DPB Status command to the device. Exiting the DPB Write/Erase command is accomplished by writing the Read/Reset command. Exiting the DPB Status command is accomplished by writing the Secured Silicon Sector Exit command

Password Unlock Command

The Password Unlock command is used to clear the PPB Lock Bit so that the PPBs can be unlocked for modification, thereby allowing the PPBs to become accessible for modification. The exact password must be entered in order for the unlocking function to occur. This command cannot be issued any faster than 2 μ s at a time to prevent a hacker from running through the all 64-bit combinations in an attempt to correctly match a password. If the command is issued before the 2 μ s execution window for each portion of the unlock, the command will be ignored.

The Password Unlock function is accomplished by writing Password Unlock command and data to the device to perform the clearing of the PPB Lock Bit. The password is 64 bits long, so the user must write the Password Unlock command 4 times. A1 and A0 are used for matching. Writing the Password Unlock command is not address order specific. The lower address A1–A0= 00, the next Password Unlock command is to A1–A0= 01, then to A1–A0= 10, and finally to A1–A0= 11.

Once the Password Unlock command is entered for all four words, the RDY pin goes LOW indicating that the device is busy. Also, reading the Bank D results in the DQ6 pin toggling, indicating that the Password Unlock function is in progress. Reading the other bank returns actual array data. Approximately 1 μ s is required for each portion of the unlock. Once the first portion of the password unlock completes (RDY is not driven and DQ6 does not toggle when read), the Password Unlock command is issued again, only this time with the next part of the password. Four Password Unlock commands are required to successfully clear the PPB Lock Bit. As with the first Password Unlock command, the RDY signal goes LOW and reading the device results in the DQ6 pin toggling on successive read operations until complete. It is the responsibility of the micro-

processor to keep track of the number of Password Unlock commands, the order, and when to read the PPB Lock bit to confirm successful password unlock. In order to re lock the device into the Password Mode, the PPB Lock Bit Set command can be re-issued.

PPB Program Command

The PPB Program command is used to program, or set, a given PPB. Each PPB is individually programmed (but is bulk erased with the other PPBs). The specific sector address (Amax–A12) are written at the same time as the program command 60h with A6 = 0. If the PPB Lock Bit is set and the corresponding PPB is set for the sector, the PPB Program command will not execute and the command will time-out without programming the PPB.

After programming a PPB, two additional cycles are needed to determine whether the PPB has been programmed with margin. After 4th cycle, the device requires approximately 150 μ s time out period for programming the PPB. And then after 5th cycle, the device outputs verify data at DQ0.

The PPB Program command does not follow the Embedded Program algorithm. Writing the Secured Silicon Sector Exit command returns the device back to normal operation.

All PPB Erase Command

The All PPB Erase command is used to erase all PPBs in bulk. There is no means for individually erasing a specific PPB. Unlike the PPB program, no specific sector address is required. However, when the PPB erase command is written (60h) and A6 = 1, all Sector PPBs are erased in parallel. If the PPB Lock Bit is set the ALL PPB Erase command will not execute and the command will time-out without erasing the PPBs.

After erasing the PPBs, two additional cycles are needed to determine whether the PPB has been erased with margin. After 4th cycle, the device requires approximately 1.5 ms time out period for erasing the PPB. And then after 5th cycle, the device outputs verify data at DQ0.

It is the responsibility of the user to preprogram all PPBs prior to issuing the All PPB Erase command. If the user attempts to erase a cleared PPB, over-erasure may occur making it difficult to program the PPB at a later time. Also note that the total number of PPB program/erase cycles is limited to 100 cycles. Cycling the PPBs beyond 100 cycles is not guaranteed. Writing the Secured Silicon Sector Exit command returns the device back to normal operation.

PPB Status Command

The programming of the PPB for a given sector can be verified by writing a PPB status verify command to the device.

PPB Lock Bit Status Command

The programming of the PPB Lock Bit for a given sector can be verified by writing a PPB Lock Bit status verify command to the device.

Command Definitions

Table 18. Command Definitions

| Command Sequence (Note 1) | | Cycles | Bus Cycles (Notes 1–6) | | | | | | | | | | | | | |

Legend:

X = Don't care

RA = Address of the memory location to be read.

RD = Data read from location RA during read operation.

PA = Address of the memory location to be programmed. Addresses latch on the rising edge of the AVD# pulse or active edge of CLK which ever comes first.

PD = Data to be programmed at location PA. Data latches on the rising edge of WE# or CE# pulse, whichever happens first.

SA = Address of the sector to be verified (in autoselect mode) or erased. Address bits Amax-A12 uniquely select any sector.

BA = Address of the bank (WS128J: A22, A21, A20, WS064J: A21, A20, A19) that is being switched to autoselect mode, is in bypass mode, or is being erased.

SLA = Address of the sector to be locked. Set sector address (SA) and either A6 = 1 for unlocked or A6 = 0 for locked.

CR = Configuration Register address bits A19-A12.

OW = Address (A7-A0) is (00011010).

PD3-PD0 = Password Data. PD3-PD0 present four 16 bit combinations that represent the 64-bit Password

PWA = Password Address. Address bits A1 and A0 are used to select each 16-bit portion of the 64-bit entity.

PWD = Password Data.

PL = Address (A7-A0) is (00001010)

RD(0) = DQ0 protection indicator bit. If protected, DQ0 = 1, if unprotected, DQ0 = 0.

RD(1) = DQ1 protection indicator bit. If protected, DQ1 = 1, if unprotected, DQ1 = 0.

SL = Address (A7-A0) is (00010010)

WD = Write Data. See "Configuration Register" definition for specific write data

WP = Address (A7-A0) is (00000010)

Notes:

1. See Table 1 for description of bus operations.
2. All values are in hexadecimal.
3. Except for the following, all bus cycles are write cycle: read cycle, fourth through sixth cycles of the Autoselect commands, fourth cycle of the configuration register verify and password verify commands, and any cycle reading at RD(0) and RD(1).
4. Data bits DQ15-DQ8 are don't care in command sequences, except for RD, PD, WD, PWD, and PD3-PD0.

5. Unless otherwise noted, address bits Amax–A12 are don't cares.
6. Writing incorrect address and data values or writing them in the improper sequence may place the device in an unknown state. The system must write the reset command to return the device to reading array data.
7. No unlock or command cycles required when bank is reading array data.
8. The Reset command is required to return to reading array data (or to the erase-suspend-read mode if previously in Erase Suspend) when a bank is in the autoselect mode, or if DQ5 goes high (while the bank is providing status information) or performing sector lock/unlock.
9. The fourth cycle of the autoselect command sequence is a read cycle. The system must provide the bank address. See the Autoselect Command Sequence section for more information.
10. (BA)X0Fh = 2200h (WS128J), (BA)X0Eh = 2218h (WS128J), (BA)X0Fh = 221Eh (WS064J), (BA)X0Eh = 2201h (WS064J)
11. The data is 0000h for an unlocked sector and 0001h for a locked sector
12. DQ15 - DQ8 = 0, DQ7 - Factory Lock Bit (1 = Locked, 0 = Not Locked), DQ6 -Customer Lock Bit (1 = Locked, 0 = Not Locked), DQ5 = Handshake Bit (1 = Reserved, 0 = Standard Handshake)8, DQ4 & DQ3 - Boot Code (00= Dual Boot Sector, 01= Top Boot Sector, 10= Bottom Boot Sector, 11=No Boot Sector), DQ2 - DQ0 = 001
13. The Unlock Bypass command sequence is required prior to this command sequence.
14. The Unlock Bypass Reset command is required to return to reading array data.
15. The system may read and program in non-erasing sectors, or enter the autoselect mode, when in the Erase Suspend mode. The Erase Suspend command is valid only during a sector erase operation, and requires the bank address.
16. The Erase Resume command is valid only during the Erase Suspend mode, and requires the bank address.
17. See "Set Configuration Register Command Sequence" for details.
18. Command is valid when device is ready to read array data or when device is in autoselect mode.
19. The Reset command returns the device to reading the array.
20. Regardless of CLK and AVD# interaction or Control Register bit 15 setting, command mode verifies are always asynchronous read operations.
21. ACC must be at V_{HH} during the entire operation of this command
22. The fourth cycle programs the addressed locking bit. The fifth and sixth cycles are used to validate whether the bit has been fully programmed. If DQ0 (in the sixth cycle) reads 0, the program command must be issued and verified again.
23. The fourth cycle erases all PPBs. The fifth and sixth cycles are used to validate whether the bits have been fully erased. If DQ0 (in the sixth cycle) reads 1, the erase command must be issued and verified again.
24. The entire four bus-cycle sequence must be entered for each portion of the password.
25. Before issuing the erase command, all PPBs should be programmed in order to prevent over-erasure of PPBs.
26. In the fourth cycle, 01h indicates PPB set; 00h indicates PPB not set.

Write Operation Status

The device provides several bits to determine the status of a program or erase operation: DQ2, DQ3, DQ5, DQ6, and DQ7. Table 20, "Write Operation Status," on page 85 and the following subsections describe the function of these bits. DQ7 and DQ6 each offers a method for determining whether a program or erase operation is complete or in progress.

DQ7: Data# Polling

The Data# Polling bit, DQ7, indicates to the host system whether an Embedded Program or Erase algorithm is in progress or completed, or whether a bank is in Erase Suspend. Data# Polling is valid after the rising edge of the final WE# pulse in the command sequence.

During the Embedded Program algorithm, the device outputs on DQ7 the complement of the datum programmed to DQ7. This DQ7 status also applies to programming during Erase Suspend. When the Embedded Program algorithm is complete, the device outputs the datum programmed to DQ7. The system must provide the program address to read valid status information on DQ7. If a program address falls within a protected sector, Data# Polling on DQ7 is active for approximately 1 μ s, then that bank returns to the read mode.

During the Embedded Erase algorithm, Data# Polling produces a "0" on DQ7. When the Embedded Erase algorithm is complete, or if the bank enters the Erase Suspend mode, Data# Polling produces a "1" on DQ7. The system must provide an address within any of the sectors selected for erasure to read valid status information on DQ7.

After an erase command sequence is written, if all sectors selected for erasing are protected, Data# Polling on DQ7 is active for approximately 100 μ s, then the bank returns to the read mode. If not all selected sectors are protected, the Embedded Erase algorithm erases the unprotected sectors, and ignores the selected sectors that are protected. However, if the system reads DQ7 at an address within a protected sector, the status may not be valid.

Just prior to the completion of an Embedded Program or Erase operation, DQ7 may change asynchronously with DQ6–DQ0 while Output Enable (OE#) is asserted low. That is, the device may change from providing status information to valid data on DQ7. Depending on when the system samples the DQ7 output, it may read the status or valid data. Even if the device has completed the program or erase operation and DQ7 has valid data, the data outputs on DQ6–DQ0 may be still invalid. Valid data on DQ7–DQ0 will appear on successive read cycles.

Table 20, "Write Operation Status," on page 85 shows the outputs for Data# Polling on DQ7. Figure 6, "Data# Polling Algorithm," on page 80 shows the Data# Polling algorithm. Figure 28, "Data# Polling Timings (During Embedded Algorithm)," on page 105 in the AC Characteristics section shows the Data# Polling timing diagram.

Notes:

1. VA = Valid address for programming. During a sector erase operation, a valid address is any sector address within the sector being erased. During chip erase, a valid address is any non-protected sector address.
2. DQ7 should be rechecked even if DQ5 = "1" because DQ7 may change simultaneously with DQ5.

Figure 6. Data# Polling Algorithm

RDY: Ready

The RDY is a dedicated output that, when the device is configured in the Synchronous mode, indicates (when at logic low) the system should wait 1 clock cycle before expecting the next word of data. The RDY pin is only controlled by CE#. Using the RDY Configuration Command Sequence, RDY can be set so that a logic low indicates the system should wait 2 clock cycles before expecting valid data.

The following conditions cause the RDY output to be low: during the initial access (in burst mode), and after the boundary that occurs every 64 words beginning with the 64th address, 3Fh.

When the device is configured in Asynchronous Mode, the RDY is an open-drain output pin which indicates whether an Embedded Algorithm is in progress or completed. The RDY status is valid after the rising edge of the final WE# pulse in the command sequence.

If the output is low (Busy), the device is actively erasing or programming. (This includes programming in the Erase Suspend mode.) If the output is in high impedance (Ready), the device is in the read mode, the standby mode, or in the erase-suspend-read mode. Table 20, "Write Operation Status," on page 85 shows the outputs for RDY.

DQ6: Toggle Bit I

Toggle Bit I on DQ6 indicates whether an Embedded Program or Erase algorithm is in progress or complete, or whether the device has entered the Erase Suspend mode. Toggle Bit I may be read at any address in the same bank, and is valid after the rising edge of the final WE# pulse in the command sequence (prior to the program or erase operation), and during the sector erase time-out.

During an Embedded Program or Erase algorithm operation, successive read cycles to any address cause DQ6 to toggle. When the operation is complete, DQ6 stops toggling.

After an erase command sequence is written, if all sectors selected for erasing are protected, DQ6 toggles for approximately 100 μ s, then returns to reading array data. If not all selected sectors are protected, the Embedded Erase algorithm erases the unprotected sectors, and ignores the selected sectors that are protected.

The system can use DQ6 and DQ2 together to determine whether a sector is actively erasing or is erase-suspended. When the device is actively erasing (that is, the Embedded Erase algorithm is in progress), DQ6 toggles. When the device enters the Erase Suspend mode, DQ6 stops toggling. However, the system must also use DQ2 to determine which sectors are erasing or erase-suspended. Alternatively, the system can use DQ7 (see the subsection on DQ7: Data# Polling).

If a program address falls within a protected sector, DQ6 toggles for approximately 1 ms after the program command sequence is written, then returns to reading array data.

DQ6 also toggles during the erase-suspend-program mode, and stops toggling once the Embedded Program algorithm is complete.

See the following for additional information: Figure 7, "Toggle Bit Algorithm," on page 82, "DQ6: Toggle Bit I" on page 81, Figure 29, "Toggle Bit Timings (During Embedded Algorithm)," on page 105 (toggle bit timing diagram), and Table 19, "DQ6 and DQ2 Indications," on page 83.

Toggle Bit I on DQ6 requires either OE# or CE# to be deasserted and reasserted to show the change in state.

Note: The system should recheck the toggle bit even if DQ5 = "1" because the toggle bit may stop toggling as DQ5 changes to "1." See the subsections on DQ6 and DQ2 for more information.

Figure 7. Toggle Bit Algorithm

DQ2: Toggle Bit II

The "Toggle Bit II" on DQ2, when used with DQ6, indicates whether a particular sector is actively erasing (that is, the Embedded Erase algorithm is in progress), or whether that sector is erase-suspended. Toggle Bit II is valid after the rising edge of the final WE# pulse in the command sequence.

DQ2 toggles when the system reads at addresses within those sectors that have been selected for erasure. But DQ2 cannot distinguish whether the sector is actively erasing or is erase-suspended. DQ6, by comparison, indicates whether the device is actively erasing, or is in Erase Suspend, but cannot distinguish which sectors are selected for erasure. Thus, both status bits are required for sector and mode information. Refer to Table 19, "DQ6 and DQ2 Indications," on page 83 to compare outputs for DQ2 and DQ6.

See the following for additional information: Figure 7, "Toggle Bit Algorithm," on page 82, "DQ6: Toggle Bit I" on page 81, Figure 29, "Toggle Bit Timings (During Embedded Algorithm)," on page 105, and Table 19, "DQ6 and DQ2 Indications," on page 83.

Table 19. DQ6 and DQ2 Indications

| If device is | and the system reads | then DQ6 | and DQ2 |
|------------------------------|---|---------------------|---|
| programming, | at any address, | toggles, | does not toggle. |
| actively erasing, | at an address within a sector selected for erasure, | toggles, | also toggles. |
| | at an address within sectors <i>not</i> selected for erasure, | toggles, | does not toggle. |
| erase suspended, | at an address within a sector selected for erasure, | does not toggle, | toggles. |
| | at an address within sectors <i>not</i> selected for erasure, | returns array data, | returns array data. The system can read from any sector not selected for erasure. |
| programming in erase suspend | at any address, | toggles, | is not applicable. |

Reading Toggle Bits DQ6/DQ2

Refer to Figure 7, "Toggle Bit Algorithm," on page 82 for the following discussion. Whenever the system initially begins reading toggle bit status, it must read DQ7–DQ0 at least twice in a row to determine whether a toggle bit is toggling. Typically, the system would note and store the value of the toggle bit after the first read. After the second read, the system would compare the new value of the toggle bit with the first. If the toggle bit is not toggling, the device has completed the program or erase operation. The system can read array data on DQ7–DQ0 on the following read cycle.

However, if after the initial two read cycles, the system determines that the toggle bit is still toggling, the system also should note whether the value of DQ5 is high (see the section on DQ5). If it is, the system should then determine again whether the toggle bit is toggling, since the toggle bit may have stopped toggling just as DQ5 went high. If the toggle bit is no longer toggling, the device has successfully completed the program or erase operation. If it is still toggling, the device did not complete the operation successfully, and the system must write the reset command to return to reading array data.

The remaining scenario is that the system initially determines that the toggle bit is toggling and DQ5 has not gone high. The system may continue to monitor the toggle bit and DQ5 through successive read cycles, determining the status as described in the previous paragraph. Alternatively, it may choose to perform other

system tasks. In this case, the system must start at the beginning of the algorithm when it returns to determine the status of the operation (Figure 7, "Toggle Bit Algorithm," on page 82).

DQ5: Exceeded Timing Limits

DQ5 indicates whether the program or erase time has exceeded a specified internal pulse count limit. Under these conditions DQ5 produces a "1," indicating that the program or erase cycle was not successfully completed.

The device may output a "1" on DQ5 if the system tries to program a "1" to a location that was previously programmed to "0." Only an erase operation can change a "0" back to a "1." Under this condition, the device halts the operation, and when the timing limit has been exceeded, DQ5 produces a "1."

Under both these conditions, the system must write the reset command to return to the read mode (or to the erase-suspend-read mode if a bank was previously in the erase-suspend-program mode).

DQ3: Sector Erase Timer

After writing a sector erase command sequence, the system may read DQ3 to determine whether or not erasure has begun. (The sector erase timer does not apply to the chip erase command.) If additional sectors are selected for erasure, the entire time-out also applies after each additional sector erase command. When the time-out period is complete, DQ3 switches from a "0" to a "1." If the time between additional sector erase commands from the system can be assumed to be less than 50 μ s, the system need not monitor DQ3. See also "Sector Erase Command Sequence" on page 70.

After the sector erase command is written, the system should read the status of DQ7 (Data# Polling) or DQ6 (Toggle Bit 1) to ensure that the device has accepted the command sequence, and then read DQ3. If DQ3 is "1," the Embedded Erase algorithm has begun; all further commands (except Erase Suspend) are ignored until the erase operation is complete. If DQ3 is "0," the device will accept additional sector erase commands. To ensure the command has been accepted, the system software should check the status of DQ3 prior to and following each subsequent sector erase command. If DQ3 is high on the second status check, the last command might not have been accepted.

Table 20 shows the status of DQ3 relative to the other status bits.

Table 20. Write Operation Status

| Status | | DQ7 (Note 2) | DQ6 | DQ5 (Note 1) | DQ3 | DQ2 (Note 2) | RDY (Note 5) | |
|--------------------|-----------------------------|----------------------------|--------|-----------------------|------|-----------------------|-----------------|----------------|
| Standard Mode | Embedded Program Algorithm | DQ7# | Toggle | 0 | N/A | No toggle (Note 6) | 0 | |
| | Embedded Erase Algorithm | 0 | Toggle | 0 | 1 | Toggle | 0 | |
| Erase Suspend Mode | Erase-Suspend-Read (Note 4) | Erase Suspended Sector | 1 | No toggle (Note 6) | 0 | N/A | Toggle | High Impedance |
| | | Non-Erase Suspended Sector | Data | Data | Data | Data | Data | High Impedance |
| | Erase-Suspend-Program | DQ7# | Toggle | 0 | N/A | N/A | 0 | |

Notes:

1. DQ5 switches to '1' when an Embedded Program or Embedded Erase operation has exceeded the maximum timing limits. Refer to the section on DQ5 for more information.
2. DQ7 and DQ2 require a valid address when reading status information. Refer to the appropriate subsection for further details.
3. When reading write operation status bits, the system must always provide the bank address where the Embedded Algorithm is in progress. The device outputs array data if the system addresses a non-busy bank.
4. The system may read either asynchronously or synchronously (burst) while in erase suspend.
5. The RDY pin acts a dedicated output to indicate the status of an embedded erase or program operation is in progress. This is available in the Asynchronous mode only.
6. When the device is set to Asynchronous mode, these status flags should be read by CE# toggle.

Absolute Maximum Ratings

| | |
|--|----------------------------|
| Storage Temperature, Plastic Packages | -65°C to +150°C |
| Ambient Temperature with Power Applied | -65°C to +125°C |
| Voltage with Respect to Ground: | |
| All Inputs and I/Os except as noted below (Note 1) | -0.5 V to $V_{IO} + 0.5$ V |
| V_{CC} (Note 1) | -0.5 V to +2.5 V |
| V_{IO} | -0.5 V to +2.5 V |
| A9, RESET#, ACC (Note 1) | -0.5 V to +12.5 V |
| Output Short Circuit Current (Note 3) | 100 mA |

Notes:

1. Minimum DC voltage on input or I/Os is -0.5 V. During voltage transitions, inputs or I/Os may undershoot V_{SS} to -2.0 V for periods of up to 20 ns. See Figure 8. Maximum DC voltage on input or I/Os is $V_{CC} + 0.5$ V. During voltage transitions outputs may overshoot to $V_{CC} + 2.0$ V for periods up to 20 ns. See Figure 9.
2. No more than one output may be shorted to ground at a time. Duration of the short circuit should not be greater than one second.
3. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational sections of this data sheet is not implied. Exposure of the device to absolute maximum rating conditions for extended periods may affect device reliability.

Figure 8. Maximum Negative Overshoot Waveform

Figure 9. Maximum Positive Overshoot Waveform

Operating Ranges

Commercial (C) Devices

Ambient Temperature (T_A) 0°C to +70°C

Industrial (I) Devices

Ambient Temperature (T_A)..... -40°C to +85°C

Supply Voltages

V_{CC} Supply Voltages +1.65 V to +1.95 V

V_{IO} Supply Voltages: +1.65 V to +1.95 V

$V_{CC} \geq V_{IO} - 100\text{mV}$

Operating ranges define those limits between which the functionality of the device is guaranteed.

DC Characteristics

CMOS Compatible

| Parameter | Description | Test Conditions Notes: 1 & 2 | Min | Typ | Max | Unit |
|-----------|---|--|----------------|-----|----------------|---------|
| I_{LI} | Input Load Current | $V_{IN} = V_{SS}$ to V_{CC} , $V_{CC} = V_{CCmax}$ | | | ± 1 | μA |

| V_{OH} | Output High Voltage | $I_{OH} = -100 \mu A$, $V_{CC} = V_{CC min} = V_{IO}$ | $V_{IO} - 0.1$ | | | V |
| V_{ID} | Voltage for Autoselect and Temporary Sector Unprotect | $V_{CC} = 1.8 V$ | 11.5 | | 12.5 | V |
| V_{HH} | Voltage for Accelerated Program | | 11.5 | | 12.5 | V |
| V_{LKO} | Low V_{CC} Lock-out Voltage | | 1.0 | | 1.4 | V |

Notes:

1. Maximum I_{CC} specifications are tested with $V_{CC} = V_{CCmax}$.
2. $V_{CC} = V_{IO}$
3. The I_{CC} current listed is typically less than 2 mA/MHz, with OE# at V_{IH} .
4. I_{CC} active while Embedded Erase or Embedded Program is in progress.
5. Device enters automatic sleep mode when addresses are stable for $t_{ACC} + 60 ns$. Typical sleep mode current is equal to I_{CC3} .
6. Total current during accelerated programming is the sum of V_{ACC} and V_{CC} currents.

Test Conditions

Figure 10. Test Setup

Table 21. Test Specifications

| Test Condition | All Speed Options | Unit |
|---|-------------------|------|
| Output Load Capacitance, C_L (including jig capacitance) | 30 | pF |
| Input Rise and Fall Times | 2.5 - 3 | ns |
| Input Pulse Levels | 0.0- V_{IO} | V |
| Input timing measurement reference levels | $V_{IO}/2$ | V |
| Output timing measurement reference levels | $V_{IO}/2$ | V |

Key to Switching Waveforms

| Waveform | Inputs | Outputs |
|---|----------------------------------|--|
|  | Steady | |

Note: Addresses are latched on the first of either the active edge of CLK or the rising edge of AVD#.

AC Characteristics

Notes:

1. Figure shows total number of wait states set to seven cycles. The total number of wait states can be programmed from two cycles to seven cycles.
2. If any burst address occurs at a 64-word boundary, two additional clock cycle are inserted, and is indicated by RDY.
3. The device is in synchronous mode.

Figure 14. CLK Synchronous Burst Mode Read (rising active CLK)

Notes:

1. Figure shows total number of wait states set to four cycles. The total number of wait states can be programmed from two cycles to seven cycles. Clock is set for active falling edge.
2. If any burst address occurs at a 64-word boundary, two additional clock cycle are inserted, and is indicated by RDY.
3. The device is in synchronous mode.

Figure 15. CLK Synchronous Burst Mode Read (Falling Active Clock)

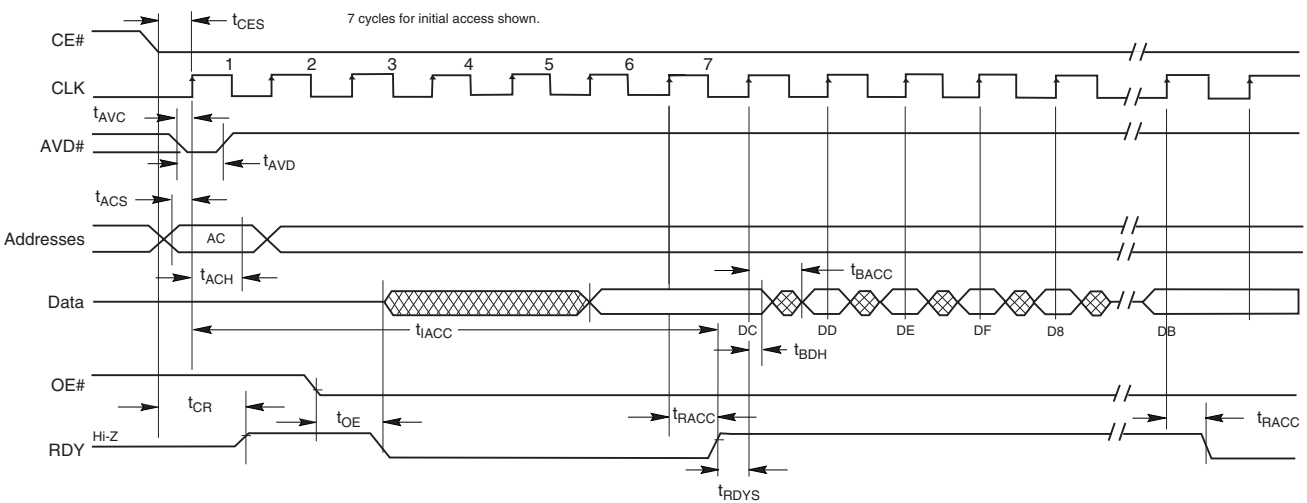

AC Characteristics

Notes:

1. Figure shows total number of wait states set to seven cycles. The total number of wait states can be programmed from two cycles to seven cycles. Clock is set for active rising edge.
2. If any burst address occurs at a 64-word boundary, two additional clock cycle are inserted, and is indicated by RDY.
3. The device is in synchronous mode.

Figure 16. Synchronous Burst Mode Read

Notes:

1. Figure shows total number of wait states set to seven cycles. The total number of wait states can be programmed from two cycles to seven cycles. Clock is set for active rising edge.
2. If any burst address occurs at a 64-word boundary, two additional clock cycle are inserted, and is indicated by RDY.
3. The device is in synchronous mode with wrap around.
4. D0-D7 in data waveform indicates the order the data within a given 8-word address range, from lowest to highest. Starting address in figure is the 4th address in range (AC)

Figure 17. 8-word Linear Burst with Wrap Around

AC Characteristics

Notes:

1. Figure assumes 6 wait states for initial access and synchronous read.
2. The Set Configuration Register command sequence has been written with A18=0; device will output RDY one cycle before valid data.

Figure 18. Linear Burst with RDY Set One Cycle Before Data

AC Characteristics

Asynchronous Mode Read @ $V_{IO} = 1.8\text{ V}$

| Parameter | | Description | | 66 MHz | 80 MHz | Unit | |
|-----------|-------------|---|--------------------------|-----------|-----------|------|----|
| JEDEC | Standard | | | | | | |
| | t_{CE} | Access Time from CE# Low | Max | 55 | 45 | ns | |
| | t_{ACC} | Asynchronous Access Time (Note 1) | Max | 55 | 45 | ns | |
| | t_{AVDP} | AVD# Low Time | Min | 10 | | ns | |
| | t_{AAVDS} | Address Setup Time to Rising Edge of AVD | Min | 4 | | ns | |
| | t_{AAVDH} | Address Hold Time from Rising Edge of AVD | Min | 5.5 | | ns | |
| | t_{OE} | Output Enable to Output Valid | Max | 11.2 | 9.1 | ns | |
| | t_{OEH} | Output Enable Hold Time | Read | Min | 0 | | ns |
| | | | Toggle and Data# Polling | Min | 8 | | ns |
| | t_{OEZ} | Output Enable to High Z (Note 2) | Max | 8 | | ns | |
| | t_{CAS} | CE# Setup Time to AVD# | Min | 0 | | ns | |

Notes:

1. Asynchronous Access Time is from the last of either stable addresses or the falling edge of AVD#.
2. Not 100% tested.

AC Characteristics

Note: RA = Read Address, RD = Read Data.

Figure 19. Asynchronous Mode Read with Latched Addresses

Note: RA = Read Address, RD = Read Data.

| | t_{AVHC} | AVD# Hold Time to CLK | Min | 4 | | ns |
| | t_{CSW} | Clock Setup Time to WE# | Min | 5 | | ns |

Notes:

1. Not 100% tested.
2. Asynchronous mode allows both Asynchronous and Synchronous program operation. Synchronous mode allows both Asynchronous and Synchronous program operation.
3. In asynchronous program operation timing, addresses are latched on the falling edge of WE# or rising edge of AVD#. In synchronous program operation timing, addresses are latched on the first of either the rising edge of AVD# or the active edge of CLK.
4. See the "Erase and Programming Performance" section for more information.
5. Does not include the preprogramming time.

AC Characteristics

Notes:

1. PA = Program Address, PD = Program Data, VA = Valid Address for reading status bits.
2. "In progress" and "complete" refer to status of program operation.
3. A22-A12 are don't care during command sequence unlock cycles.
4. CLK can be either V_{IL} or V_{IH}.
5. The Asynchronous programming operation is independent of the Set Device Read Mode bit in the Configuration Register.

Figure 22. Asynchronous Program Operation Timings: AVD# Latched Addresses

AC Characteristics

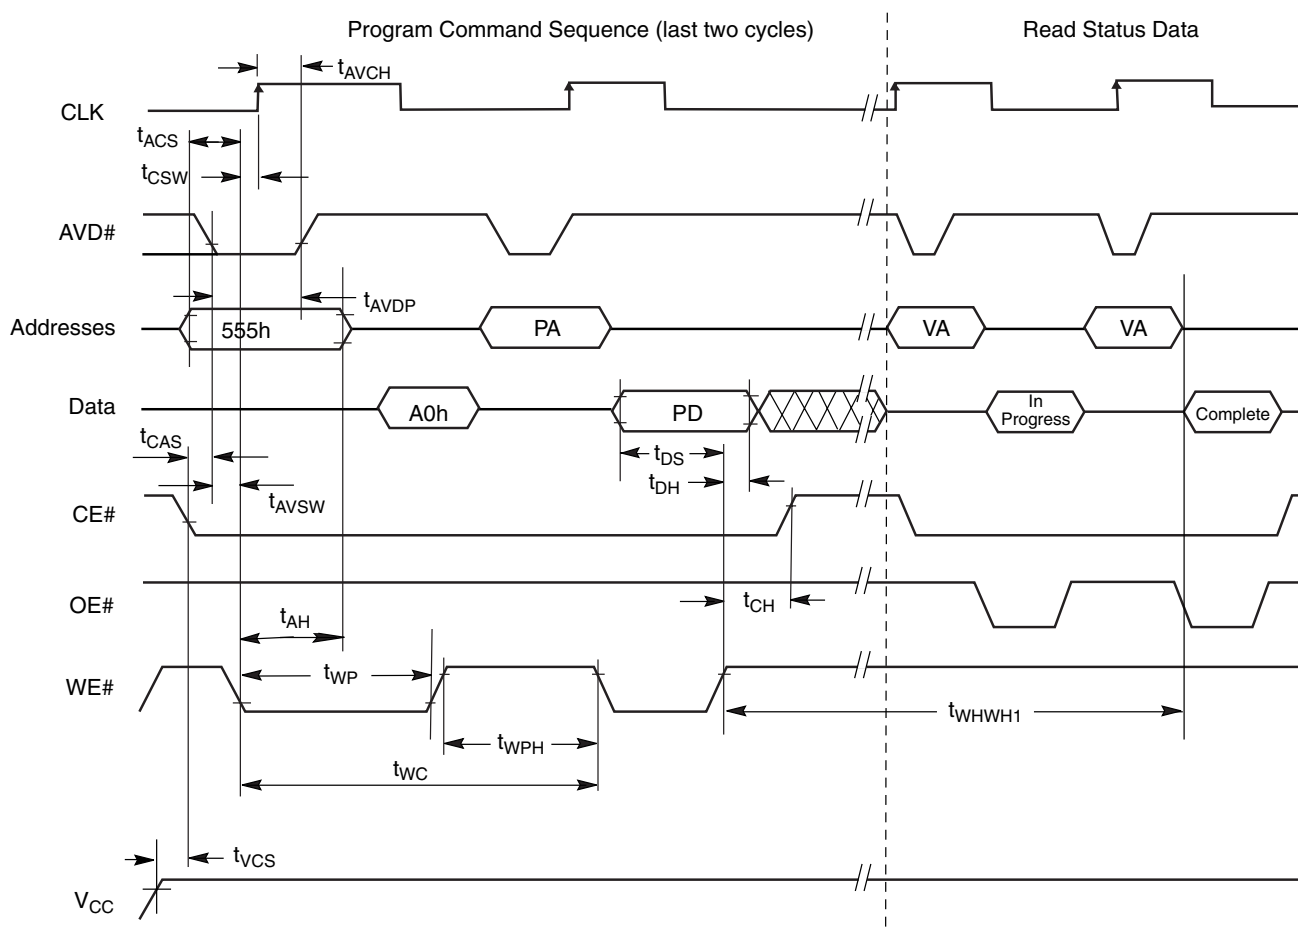

Notes:

1. PA = Program Address, PD = Program Data, VA = Valid Address for reading status bits.
2. "In progress" and "complete" refer to status of program operation.
3. A22-A12 are don't care during command sequence unlock cycles.
4. CLK can be either V_{IL} or V_{IH} .
5. The Asynchronous programming operation is independent of the Set Device Read Mode bit in the Configuration Register.

Figure 23. Asynchronous Program Operation Timings: WE# Latched Addresses

AC Characteristics

Notes:

1. PA = Program Address, PD = Program Data, VA = Valid Address for reading status bits.
2. "In progress" and "complete" refer to status of program operation.
3. A22-A12 are don't care during command sequence unlock cycles.
4. Addresses are latched on the first of either the rising edge of AVD# or the active edge of CLK.
5. Either CE# or AVD# is required to go from low to high in between programming command sequences.
6. The Synchronous programming operation is dependent of the Set Device Read Mode bit in the Configuration Register. The Configuration Register must be set to the Synchronous Read Mode.

Figure 24. Synchronous Program Operation Timings: WE# Latched Addresses

AC Characteristics

Notes:

1. PA = Program Address, PD = Program Data, VA = Valid Address for reading status bits.
2. "In progress" and "complete" refer to status of program operation.
3. A22-A12 are don't care during command sequence unlock cycles.
4. Addresses are latched on the first of either the rising edge of AVD# or the active edge of CLK.
5. Either CE# or AVD# is required to go from low to high in between programming command sequences.
6. The Synchronous programming operation is dependent of the Set Device Read Mode bit in the Configuration Register. The Configuration Register must be set to the Synchronous Read Mode.

Figure 25. Synchronous Program Operation Timings: CLK Latched Addresses

AC Characteristics

Figure 26. Chip/Sector Erase Command Sequence

Notes:

1. SA is the sector address for Sector Erase.
2. Address bits A22-A12 are don't cares during unlock cycles in the command sequence.

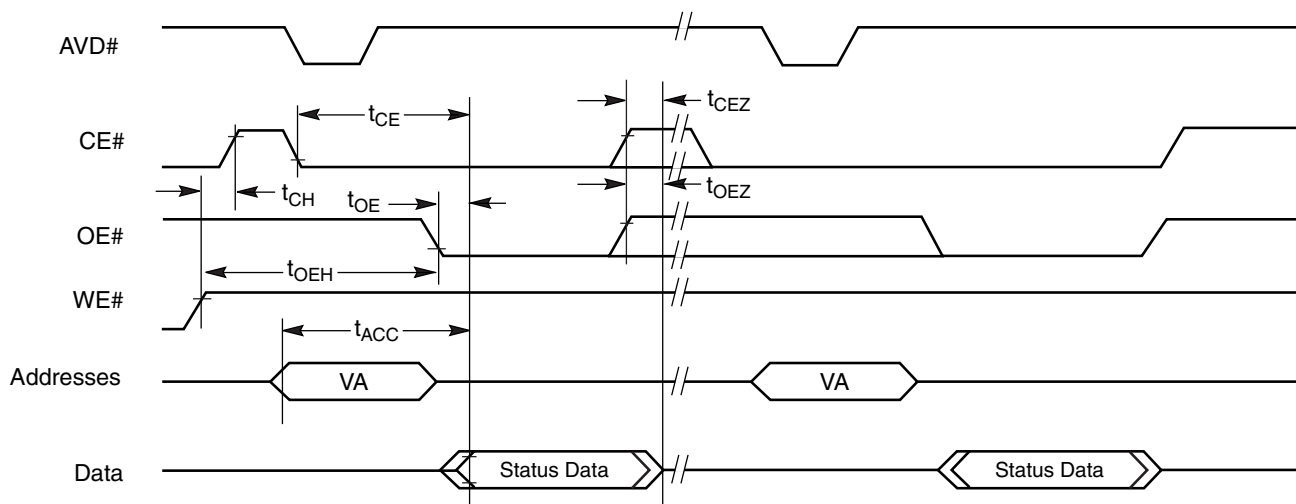

AC Characteristics

Note: Use setup and hold times from conventional program operation.

Figure 27. Accelerated Unlock Bypass Programming Timing

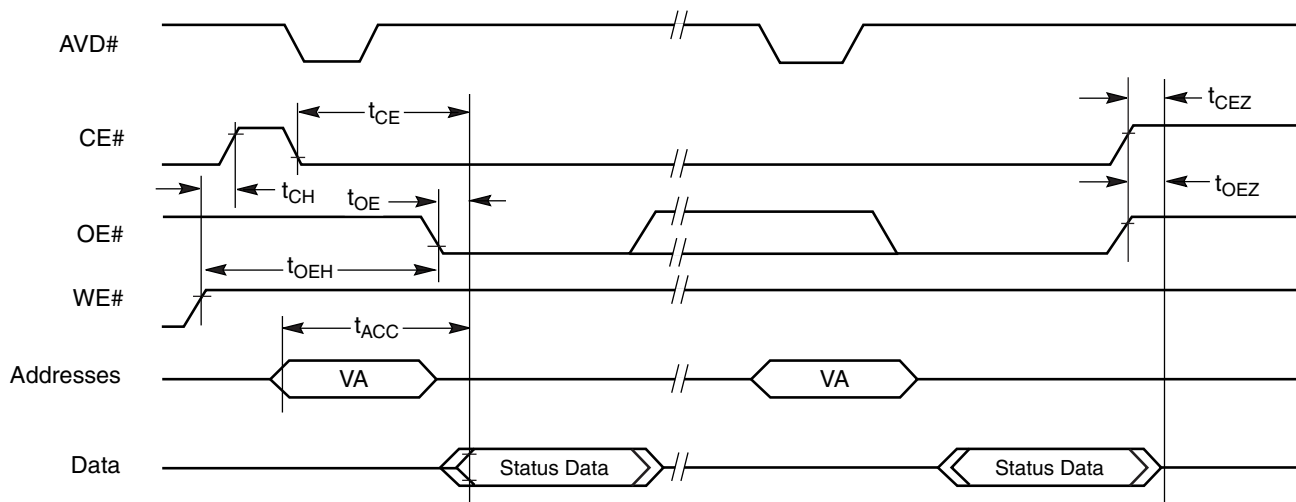

AC Characteristics

Notes:

1. Status reads in figure are shown as asynchronous.
2. VA = Valid Address. Two read cycles are required to determine status. When the Embedded Algorithm operation is complete, and Data# Polling will output true data.
3. While in Asynchronous mode, RDY will be low while the device is in embedded erase or programming mode.

Figure 28. Data# Polling Timings (During Embedded Algorithm)

Notes:

1. Status reads in figure are shown as asynchronous.
2. VA = Valid Address. Two read cycles are required to determine status. When the Embedded Algorithm operation is complete, the toggle bits will stop toggling.
3. While in Asynchronous mode, RDY will be low while the device is in embedded erase or programming mode.

Figure 29. Toggle Bit Timings (During Embedded Algorithm)

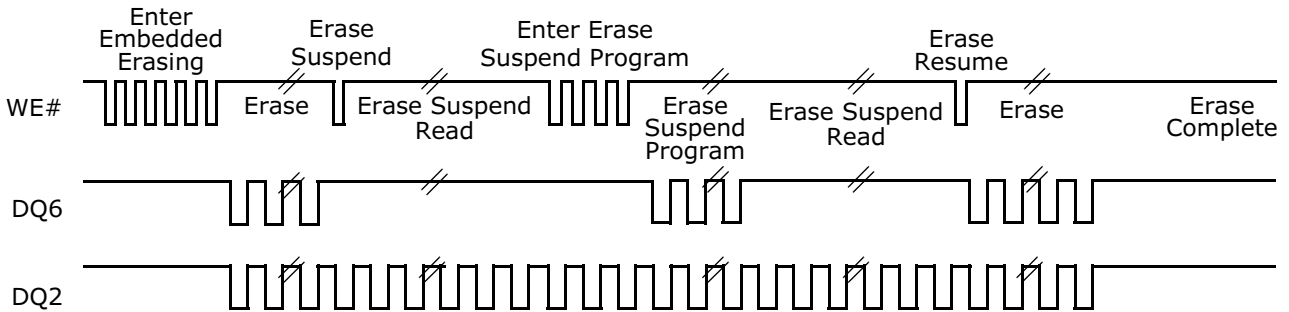

AC Characteristics

Notes:

1. The timings are similar to synchronous read timings.
2. VA = Valid Address. Two read cycles are required to determine status. When the Embedded Algorithm operation is complete, the toggle bits will stop toggling.
3. RDY is active with data (A18 = 0 in the Configuration Register). When A18 = 1 in the Configuration Register, RDY is active one clock cycle before data.

Figure 30. Synchronous Data Polling Timings/Toggle Bit Timings

Note: DQ2 toggles only when read at an address within an erase-suspended sector. The system may use OE# or CE# to toggle DQ2 and DQ6.

Figure 31. DQ2 vs. DQ6

AC Characteristics

Temporary Sector Unprotect

| Parameter | | Description | | All Speed Options | Unit |
|-----------|------------|---|-----|-------------------|---------|
| JEDEC | Std | | | | |
| | t_{VIDR} | V_{ID} Rise and Fall Time (See Note) | Min | 500 | ns |
| | t_{VHH} | V_{HH} Rise and Fall Time (See Note) | Min | 250 | ns |
| | t_{RSP} | RESET# Setup Time for Temporary Sector Unprotect | Min | 4 | μ s |
| | t_{RRB} | RESET# Hold Time from RDY High for Temporary Sector Unprotect | Min | 4 | μ s |

Note: Not 100% tested.

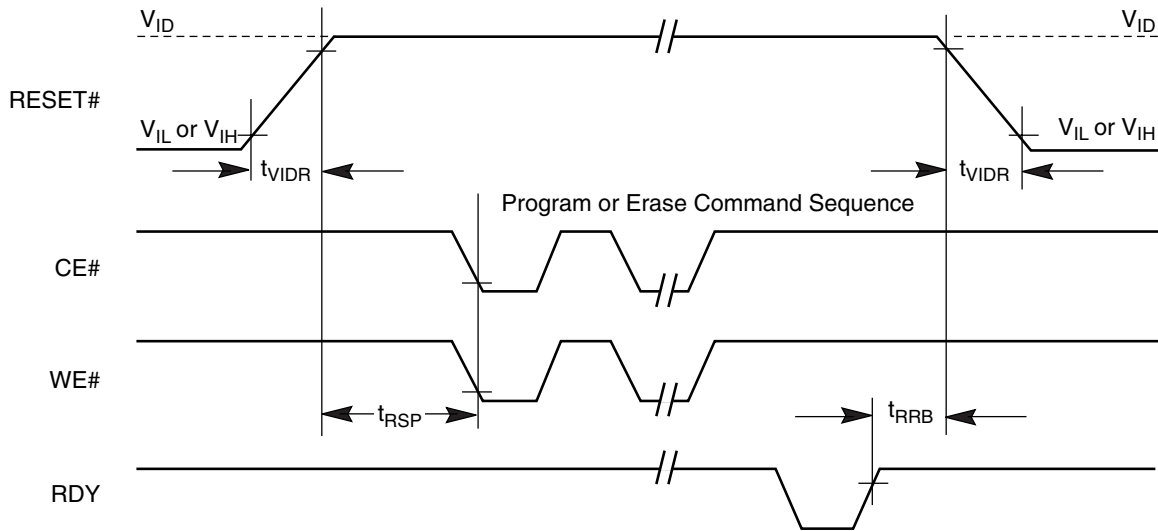

Figure 32. Temporary Sector Unprotect Timing Diagram

AC Characteristics

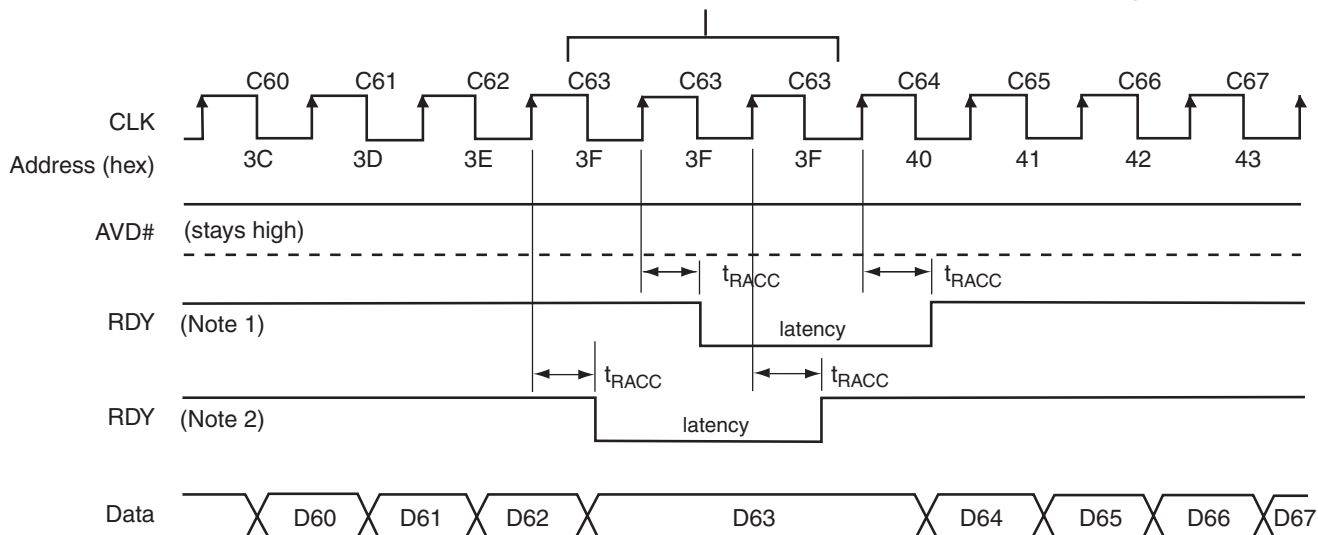

* For sector protect, $A6 = 0, A1 = 1, A0 = 0$. For sector unprotect, $A6 = 1, A1 = 1, A0 = 0$.

Figure 33. Sector/Block Protect and Unprotect Timing Diagram

AC Characteristics

Address boundary occurs every 64 words, beginning at address 00003Fh: 00007Fh, 0000BFh, etc. Address 000000h is also a boundary crossing.

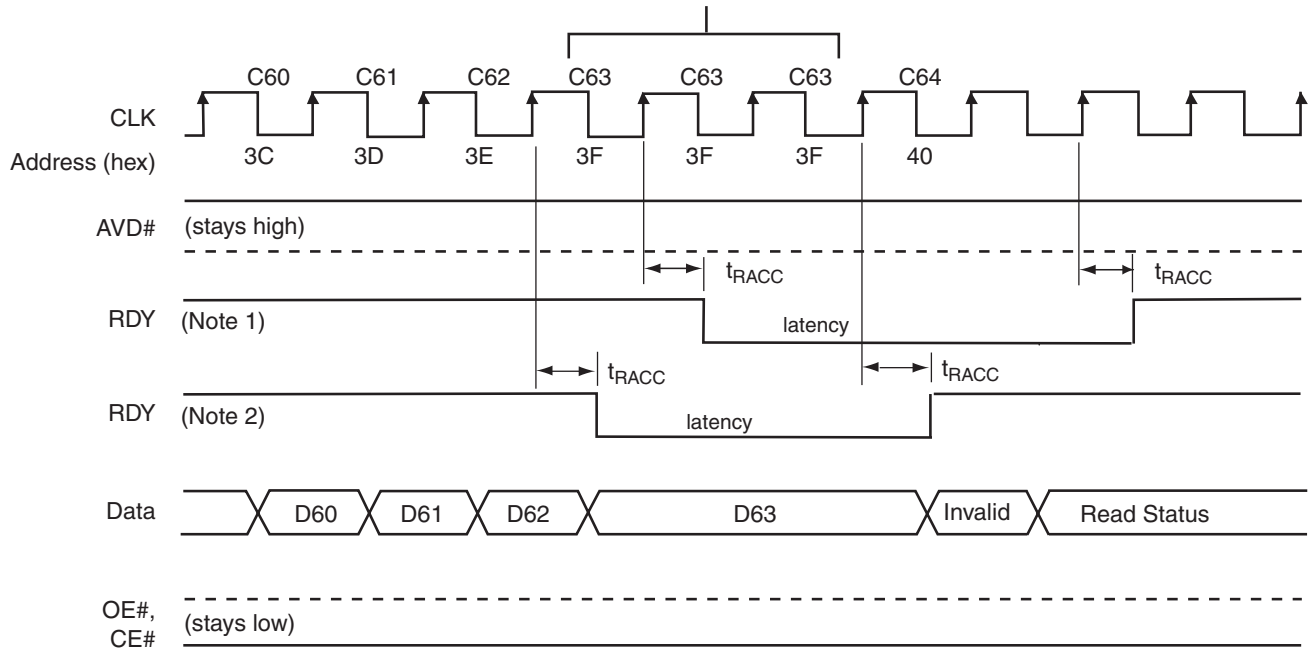

Notes:

1. RDY active with data (A18 = 0 in the Configuration Register).
2. RDY active one clock cycle before data (A18 = 1 in the Configuration Register).
3. C_{xx} indicates the clock that triggers D_{xx} on the outputs; for example, C60 triggers D60. Figure shows the device not crossing a bank in the process of performing an erase or program.
4. If the starting address latched in is either 3Eh or 3Fh (or some 64 multiple of either), there is no additional 2 cycle latency at the boundary crossing.

Figure 34. Latency with Boundary Crossing

AC Characteristics

Address boundary occurs every 64 words, beginning at address 00003Fh: 00007Fh, 0000BFh, etc. Address 000000h is also a boundary crossing.

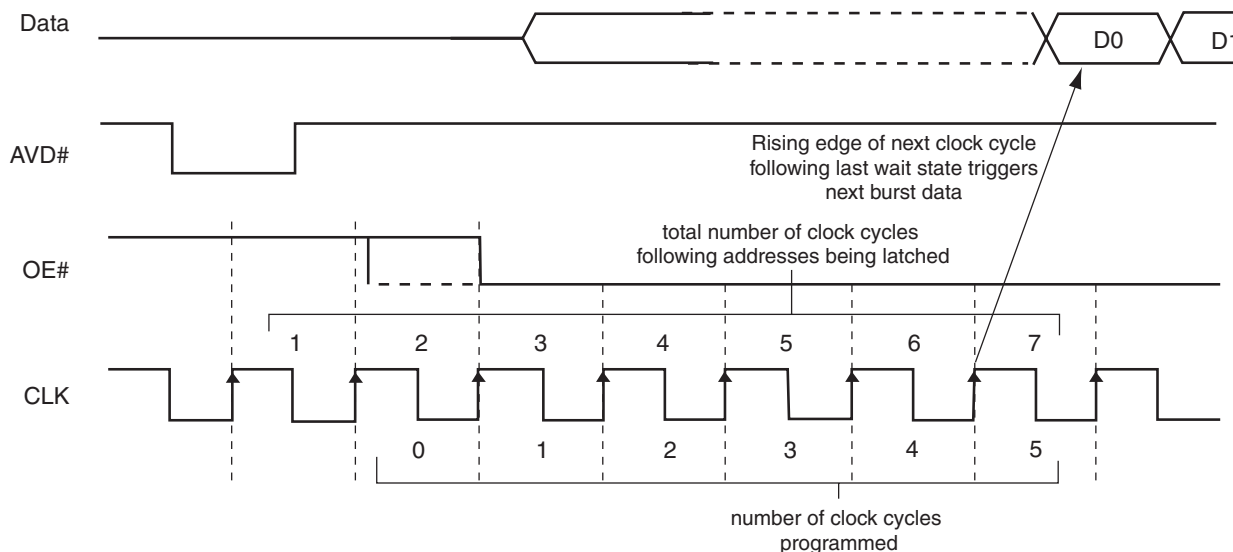

Notes:

1. RDY active with data (A18 = 0 in the Configuration Register).
2. RDY active one clock cycle before data (A18 = 1 in the Configuration Register).
3. Cxx indicates the clock that triggers Dxx on the outputs; for example, C60 triggers D60. Figure shows the device crossing a bank in the process of performing an erase or program.

Figure 35. Latency with Boundary Crossing into Program/Erase Bank

AC Characteristics

Wait State Decoding Addresses:

A14, A13, A12 = "111" ⇒ Reserved

A14, A13, A12 = "110" ⇒ Reserved

A14, A13, A12 = "101" ⇒ 5 programmed, 7 total

A14, A13, A12 = "100" ⇒ 4 programmed, 6 total

A14, A13, A12 = "011" ⇒ 3 programmed, 5 total

A14, A13, A12 = "010" ⇒ 2 programmed, 4 total

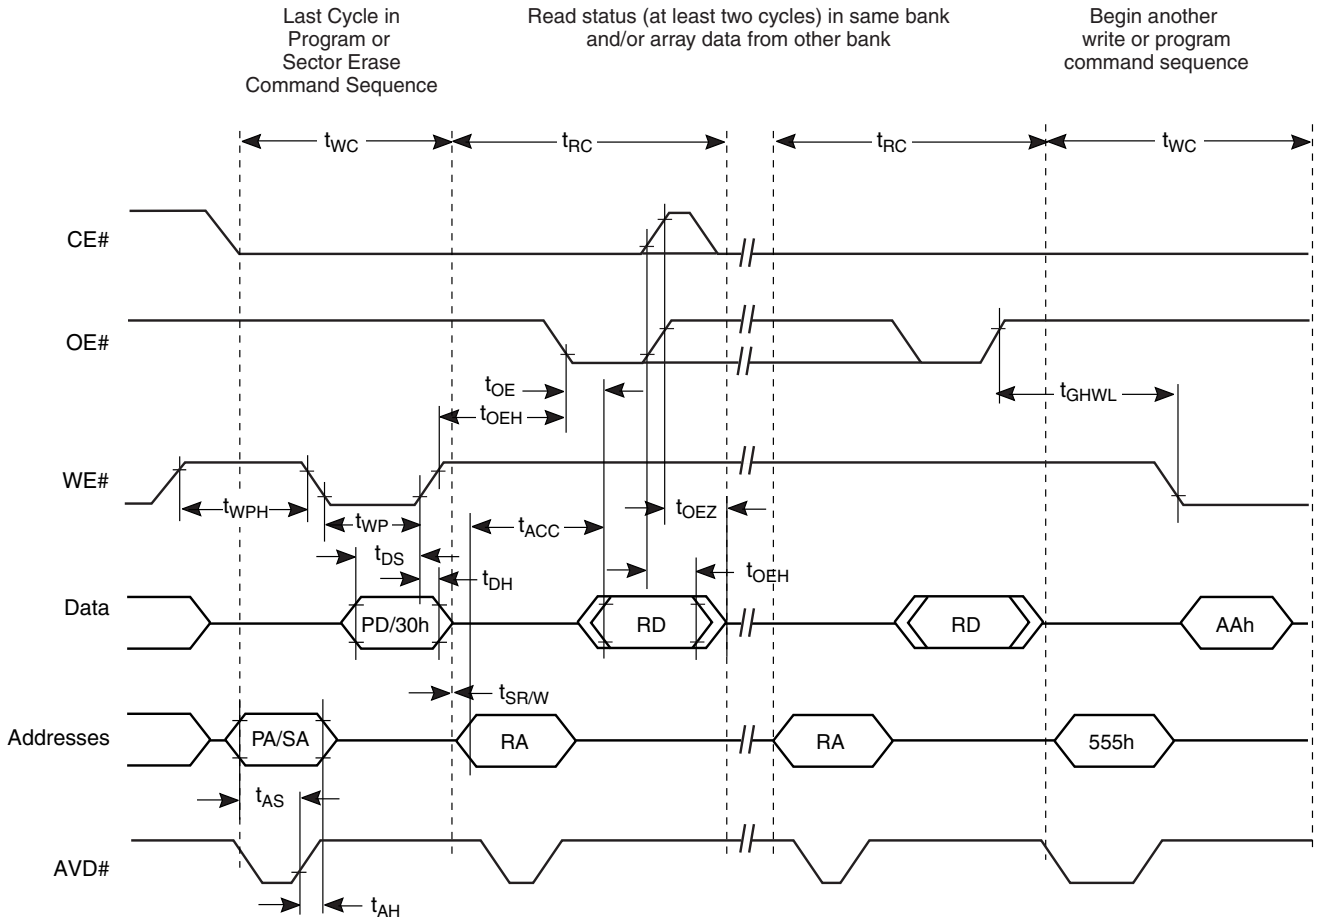

A14, A13, A12 = "001" ⇒ 1 programmed, 3 total

A14, A13, A12 = "000" ⇒ 0 programmed, 2 total

Note: Figure assumes address D0 is not at an address boundary, active clock edge is rising, and wait state is set to "101".

Figure 36. Example of Wait States Insertion

AC Characteristics

Note: Breakpoints in waveforms indicate that system may alternately read array data from the "non-busy bank" while checking the status of the program or erase operation in the "busy" bank. The system should read status twice to ensure valid information.

Figure 37. Back-to-Back Read/Write Cycle Timings

Erase and Programming Performance

| Parameter | | Typ (Note 1) | Max (Note 2) | Unit | Comments | |
|-----------------------------------|----------|--------------|--------------|------|--|---|
| Sector Erase Time | 32 Kword | <0.4 | <2 | s | Excludes 00h programming prior to erasure (Note 4) | |
| | 4 Kword | <0.2 | <2 | | | |
| Chip Erase Time | 128J | <103 | | s | | |
| | 064J | <53 | | | | |
| Word Programming Time | | <6 | <100 | μs | | Excludes system level overhead (Note 5) |
| Accelerated Word Programming Time | | <4 | <67 | μs | | |
| Chip Programming Time (Note 3) | 128J | <50.4 | | s | Excludes system level overhead (Note 5) | |
| | 064J | <25.2 | | | | |
| Accelerated Chip Programming Time | 128J | <33 | | s | | |
| | 064J | <17 | | | | |

Notes:

1. Typical program and erase times assume the following conditions: 25°C, 1.8 V V_{CC} , 100,000 cycles. Additionally, programming typicals assumes a checkerboard pattern.
2. Under worst case conditions of 90°C, $V_{CC} = 1.65$ V, 1,000,000 cycles.
3. The typical chip programming time is considerably less than the maximum chip programming time listed.
4. In the pre-programming step of the Embedded Erase algorithm, all words are programmed to 00h before erasure.
5. System-level overhead is the time required to execute the two- or four-bus-cycle sequence for the program command. See Table 18, "Command Definitions," on page 76 for further information on command definitions.
6. The device has a minimum cycling endurance of 100,000 cycles per sector.

CosmoRAM

32Mbit (2M word x 16-bit)
64Mbit (4M word x 16-bit)

PRELIMINARY

Features

- **Asynchronous SRAM Interface**
- **Fast Access Time**
 - $t_{CE} = t_{AA} = 70\text{ns}$ max
- **8 words Page Access Capability**
 - $t_{PAA} = 20\text{ns}$ max
- **Low Voltage Operating Condition**
 - $V_{DD} = +1.65\text{V}$ to $+1.95\text{V}$ (32M)
 - $+1.70\text{V}$ to $+1.95\text{V}$ (64M)
- **Wide Operating Temperature**
 - $T_A = -30^\circ\text{C}$ to $+85^\circ\text{C}$
- **Byte Control by LB# and UB#**
- **Low Power Consumption**
 - $I_{DDA1} = 30\text{mA}$ max (32M), $TBDmA$ max (64M)
 - $I_{DDS1} = 80\text{mA}$ max (32M), $TBDmA$ max (64M)
- **Various Power Down mode**
 - Sleep, 4M-bit Partial or 8M-bit Partial (32M)
 - Sleep, 8M-bit Partial or 16M-bit Partial (64M)

Pin Description (32M)

| Pin Name | Description |
|-------------------|---|
| A_{21} to A_0 | Address Input: A_{20} to A_0 for 32M, A_{21} to A_0 for 64M |
| CE1# | Chip Enable (Low Active) |
| CE2 | Chip Enable (High Active) |
| WE# | Write Enable (Low Active) |
| OE# | Output Enable (Low Active) |
| UB# | Upper Byte Control (Low Active) |
| LB# | Lower Byte Control (Low Active) |
| CLK | Clock Input |
| ADV# | Address Valid Input (Low Active) |
| WAIT# | Wait Signal Output |
| DQ_{16-9} | Upper Byte Data Input/Output |
| DQ_{8-1} | Lower Byte Data Input/Output |
| V_{DD} | Power Supply |
| V_{SS} | Ground |

Functional Description

| Write (Lower Byte) | | | X | | | | | | L | H | Valid | Input Valid | Invalid | High-Z |
| Write (Word) | | | X | | | | | | L | L | Valid | Input Valid | Input Valid | High-Z |
| Power Down (Note 2) | | | L | | | | | | X | X | X | X | X | X |

Legend: L = V_{IL} , H = V_{IH} , X can be either V_{IL} or V_{IH} , High-Z = High Impedance.

Notes:

- Should not be kept at this logic condition longer than $1\mu s$.
- Power Down mode can be entered from Standby state and all DQ pins are in High-Z state. Data retention depends on the selection of Partial Size. Refer to the "Power Down" section in the Functional Description for details.
- "L" for address pass through and "H" for address latch on the rising edge of ADV#.
- OE# can be V_{IL} during Write operation if the following conditions are satisfied:
 - Write pulse is initiated by CE1# (refer to CE1# Controlled Write timing), or cycle time of the previous operation cycle is satisfied.
 - OE# stays V_{IL} during Write cycle
- Can be either V_{IL} or V_{IH} but must be valid before Read or Write.
- Output is either Valid or High-Z depending on the level of UB# and LB# input.

Functional Description

Synchronous Operation (Burst Mode)

| Mode | CE2 | CE1# | CLK | ADV# | WE# | OE# | LB# | UB# | A ₂₁₋₀ | DQ ₈₋₁ | DQ ₁₆₋₉ | WAIT# |
|--|-----|------|-------------|------|------------|------------|------------|------------|-------------------|-----------------------|-----------------------|------------------|

| Burst Write Suspend (Note 1) | | | VE (Note 3) | | H (Note 5) | | | | | Input Invalid | Input Invalid | High (Note 12) |
| Terminate Burst Read | | VE | X | | H | X | | | | High-Z | High-Z | High-Z |
| Terminate Burst Write | | VE | X | | X | H | | | | High-Z | High-Z | High-Z |
| Power Down (Note 2) | L | X | X | X | X | X | X | X | X | High-Z | High-Z | High-Z |

Legend: L = V_{IL} , H = V_{IH} , X can be either V_{IL} or V_{IH} , VE = Valid Edge, PELP = Positive Edge of Low Pulse, High-Z = High Impedance.

Notes:

- Should not be kept this logic condition longer than the specified time of 8 μ s for 32M and 4 μ s for 64M.
- Power Down mode can be entered from Standby state and all DQ pins are in High-Z state. Data retention depends on the selection of Partial Size. Refer to the "Power Down" section for details.F
- Valid clock edge shall be set on either positive or negative edge through CR Set. CLK must be started and stable prior to memory access.
- Can be either V_{IL} or V_{IH} except for the case the both of OE# and WE# are V_{IL} . It is prohibited to bring the both of OE# and WE# to V_{IL} .
- When device is operating in "WE# Single Clock Pulse Control" mode, WE# is don't care once write operation is determined by WE# Low Pulse at the beginning of write access together with address latching. Write suspend feature is not supported in "WE# Single Clock Pulse Control" mode.
- Can be either V_{IL} or V_{IH} but must be valid before Read or Write is determined. And once UB# and LB# inputs are determined, they must not be changed until the end of burst.
- Once valid address is determined, input address must not be changed during ADV#=L.
- If OE#=L, output is either Invalid or High-Z depending on the level of UB# and LB# input. If WE#=L, Input is Invalid. If OE#=WE#=H, output is High-Z.
- Output is either Valid or High-Z depending on the level of UB# and LB# input.
- Input is either Valid or Invalid depending on the level of UB# and LB# input.
- Output is either High-Z or Invalid depending on the level of OE# and WE# input.
- Keep the level from previous cycle except for suspending on last data. Refer to "WAIT# Output Function" for details.
- WAIT# output is driven in High level during write operation.

State Diagrams

Initial/Standby State

Figure 38. Initial Standby State Diagram

Asynchronous Operation State

Figure 39. Asynchronous Operation State Diagram

Synchronous Operation State

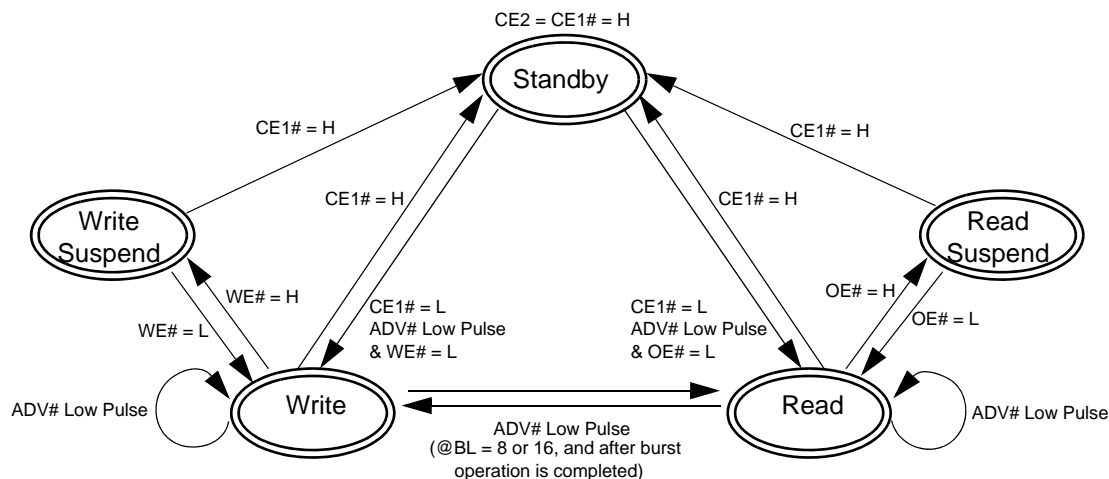

Figure 40. Synchronous Operation Diagram

Notes:

- Assumes all the parameters specified in the "AC Characteristics" section are satisfied. Refer to the "Functional Description" section, "AC Characteristics" section, and the "Timing Diagrams" section for details. RP (Reset to Page) mode is available only for 64M.

Functional Description

This device supports asynchronous page read & normal write operation and synchronous burst read & burst write operation for faster memory access and features three kinds of power down modes for power saving as a user configurable option.

Power-up

It is required to follow the power-up timing to start executing proper device operation. Refer to POWER-UP Timing. After Power-up, the device defaults to asynchronous page read & normal write operation mode with sleep power down feature.

Configuration Register

The Configuration Register (CR) is used to configure the type of device function among optional features. Each selection of features is set through CR Set sequence after Power-up. If CR Set sequence is not performed after power-up, the device is configured for asynchronous operation with sleep power down feature as default configuration.

CR Set Sequence

The CR Set requires total 6 read/write operations with unique address. Between each read/write operation requires the device to be in standby mode. The following table shows the detail sequence.

| Cycle # | Operation | Address | Data |
|---------|-----------|----------------|-----------------|
| 1st | Read | 3FFFFFFh (MSB) | Read Data (RDa) |
| 2nd | Write | 3FFFFFFh | RDa |

| Cycle # | Operation | Address | Data |
|---------|-----------|-------------|-----------------|
| 3rd | Write | 3FFFFFFh | RDa |
| 4th | Write | 3FFFFFFh | X |
| 5th | Write | 3FFFFFFh | X |
| 6th | Read | Address Key | Read Data (RDb) |

The first cycle is to read from most significant address (MSB).

The second and third cycle are to write to MSB. If the second or third cycle is written into the different address, the CR Set is cancelled and the data written by the second or third cycle is valid as a normal write operation. It is recommended to write back the data (RDa) read by first cycle to MSB in order to secure the data.

The forth and fifth cycle is to write to MSB. The data of forth and fifth cycle is don't-care. If the forth or fifth cycle is written into different address, the CR Set is also cancelled but write data may not be written as normal write operation.

The last cycle is to read from specific address key for mode selection. And read data (RDb) is invalid.

Once this CR Set sequence is performed from an initial CR set to the other new CR set, the written data stored in memory cell array may be lost. So, CR Set sequence should be performed prior to regular read/write operation if necessary to change from default configuration.

Address Key

The address key has the following format.

| Address Pin | Register Name | Function | Key | Description | | Note |
|-------------|---------------|------------------|------------|---|--------------------------|------|
| | | | | 32M | 64M | |
| A21 | — | — | 1 | — | Unused bits must be 1 | 1 |
| A20-A19 | PS | Partial Size | 00 | 8M Partial | 16M Partial | |
| | | | 01 | 4M Partial | 8M Partial | |
| | | | 10 | Reserved for future use | | 2 |
| | | | 11 | Sleep [Default] | | |
| A18-A16 | BL | Burst Length | 000 to 001 | Reserved for future use | | 2 |
| | | | 010 | 8 words | | |
| | | | 011 | 16 words | | |
| | | | 100 to 110 | Reserved for future use | | 2 |
| | | | 111 | Continuous | | |
| A15 | M | Mode | 0 | Synchronous Mode (Burst Read / Write) | | 3 |
| | | | 1 | Asynchronous Mode [Default] (Page Read / Normal Write) | | 4 |
| A14-A12 | RL | Read Latency | 000 | Reserved for future use | | 2 |
| | | | 001 | 3 clocks | | |
| | | | 010 | 4 clocks | | |
| | | | 011 | 5 clocks | | |
| | | | 100 | Reserved for future use | 6 clocks | |
| | | | 101 to 111 | Reserved for future use | | 2 |
| A11 | BS | Burst Sequence | 0 | Reserved for future use | | 2 |
| | | | 1 | Sequential | | |
| A10 | SW | Single Write | 0 | Burst Read & Burst Write | | |

| | | | 1 | Rising Clock Edge | | |
| A8 | RP | Reset to Page | 0 | Unused bits must be 1 | Reset to Page mode | 6 |
| | | | 1 | | Remain the previous mode | |
| A7 | WC | Write Control | 0 | WE# Single Clock Pulse Control without Write Suspend Function | | 5 |
| | | | 1 | WE# Level Control with Write Suspend Function | | |
| A6-A0 | — | — | 1 | Unused bits must be 1 | | 1 |

Notes:

1. A21 and A6 to A0 must be all "1" in any case.
2. It is prohibited to apply this key.
3. If M=0, all the registers must be set with appropriate Key input at the same time.
4. If M=1, PS must be set with appropriate Key input at the same time. Except for PS, all the other key inputs must be "1".
5. Burst Read & Single Write is not supported at WE# Single Clock Pulse Control.
6. Effective only when PS=11. RP (Reset to Page) mode is available only for 64M.

Power Down

The Power Down is low power idle state controlled by CE2. CE2 Low drives the device in power down mode and maintains low power idle state as long as CE2 is kept Low. CE2 High resumes the device from power down mode. These devices have three power down mode. These can be programmed by series of read/write operations. Each mode has following features.

| 32M | | | 64M | | |
|-----------------|---------------------|--------------------|-----------------|---------------------|---------------------|
| Mode | Data Retention Size | Retention Address | Mode | Data Retention Size | Retention Address |
| Sleep (default) | No | N/A | Sleep (default) | No | N/A |
| 4M Partial | 4M bit | 000000h to 03FFFFh | 8M Partial | 8M bit | 000000h to 07FFFFh |
| 8M Partial | 8M bit | 000000h to 07FFFFh | 16M Partial | 16M bit | 000000h to 0FFFFFFh |

The default state is Sleep and it is the lowest power consumption but all data will be lost once CE2 is brought to Low for Power Down. It is not required to program to Sleep mode after power-up.

64M supports Reset to Page (RP) mode. When RP=0, Power Down comprehends a function to reset the device to default configuration (asynchronous mode). After resuming from power down mode, the device is back in default configurations. This is effective only when PS is set on Sleep mode. When Partial mode is selected, RP=0 is not effective.

Burst Read/Write Operation

Synchronous burst read/write operation provides faster memory access that synchronized to microcontroller or system bus frequency. Configuration Register Set is required to perform burst read & write operation after power-up. Once CR Set sequence is performed to select synchronous burst mode, the device is configured to synchronous burst read/write operation mode with corresponding RL and BL that is set through CR Set sequence together with operation mode. In order to perform synchronous burst read & write operation, it is required to control new signals, CLK, ADV# and WAIT# that Low Power SRAMs don't have.

Figure 41. Burst Read Operation

Figure 42. Burst Write Operation

CLK Input Function

The CLK is input signal to synchronize memory to microcontroller or system bus frequency during synchronous burst read & write operation. The CLK input increments device internal address counter and the valid edge of CLK is referred for latency counts from address latch, burst write data latch, and burst read data out. During synchronous operation mode, CLK input must be supplied except for standby state and power down state. CLK is don't care during asynchronous operation.

ADV# Input Function

The ADV# is input signal to indicate valid address presence on address inputs. It is applicable to synchronous operation as well as asynchronous operation. ADV# input is active during CE1#=L and CE1#=H disables ADV# input. All addresses are determined on the positive edge of ADV#.

During synchronous burst read/write operation, ADV#=H disables all address inputs. Once ADV# is brought to High after valid address latch, it is inhibited to bring ADV# Low until the end of burst or until burst operation is terminated. ADV# Low pulse is mandatory for synchronous burst read/write operation mode to latch the valid address input.

During asynchronous operation, ADV#=H also disables all address inputs. ADV# can be tied to Low during asynchronous operation and it is not necessary to control ADV# to High.

WAIT# Output Function

The WAIT# is output signal to indicate data bus status when the device is operating in synchronous burst mode.

During burst read operation, WAIT# output is enabled after specified time duration from OE#=L or CE1#=L whichever occurs last. WAIT# output Low indicates data out at next clock cycle is invalid, and WAIT# output becomes High one clock cycle prior to valid data out. During OE# read suspend, WAIT# output doesn't indicate data bus status but carries the same level from previous clock cycle (kept High) except for read suspend on the final data output. If final read data out is suspended, WAIT# output become high impedance after specified time duration from OE#=H.

In case of continuous burst read operation of 32M, an additional output delay may occur when a burst sequence crosses it's device-row boundary. The WAIT# output indicates this delay. Refer to the "[Burst Length](#)" section for the additional delay cycles in details.

During burst write operation, WAIT# output is enabled to High level after specified time duration from WE#=L or CE1#=L whichever occurs last and kept High for entire write cycles including WE# write suspend. The actual write data latching starts on the appropriate clock edge with respect to Valid Clock Edge, Read Latency and Burst Length. During WE# write suspend, WAIT# output doesn't indicate data bus status but carries the same level from previous clock cycle (kept High) except for write suspend on the final data input. If final write data in is suspended, WAIT# output become high impedance after specified time duration from WE#=H.

The burst write operation of 32M and the both burst read/write operation of 64M are always started after fixed latency with respect to Read Latency set in CR.

When the device is operating in asynchronous mode, WAIT# output is always in High Impedance.

Latency

Read Latency (RL) is the number of clock cycles between the address being latched and first read data becoming available during synchronous burst read operation. It is set through CR Set sequence after power-up. Once specific RL is set through CR Set sequence, write latency, that is the number of clock cycles between address being latched and first write data being latched, is automatically set to RL-1. The burst operation is always started after fixed latency with respect to Read Latency set in CR. RL=6 is available only for 64M.

Figure 43. Read Latency Diagram

Address Latch by ADV#

The ADV# indicates valid address presence on address inputs. During synchronous burst read/write operation mode, all the address are determined on the positive edge of ADV# when CE1#=L. The specified minimum value of ADV#=L setup time and hold time against valid edge of clock where RL count begin must be satisfied for appropriate RL counts. Valid address must be determined with specified setup time against either the negative edge of ADV# or negative edge of CE1# whichever comes late. And the determined valid address must not be changed during ADV#=L period.

Burst Length

Burst Length is the number of word to be read or write during synchronous burst read/write operation as the result of a single address latch cycle. It can be set on 8, 16 words boundary or continuous for entire address through CR Set sequence. The burst type is sequential that is incremental decoding scheme within a boundary address. Starting from initial address being latched, device internal address counter assign +1 to the previous address until reaching the end of boundary address and then wrap round to least significant address (=0). After completing read data out or write data latch for the set burst length, operation automatically ended except for continuous burst length. When continuous burst length is set, read/write is endless unless it is terminated by the positive edge of CE1#.

During continuous burst read of 32M, an additional output delay may occur when a burst sequence cross it's device-row boundary. This is the case when A0 to A6 of starting address is either 7Dh, 7Eh, or 7Fh as shown in the following table. The WAIT# signal indicates this delay. The 64M device has no additional output delay.

| Start Address (A6-A0) | Read Address Sequence | | |
|--------------------------|-----------------------|---------------------|------------------------------------|
| | BL = 8 | BL = 16 | Continuous |
| 00h | 00-01-02-...-06-07 | 00-01-02-...-0E-0F | 00-01-02-03-04-... |
| 01h | 01-02-03-...-07-00 | 01-02-03-...-0F-00 | 01-02-03-04-05-... |
| 02h | 02-03-...-07-00-01 | 02-03-...-0F-00-01 | 02-03-04-05-06-... |
| 03h | 03-...-07-00-01-02 | 03-...-0F-00-01-02 | 03-04-05-06-07-... |
| ... | ... | ... | ... |
| 7Ch | 7C-...-7F-78-...-7B | 7C-...-7F-70-...-7B | 7C-7D-7E-7F-80-81-... |
| 7Dh | 7D-7E-7F-78-...-7C | 7D-7E-7F-70-...-7C | 7D-7E-7F- WAIT -80-81-... |
| 7Eh | 7E-7F-78-79-...-7D | 7E-7F-70-71-...-7D | 7E-7F- WAIT-WAIT -80-81-... |
| 7Fh | 7F-78-79-7A-...-7E | 7F-70-71-72-...-7E | 7F- WAIT-WAIT-WAIT -80-81 |

Note: Read address in Hexadecimal.

Single Write

Single Write is synchronous write operation with Burst Length =1. The device can be configured either to "Burst Read & Single Write" or to "Burst Read & Burst Write" through CR set sequence. Once the device is configured to "Burst Read & Single Write" mode, the burst length for synchronous write operation is always fixed 1 regardless of BL values set in CR, while burst length for read is in accordance with BL values set in CR.

Write Control

The device has two types of WE# signal control method, "WE# Level Control" and "WE# Single Clock Pulse Control", for synchronous write operation. It is configured through CR set sequence.

Figure 44. Write Controls

Burst Read Suspend

Burst read operation can be suspended by OE# High pulse. During burst read operation, OE# brought to High suspends burst read operation. Once OE# is brought to High with the specified set up time against clock where the data being suspended, the device internal counter is suspended, and the data output become high impedance after specified time duration. It is inhibited to suspend the first data out at the beginning of burst read.

OE# brought to Low resumes burst read operation. Once OE# is brought to Low, data output become valid after specified time duration, and internal address counter is reactivated. The last data out being suspended as the result of OE#=H and first data out as the result of OE#=L are from the same address.

In order to guarantee to output last data before suspension and first data after resumption, the specified minimum value of OE#=L hold time and setup time against clock edge must be satisfied respectively.

Figure 45. Burst Read Suspend Diagram

Burst Write Suspend

Burst write operation can be suspended by WE# High pulse. During burst write operation, WE# brought to High suspends burst write operation. Once WE# is brought to High with the specified set up time against clock where the data being suspended, device internal counter is suspended, data input is ignored. It is inhibited to suspend the first data input at the beginning of burst write.

WE# brought to Low resumes burst write operation. Once WE# is brought to Low, data input become valid after specified time duration, and internal address counter is reactivated. The write address of the cycle where data being suspended and the first write address as the result of WE#=L are the same address.

In order to guarantee to latch the last data input before suspension and first data input after resumption, the specified minimum value of WE#=L hold time and setup time against clock edge must be satisfied respectively. Burst write suspend function is available when the device is operating in WE# level controlled burst write only.

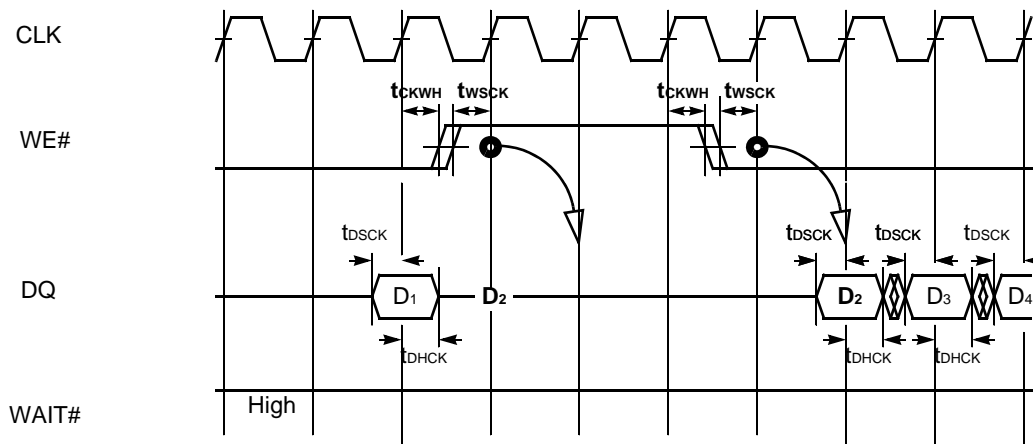

Figure 46. Burst Write Suspend Diagram

Burst Read Termination

Burst read operation can be terminated by CE1# brought to High. If BL is set on Continuous, burst read operation is continued endless unless terminated by

CE1#=H. It is inhibited to terminate burst read before first data out is completed. In order to guarantee last data output, the specified minimum value of CE1#=L hold time from clock edge must be satisfied. After termination, the specified minimum recovery time is required to start new access.

Figure 47. Burst Read Termination Diagram

Burst Write Termination

Burst write operation can be terminated by CE1# brought to High. If BL is set on Continuous, burst write operation is continued endless unless terminated by CE1#=H. It is inhibited to terminate burst write before first data in is completed. In order to guarantee last write data being latched, the specified minimum values of CE1#=L hold time from clock edge must be satisfied. After termination, the specified minimum recovery time is required to start new access.

Figure 48. Burst Write Termination Diagram

Absolute Maximum Ratings

| Item | Symbol | Value | Unit |
|---|----------------------|--------------|--------------------|
| Voltage of V_{DD} Supply Relative to V_{SS} | V_{DD} | -0.5 to +3.6 | V |
| Voltage at Any Pin Relative to V_{SS} | V_{IN} , V_{OUT} | -0.5 to +3.6 | V |
| Short Circuit Output Current | I_{OUT} | ± 50 | mA |
| Storage temperature | T_{STG} | -55 to +125 | $^{\circ}\text{C}$ |

WARNING: Semiconductor devices can be permanently damaged by application of stress (voltage, current, temperature, etc.) in excess of absolute maximum ratings. Do not exceed these ratings.

Recommended Operating Conditions (See Warning Below)

| Parameter | Symbol | 32M | | 64M | | Unit |
|-----------------------------------|----------|---------------------|---------------------|---------------------|---------------------|--------------------|
| | | Min | Max | Min | Max | |
| Supply Voltage | V_{DD} | 1.65 | 1.95 | 1.7 | 1.95 | V |
| | V_{SS} | 0 | 0 | 0 | 0 | V |
| High Level Input Voltage (Note 1) | V_{IH} | $V_{DD} \times 0.8$ | $V_{DD}+0.2$ | $V_{DD} \times 0.8$ | $V_{DD}+0.2$ | V |
| High Level Input Voltage (Note 2) | V_{IL} | -0.3 | $V_{DD} \times 0.2$ | -0.3 | $V_{DD} \times 0.2$ | V |
| Ambient Temperature | T_A | -30 | 85 | -30 | 85 | $^{\circ}\text{C}$ |

Notes:

- Maximum DC voltage on input and I/O pins are $V_{DD}+0.2\text{V}$. During voltage transitions, inputs may positive overshoot to $V_{DD}+1.0\text{V}$ for periods of up to 5 ns.
- Minimum DC voltage on input or I/O pins are -0.3V . During voltage transitions, inputs may negative overshoot V_{SS} to -1.0V for periods of up to 5ns.

WARNING: Recommended operating conditions are normal operating ranges for the semiconductor device. All the device's electrical characteristics are warranted when operated within these ranges.

Always use semiconductor devices within the recommended operating conditions. Operation outside these ranges may adversely affect reliability and could result in device failure.

No warranty is made with respect to uses, operating conditions, or combinations not represented on the data sheet.

Package Pin Capacitance

Test conditions: $T_A = 25^{\circ}\text{C}$, $f = 1.0\text{ MHz}$

| Symbol | Description | Test Setup | Typ | Max | Unit |
|-----------|-------------------------------|----------------------|-----|-----|------|
| C_{IN1} | Address Input Capacitance | $V_{IN} = 0\text{V}$ | — | 5 | pF |
| C_{IN2} | Control Input Capacitance | $V_{IN} = 0\text{V}$ | — | 5 | pF |
| C_{IO} | Data Input/Output Capacitance | $V_{IO} = 0\text{V}$ | — | 8 | pF |

| CE1# High Pulse Width | t_{CP} | 15 | — | 15 | — | ns | |

Notes:

1. Maximum value is applicable if CE#1 is kept at Low without change of address input of A3 to A21.
2. Address should not be changed within minimum t_{RC} .
3. The output load 50pF with 50ohm termination to $V_{DD} * 0.5$ V.

4. *The output load 5pF without any other load.*
5. *Applicable to A3 to A21 when CE1# is kept at Low.*
6. *Applicable only to A0, A1 and A2 when CE1# is kept at Low for the page address access.*
7. *In case Page Read Cycle is continued with keeping CE1# stays Low, CE1# must be brought to High within 4 μ s. In other words, Page Read Cycle must be closed within 4 μ s.*
8. *t_{VPL} is specified from the negative edge of either CE1# or ADV# whichever comes late. The sum of t_{VPL} and t_{VPH} must be equal or greater than t_{RC} for each access.*
9. *Applicable to address access when at least two of address inputs are switched from previous state.*
10. *t_{RC(min)} and t_{PRC(min)} must be satisfied.*
11. *If actual value of t_{WHOL} is shorter than specified minimum values, the actual t_{AA} of following Read may become longer by the amount of subtracting actual value from specified minimum value.*

Write Operation

| Parameter | Symbol | 32M | | 64M | | Unit | Notes |
|---|------------|------|------|------|------|------|-------|
| | | Min. | Max. | Min. | Max. | | |
| Write Cycle Time | t_{WC} | 70 | 1000 | 70 | 1000 | ns | 1, 2 |
| Address Setup Time | t_{AS} | 0 | — | 0 | — | ns | 3 |
| ADV# Low Pulse Width | t_{VPL} | 10 | — | 10 | — | ns | 4 |
| ADV# High Pulse Width | t_{VPH} | 15 | — | 15 | — | ns | |
| Address Setup Time to ADV# High | t_{ASV} | 5 | — | 5 | — | ns | |
| Address Hold Time from ADV# High | t_{AHV} | 10 | — | 5 | — | ns | |
| CE1# Write Pulse Width | t_{CW} | 45 | — | 45 | — | ns | 3 |
| WE# Write Pulse Width | t_{WP} | 45 | — | 45 | — | ns | 3 |
| LB# / UB# Write Pulse Width | t_{BW} | 45 | — | 45 | — | ns | 3 |
| LB# / UB# Byte Mask Setup Time | t_{BS} | -5 | — | -5 | — | ns | 5 |
| LB# / UB# Byte Mask Hold Time | t_{BH} | -5 | — | -5 | — | ns | 6 |
| CE1# Write Recovery Time | t_{WRC} | 15 | — | 15 | — | ns | 7 |
| Write Recovery Time | t_{WR} | 15 | 1000 | 15 | 1000 | ns | 7 |
| CE1# High Pulse Width | t_{CP} | 15 | — | 15 | — | ns | |
| WE# High Pulse Width | t_{WHP} | 15 | 1000 | 15 | 1000 | ns | |
| LB# / UB# High Pulse Width | t_{BHP} | 15 | 1000 | 15 | 1000 | ns | |
| Data Setup Time | t_{DS} | 15 | — | 15 | — | ns | |
| Data Hold Time | t_{DH} | 0 | — | 0 | — | ns | |
| OE# High to CE1# Low Setup Time for Write | t_{OHCL} | -5 | — | -5 | — | ns | 8 |
| OE# High to Address Setup Time for Write | t_{OES} | 0 | — | 0 | — | ns | 9 |
| LB# / UB# Write Pulse Overlap | t_{BWO} | 30 | — | 30 | — | ns | |

Notes:

1. Maximum value is applicable if CE1# is kept at Low without any address change.
2. Minimum value must be equal or greater than the sum of write pulse (t_{CW} , t_{WP} or t_{BW}) and write recovery time (t_{WR}).
3. Write pulse is defined from High to Low transition of CE1#, WE#, or LB# / UB#, whichever occurs last.
4. t_{VPL} is specified from the negative edge of either CE#1 or ADV# whichever comes late. The sum of t_{VPL} and t_{VPH} must be equal or greater than t_{WC} for each access.
5. Applicable for byte mask only. Byte mask setup time is defined to the High to Low transition of CE1# or WE# whichever occurs last.
6. Applicable for byte mask only. Byte mask hold time is defined from the Low to High transition of CE1# or WE# whichever occurs first.
7. Write recovery is defined from Low to High transition of CE1#, WE#, or LB# / UB#, whichever occurs first.
8. If OE# is Low after minimum t_{OHCL} , read cycle is initiated. In other words, OE# must be brought to High within 5ns after CE1# is brought to Low. Once read cycle is initiated, new write pulse should be input after minimum t_{RC} is met.
9. If OE# is Low after new address input, read cycle is initiated. In other word, OE# must be brought to High at the same time or before new address valid. Once read cycle is initiated, new write pulse should be input after minimum t_{RC} is met and data bus is in High-Z.

Synchronous Operation - Clock Input (Burst Mode)

| Parameter | | Symbol | 32M | | 64M | | Unit | Notes |
|----------------------|--------|-----------|------|------|------|------|------|-------|
| | | | Min. | Max. | Min. | Max. | | |
| Clock Period | RL = 6 | t_{CK} | N/A | | 13 | — | ns | 1 |
| | RL = 5 | | 15 | — | 15 | — | ns | |
| | RL = 4 | | 20 | — | 18 | — | ns | |
| | RL = 3 | | 30 | — | 30 | — | ns | |
| Clock High Time | | t_{CKH} | 5 | — | 4 | — | ns | |
| Clock Low Time | | t_{CKL} | 5 | — | 4 | — | ns | |
| Clock Rise/Fall Time | | t_{CKT} | — | 3 | — | 3 | ns | 2 |

Notes:

1. Clock period is defined between valid clock edges.
2. Clock rise/fall time is defined between V_{IH} Min. and V_{IL} Max.

Synchronous Operation - Address Latch (Burst Mode)

| Parameter | | Symbol | 32M | | 64M | | Unit | Notes |
|--|-----------|------------|------|------|------|------|------|-------|
| | | | Min. | Max. | Min. | Max. | | |
| Address Setup Time to ADV# Low | | t_{ASVL} | -5 | — | -5 | — | ns | 1 |
| Address Setup Time to CE1# Low | | t_{ASCL} | -5 | — | -5 | — | ns | 2 |
| Address Hold Time from ADV# High | | t_{AHV} | 10 | — | 5 | — | ns | |
| ADV# Low Pulse Width | | t_{VPL} | 10 | — | 10 | — | ns | 3 |
| ADV# Low Setup Time to CLK | RL = 6, 5 | t_{VSCK} | 7 | — | 5 | — | ns | 4 |
| | RL = 4, 3 | | | — | 7 | — | ns | 4 |
| CE1 Low Setup Time to CLK | RL = 6, 5 | t_{CLCK} | 7 | — | 5 | — | ns | 4 |
| | RL = 4, 3 | | | — | 7 | — | ns | 4 |
| ADV# Low Hold Time from CLK | | t_{CKVH} | 1 | — | 1 | — | ns | 4 |
| Burst End ADV# High Hold Time from CLK | | t_{VHVL} | 15 | — | 13 | — | ns | |

Notes:

1. t_{ASCL} is applicable if CE1# is brought to Low after ADV# is brought to Low.
2. t_{ASVL} is applicable if ADV# is brought to Low after CE1# is brought to Low.
3. t_{VPL} is specified from the negative edge of either CE1# or ADV# whichever comes late.
4. Applicable to the 1st valid clock edge.

Synchronous Read Operation (Burst Mode)

| Parameter | Symbol | 32M | | 64M | | Unit | Notes | |
|---------------------------------------|---------------|-----------|------|------|------|------|-------|---|
| | | Min. | Max. | Min. | Max. | | | |
| Burst Read Cycle Time | t_{RCB} | — | 8000 | — | 4000 | ns | | |
| CLK Access Time | RL = 6, 5 | — | 12 | — | 10 | ns | 1 | |
| | RL = 4, 3 | | | — | 12 | ns | 1 | |
| Output Hold Time from CLK | t_{CKQX} | 3 | — | 3 | — | ns | 1 | |
| CE1# Low to WAIT# Low | t_{CLTL} | 5 | 20 | 5 | 20 | ns | 1 | |
| OE# Low to WAIT# Low | t_{OLTL} | 0 | 20 | 0 | 20 | ns | 1, 2 | |
| ADV# Low to WAIT# Low | t_{VLTTL} | N/A | | 0 | 20 | ns | 1 | |
| CLK to WAIT# Valid Time | t_{CKTV} | — | 12 | — | 10 | ns | 1, 3 | |
| WAIT# Valid Hold Time from CLK | t_{CKTX} | 3 | — | 3 | — | ns | 1 | |
| CE1# Low to Output Low-Z | t_{CLZ} | 5 | — | 5 | — | ns | 4 | |
| OE# Low to Output Low-Z | t_{OLZ} | 10 | — | 10 | — | ns | 4 | |
| LB#, UB# Low to Output Low-Z | t_{BLZ} | 0 | — | 0 | — | ns | 4 | |
| CE1# High to Output High-Z | t_{CHZ} | — | 14 | — | 20 | ns | 1 | |
| OE# High to Output High-Z | t_{OHZ} | — | 14 | — | 20 | ns | 1 | |
| LB#, UB# High to Output High-Z | t_{BHZ} | — | 14 | — | 20 | ns | 1 | |
| CE1# High to WAIT High-Z | t_{CHTZ} | — | 20 | — | 20 | ns | 1 | |
| OE# High to WAIT High-Z | t_{OHTZ} | — | 20 | — | 20 | ns | 1 | |
| OE# Low Setup Time to 1st Data-out | t_{OLQ} | 30 | — | 30 | — | ns | | |
| UB#, LB# Setup Time to 1st Data-out | t_{BLQ} | 30 | — | 26 | — | ns | 5 | |
| OE# Setup Time to CLK | t_{OSCK} | 5 | — | 5 | — | ns | | |
| OE# Hold Time from CLK | t_{CKOH} | 5 | — | 5 | — | ns | | |
| Burst End CE1# Low Hold Time from CLK | t_{CKCLH} | 5 | — | 5 | — | ns | | |
| Burst End UB#, LB# Hold Time from CLK | t_{CKBH} | 5 | — | 5 | — | ns | | |
| Burst Terminate Recovery Time | BL=8, 16 | t_{TRB} | 30 | — | 26 | — | ns | 6 |
| | BL=Continuous | | 70 | — | 70 | — | ns | 6 |

Notes:

1. The output load 50pF with 50ohm termination to $V_{DD} * 0.5 V$.
2. WAIT# drives High at the beginning depending on OE# falling edge timing.
3. t_{CKTV} is guaranteed after t_{OLTL} (max) from OE# falling edge and t_{OSCK} must be satisfied.
4. The output load is 5pF without any other load.
5. Once they are determined, they must not be changed until the end of burst.
6. Defined from the Low to High transition of CE1# to the High to Low transition of either ADV# or CE1# whichever occurs late.

Synchronous Write Operation (Burst Mode)

| Parameter | Symbol | 32M | | 64M | | Unit | Notes | |
|--|---------------|-----------|------|------|------|------|-------|---|
| | | Min. | Max. | Min. | Max. | | | |
| Burst Write Cycle Time | t_{WCB} | — | 8000 | — | 4000 | ns | | |
| Data Setup Time to Clock | t_{DSCK} | 7 | — | 5 | — | ns | | |
| Data Hold Time from CLK | t_{DHCK} | 3 | — | 3 | — | ns | | |
| WE# Low Setup Time to 1st Data In | t_{WLD} | 30 | — | 30 | — | ns | | |
| UB#, LB# Setup Time for Write | t_{BS} | -5 | — | -5 | — | ns | 1 | |
| WE# Setup Time to CLK | t_{WSCK} | 5 | — | 5 | — | ns | | |
| WE# Hold Time from CLK | t_{CKWH} | 5 | — | 5 | — | ns | | |
| CE1# Low to WAIT# High | t_{CLTH} | 5 | 20 | 5 | 20 | ns | 2 | |
| WE# Low to WAIT# High | t_{WLTH} | 0 | 20 | 0 | 20 | ns | 2 | |
| CE1# High to WAIT# High-Z | t_{CHTZ} | — | 20 | — | 20 | ns | 2 | |
| WE# High to WAIT# High-Z | t_{WHTZ} | — | 20 | — | 20 | ns | 2 | |
| Burst End CE1# Low Hold Time from CLK | t_{CKCLH} | 5 | — | 5 | — | ns | | |
| Burst End CE1# High Setup Time to next CLK | t_{CHCK} | 5 | — | 5 | — | ns | | |
| Burst End UB#, LB# Hold Time from CLK | t_{CKBH} | 5 | — | 5 | — | ns | | |
| Burst Write Recovery Time | t_{WRB} | 30 | | 26 | | ns | | |
| Burst Terminate Recovery Time | BL=8, 16 | t_{TRB} | 30 | — | 26 | — | ns | 3 |
| | BL=Continuous | t_{TRB} | 70 | — | 70 | — | ns | 4 |

Notes:

1. Defined from the valid input edge to the High to Low transition of either ADV#, CE1#, or WE#, whichever occurs last. And once they are determined, they must not be changed until the end of burst.
2. The output load 50pF with 50ohm termination to $V_{DD} * 0.5$ V.
3. Defined from the valid clock edge where last data-in being latched at the end of burst write to the High to Low transition of either ADV# or CE1# whichever occurs late for the next access.
4. Defined from the Low to High transition of CE1# to the High to Low transition of either ADV# or CE1# whichever occurs late for the next access.

Power Down Parameters

| Parameter | Symbol | 32M | | 64M | | Unit | Notes |
|--|-------------|------|------|------|------|---------|-------|
| | | Min. | Max. | Min. | Max. | | |
| CE2 Low Setup Time for Power Down Entry | t_{CSP} | 20 | — | 10 | — | ns | |
| CE2 Low Hold Time after Power Down Entry | t_{C2LP} | 70 | — | 70 | — | ns | |
| CE2 Low Hold Time for Reset to Asynchronous Mode | t_{C2LPR} | N/A | | 50 | — | μ s | 1 |
| CE1# High Hold Time following CE2 High after Power Down Exit [SLEEP mode only] | t_{CHH} | 300 | — | 300 | — | μ s | 2 |
| CE1# High Hold Time following CE2 High after Power Down Exit [not in SLEEP mode] | t_{CHHP} | 70 | — | 70 | — | μ s | 3 |
| CE1# High Setup Time following CE2 High after Power Down Exit | t_{CHS} | 0 | — | 0 | — | ns | 2 |

Notes:

1. Applicable when $RP=0$ (Reset to Page mode). RP (Reset to Page) mode is available only for 64M.
2. Applicable also to power-up.
3. Applicable when Partial mode is set.

Other Timing Parameters

| Parameter | Symbol | 32M | | 64M | | Unit | Notes |
|--|------------|------|------|------|------|---------|-------|
| | | Min. | Max. | Min. | Max. | | |
| CE1 High to OE Invalid Time for Standby Entry | t_{CHOX} | 10 | — | 10 | — | ns | |
| CE1 High to WE Invalid Time for Standby Entry | t_{CHWX} | 10 | — | 10 | — | ns | 1 |
| CE2 Low Hold Time after Power-up | t_{C2LH} | 50 | — | 50 | — | μ s | |
| CE1 High Hold Time following CE2 High after Power-up | t_{CHH} | 300 | — | 300 | — | μ s | |
| Input Transition Time | t_T | 1 | 25 | 1 | 25 | ns | 2 |

Notes:

1. Some data might be written into any address location if $t_{CHWX}(min)$ is not satisfied.
2. Except for clock input transition time.
3. The Input Transition Time (t_T) at AC testing is 5ns for Asynchronous operation and 3ns for Synchronous operation respectively. If actual t_T is longer than 5ns or 3ns specified as AC test condition, it may violate AC specification of some timing parameters. See the "AC Test Conditions" section

AC Test Conditions

| Symbol | Description | Test Setup | Value | Unit | Note |
|-----------|--------------------------------|------------|-------------------------------|------|------|
| V_{IH} | Input High Level | | $V_{DD} * 0.8$ | V | |
| V_{IL} | Input Low Level | | $V_{DD} * 0.2$ | V | |
| V_{REF} | Input Timing Measurement Level | | $V_{DD} * 0.5$ | V | |
| t_T | Input Transition Time | Async. | Between V_{IL} and V_{IH} | 5 | ns |
| | | Sync. | | 3 | ns |

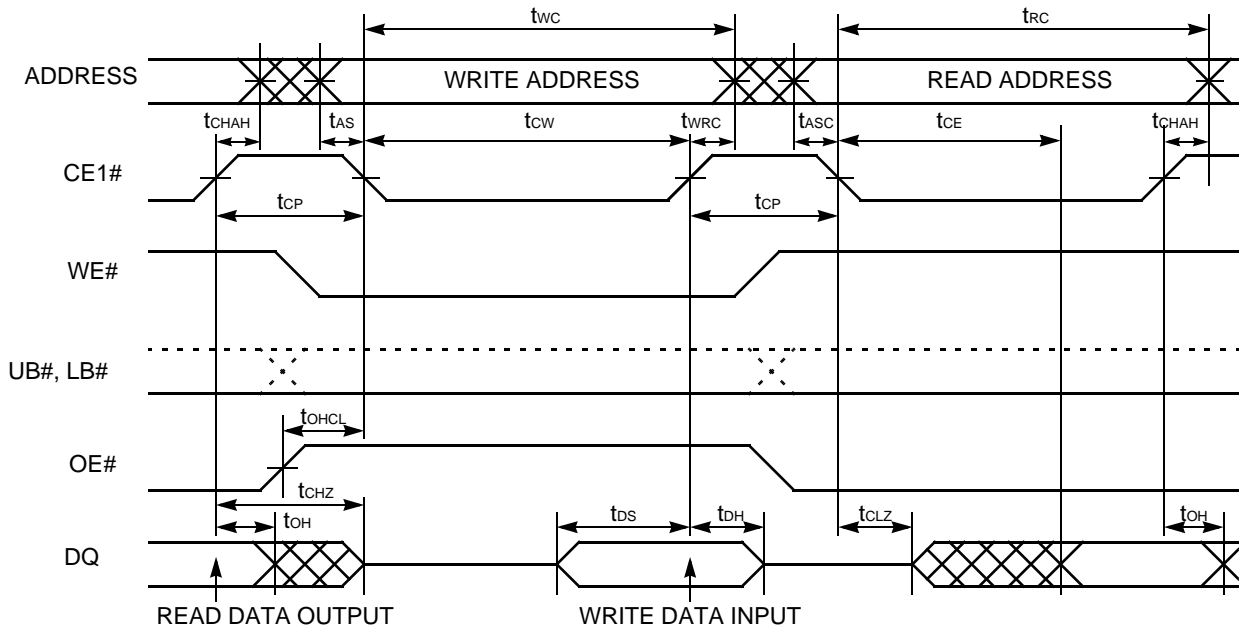

Figure 63. Asynchronous Read / Write Timing #1-1 (CE1# Control)

Notes:

1. This timing diagram assumes CE2=H and ADV#=L.
2. Write address is valid from either CE1# or WE# of last falling edge.

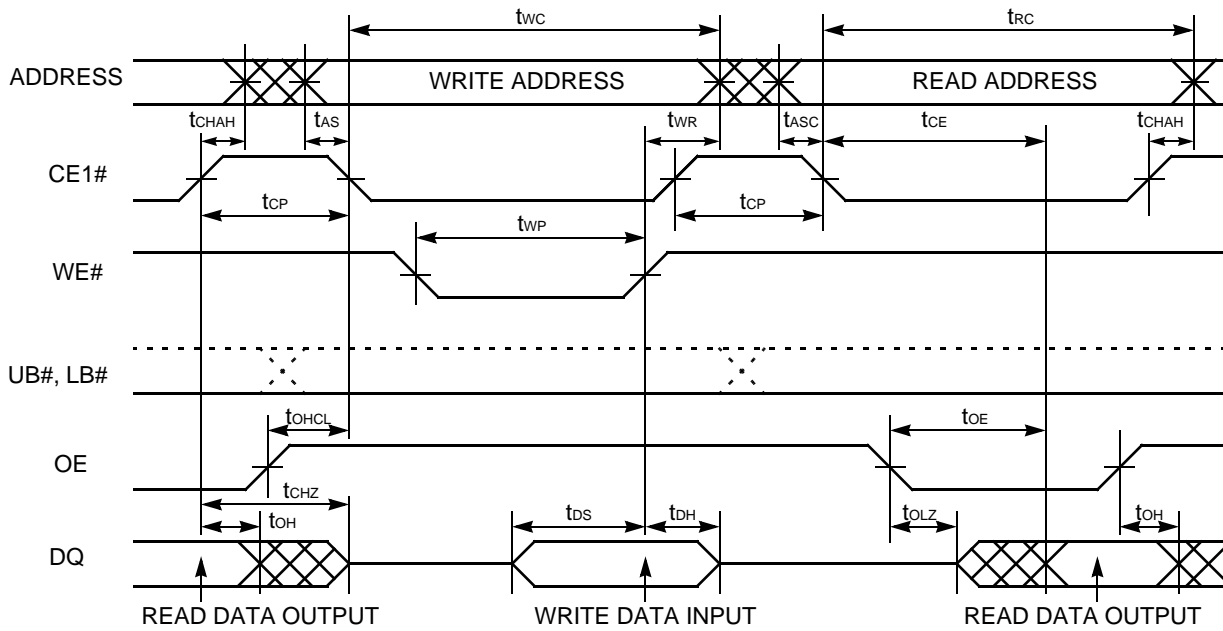

Figure 64. Asynchronous Read / Write Timing #1-2 (CE1# / WE# / OE# Control)

Notes:

1. This timing diagram assumes CE2=H and ADV#=L.
2. OE# can be fixed Low during write operation if it is CE1# controlled write at Read-Write-Read Sequence.

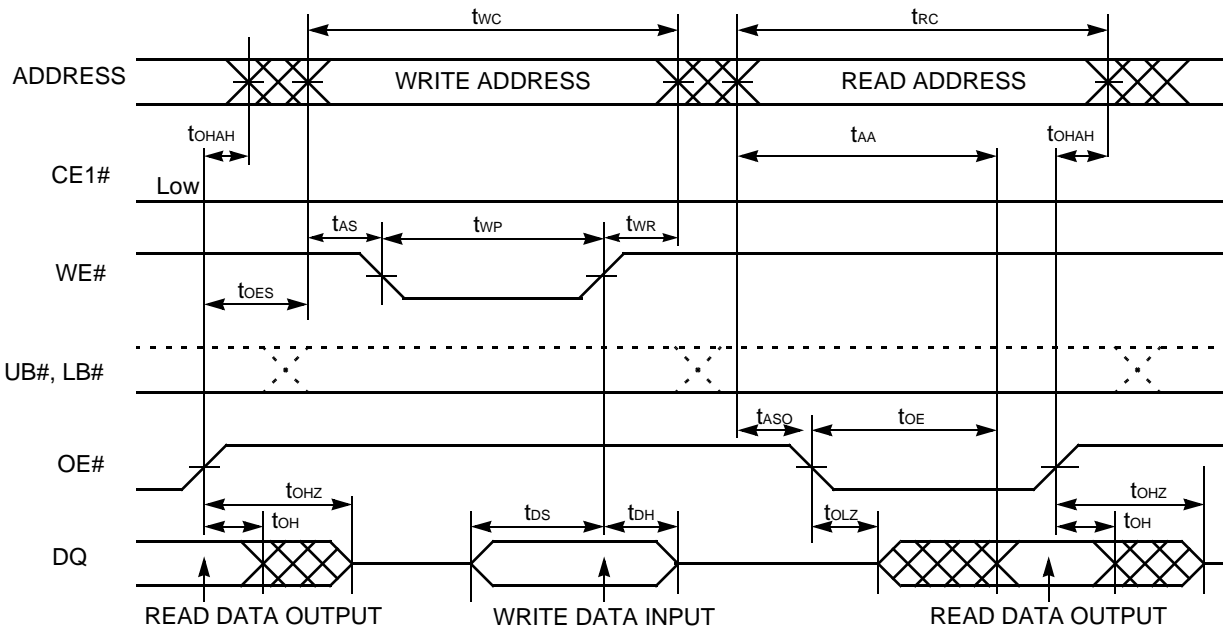

Figure 65. Asynchronous Read / Write Timing #2 (OE#, WE# Control)

Notes:

1. This timing diagram assumes CE2=H and ADV#=L.
2. CE1# can be tied to Low for WE# and OE# controlled operation.

Figure 66. Asynchronous Read / Write Timing #3 (OE,# WE#, LB#, UB# Control)

Notes:

1. This timing diagram assumes CE2=H and ADV#=L.
2. CE1# can be tied to Low for WE# and OE# controlled operation.

Figure 67. Clock Input Timing

Notes:

1. Stable clock input must be required during CE1# = L.
2. t_{CK} is defined between valid clock edges.
3. t_{CKT} is defined between V_{IH} Min. and V_{IL} Max

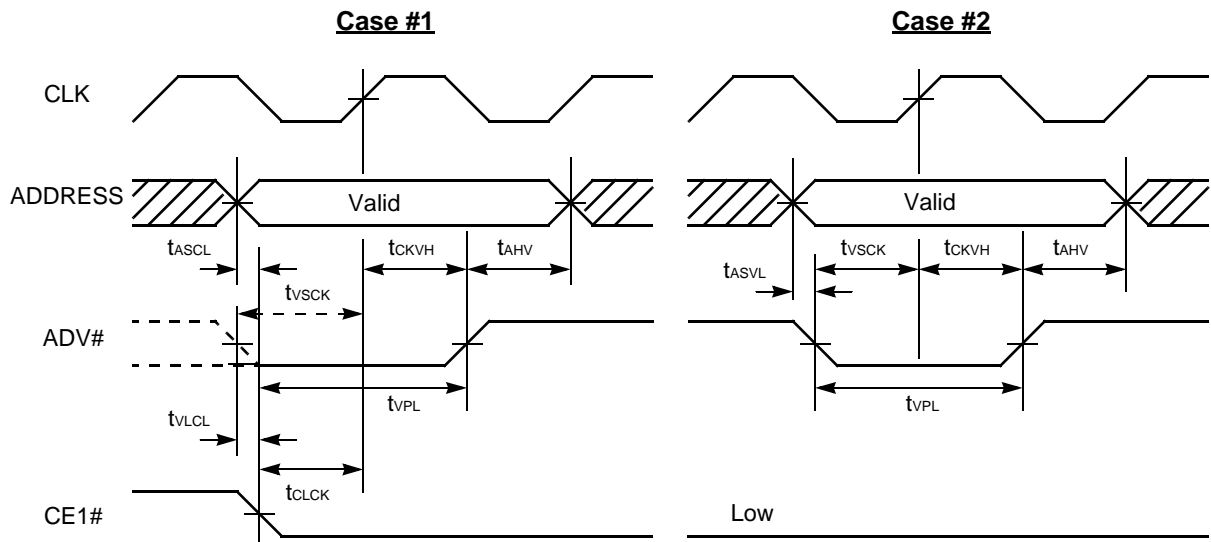

Figure 68. Address Latch Timing (Synchronous Mode)

Notes:

1. Case #1 is the timing when CE1# is brought to Low after ADV# is brought to Low. Case #2 is the timing when ADV# is brought to Low after CE1# is brought to Low.
2. t_{VPL} is specified from the negative edge of either CE1# or ADV# whichever comes late. At least one valid clock edge must be input during ADV#=L.
3. t_{VCK} and t_{CLCK} are applied to the 1st valid clock edge during ADV#=L.

Note: This timing diagram assumes CE2=H, the valid clock edge on rising edge and BL=8 or 16.

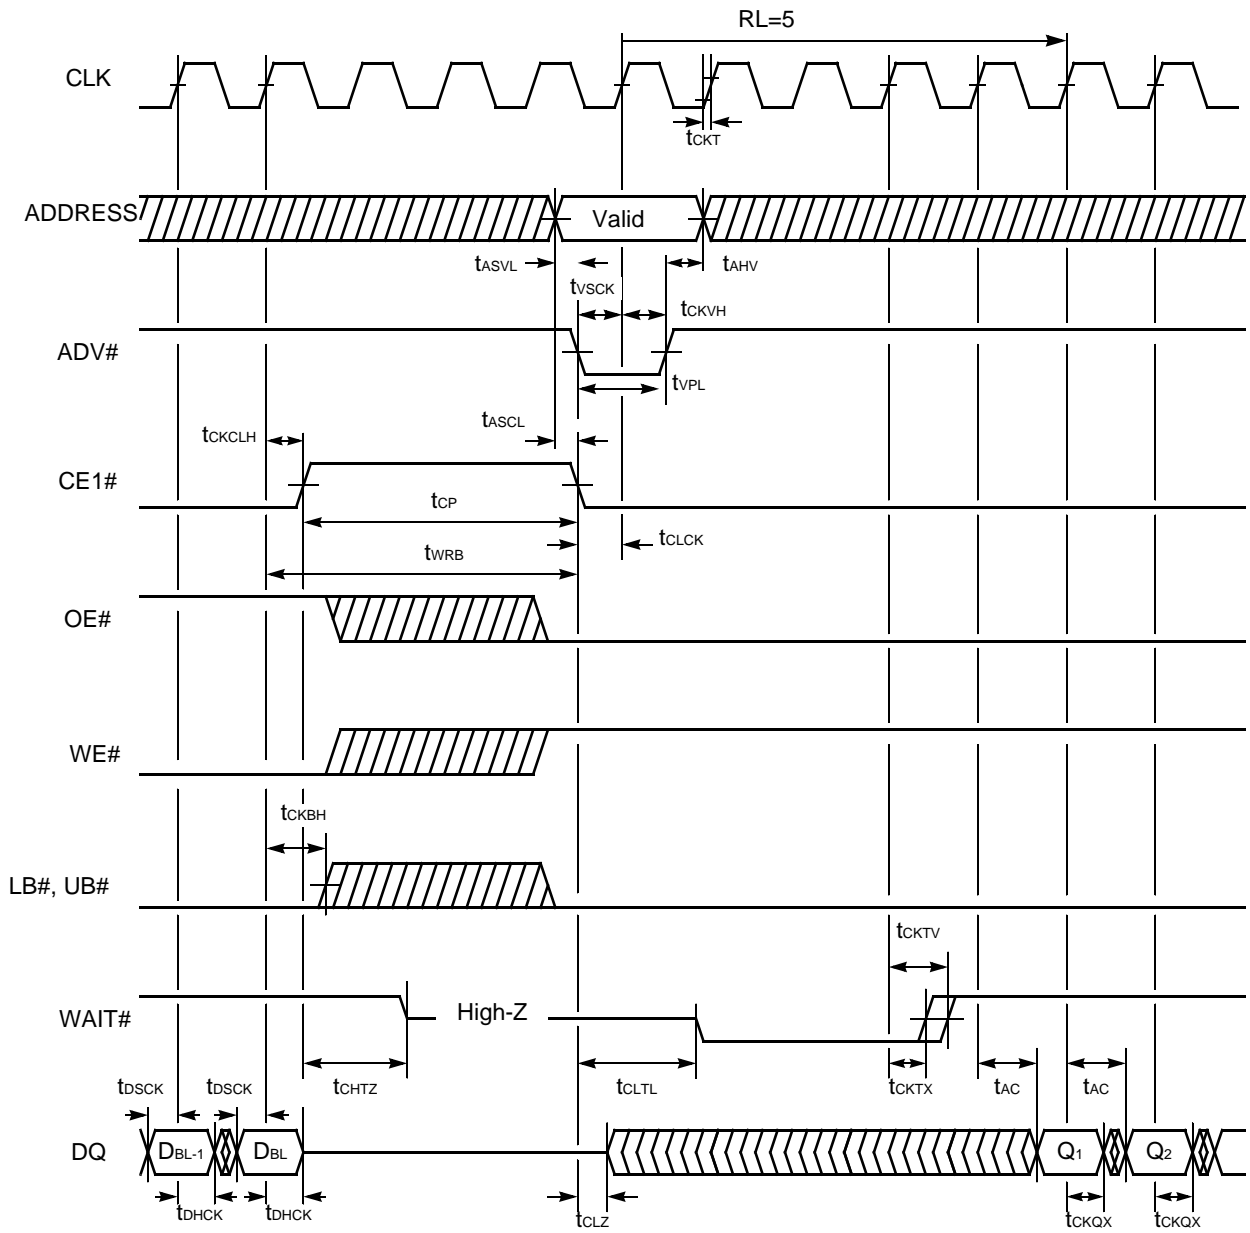

Figure 84. Synchronous Write to Read Timing #1 (CE1# Control)

Note: This timing diagram assumes CE2=H, the valid clock edge on rising edge and BL=8 or 16.

Figure 86. Power-up Timing #1

Note: The t_{C2LH} specifies after V_{DD} reaches specified minimum level.

Figure 87. Power-up Timing #2

Note: The t_{CHH} specifies after V_{DD} reaches specified minimum level and applicable to both CE1# and CE2.

Figure 88. Power Down Entry and Exit Timing

Note: This Power Down mode can be also used as a reset timing if the POWER-UP timing above could not be satisfied and Power-Down program was not performed prior to this reset.

Figure 89. Standby Entry Timing after Read or Write

Note: Both t_{CHOX} and t_{CHWX} define the earliest entry timing for Standby mode. If either of timing is not satisfied, it takes t_{RC} (min) period for Standby mode from CE1# Low to High transition.

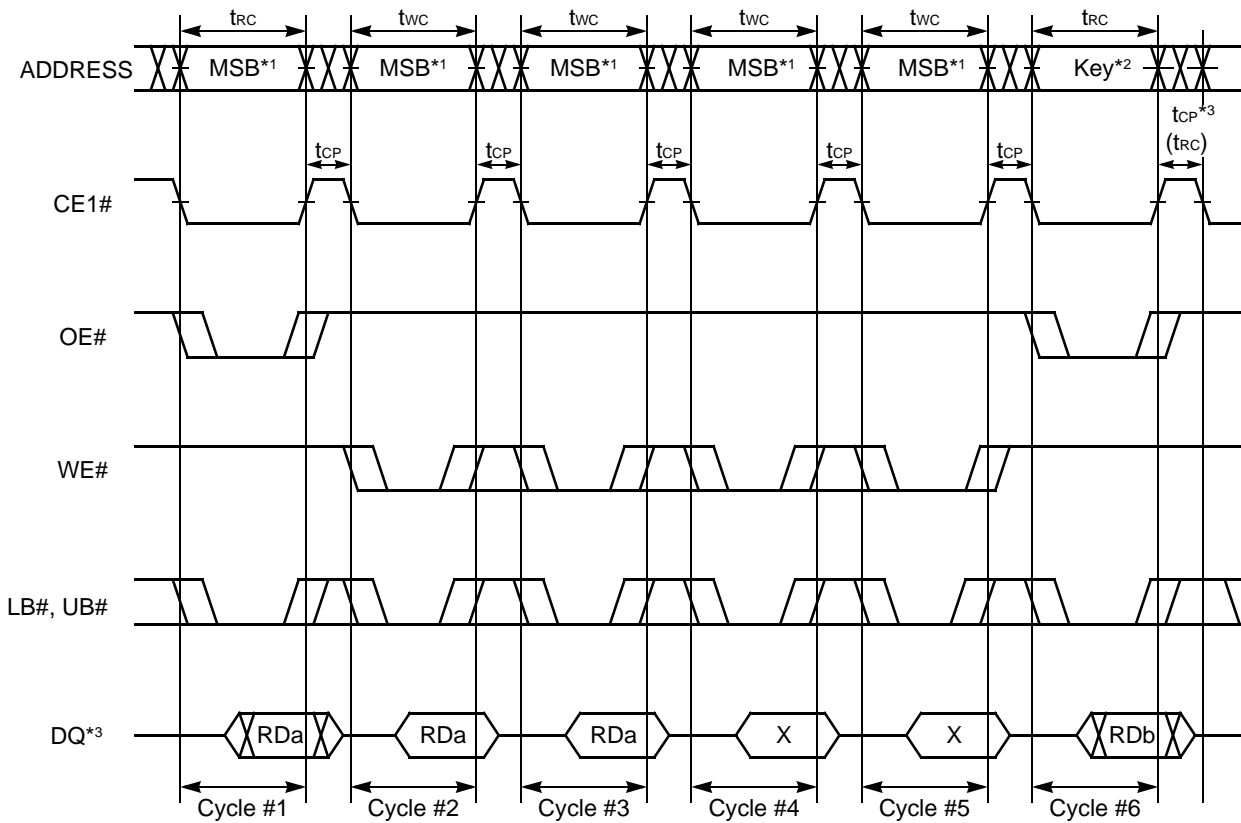

Figure 90. Configuration Register Set Timing #1 (Asynchronous Operation)

Notes:

1. The all address inputs must be High from Cycle #1 to #5.
2. The address key must confirm the format specified in the "Functional Description" section. If not, the operation and data are not guaranteed.
3. After t_{CP} or t_{RC} following Cycle #6, the Configuration Register Set is completed and returned to the normal operation. t_{CP} and t_{RC} are applicable to returning to asynchronous mode and to synchronous mode respectively.
4. Byte read or write is available in addition to Word read or write. At least one byte control signal (LB# or UB#) need to be Low.

Figure 9I. Configuration Register Set Timing #2 (Synchronous Operation)

Notes:

1. The all address inputs must be High from Cycle #1 to #5.
2. The address key must confirm the format specified in the "Functional Description" section. If not, the operation and data are not guaranteed.
3. After t_{TRB} following Cycle #6, the Configuration Register Set is completed and returned to the normal operation.
4. Byte read or write is available in addition to Word read or write. At least one byte control signal (LB# or UB#) need to be Low.

COSMORAM Type I – 1.8 V, 16 Mb

CMOS 1,048,576-Word x 16 Bit pSRAM

PRELIMINARY

Features

- **Asynchronous SRAM Interface**
- **Fast Random Access Time**
 - $t_{CE} = 70 \text{ ns} (-70)$
- **Low Voltage Operating Condition**
 - $V_{DD} = +1.7 \text{ V to } +1.95 \text{ V}$
- **Wide Operating Temperature**
 - $T_A = -30^\circ\text{C to } +85^\circ\text{C}$
- **Byte Control by UB# and LB#**
- **Low Power Consumption**
 - $I_{DDA1} = 20 \text{ mA max}$
 - $I_{DDS1} = 100 \mu\text{A max}$
- **Power Down Mode**

General Description

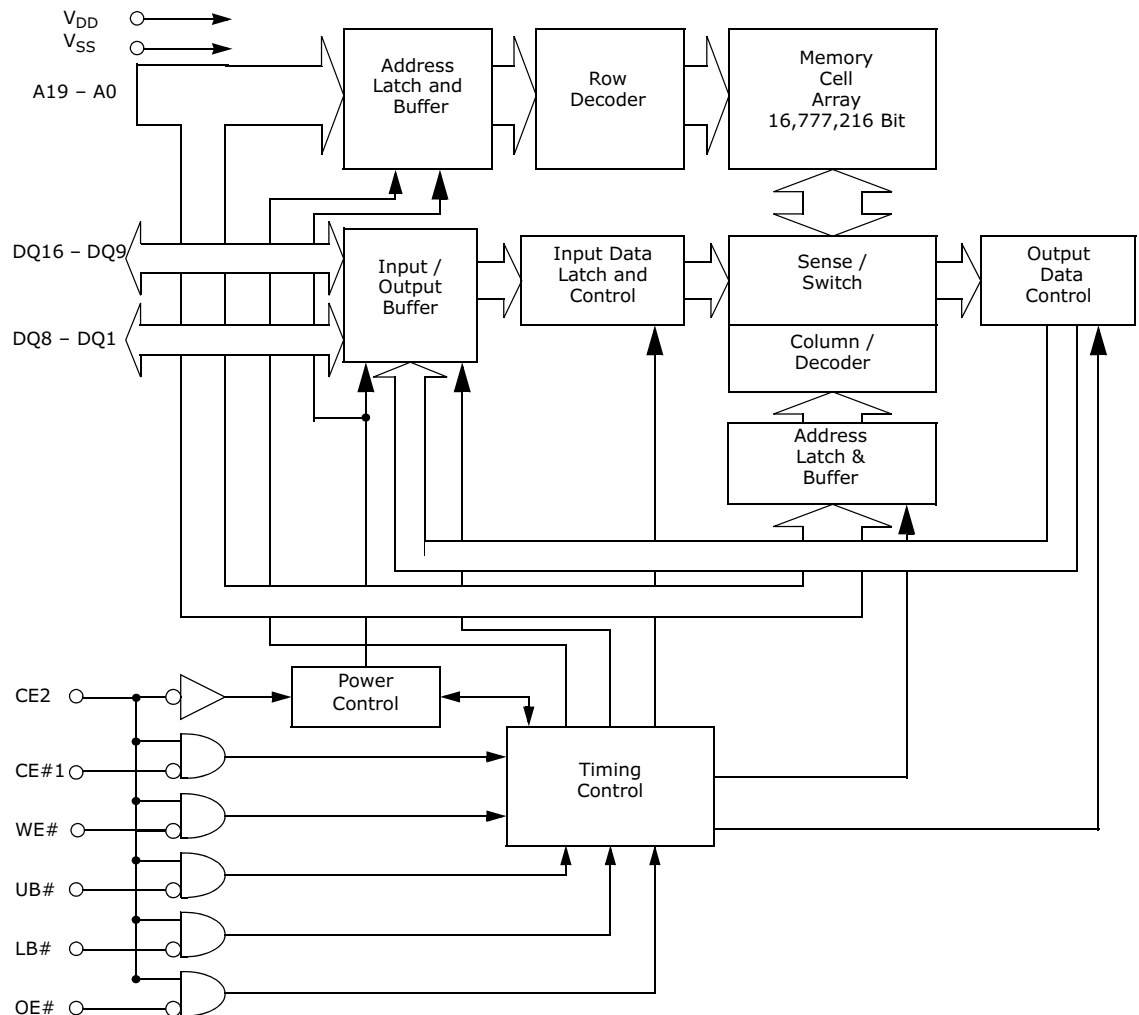

The COSMORAM Type 1 is a CMOS pSRAM with asynchronous Static Random Access Memory (SRAM) interface containing 16,777,216 storages accessible in a 16-bit format. This COSMORAM Type 1 is suited for mobile applications such as Cellular Handset and PDA.

Pin Description

| Pin Name | Description |
|-----------------------------------|---------------------------------|
| A ₁₉ to A ₀ | Address Input |
| CE1# | Chip Enable (Low Active) |
| CE2 | Chip Enable (High Active) |
| WE# | Write Enable (Low Active) |
| OE# | Output Enable (Low Active) |
| UB# | Upper Byte Control (Low Active) |

| Pin Name | Description |
|--------------------|---------------------------------|
| LB# | Lower Byte Control (Low Active) |
| DQ ₁₆₋₉ | Upper Byte Data Input/Output |
| DQ ₈₋₁ | Lower Byte Data Input/Output |
| V _{DD} | Power Supply |
| V _{SS} | Ground |

Block Diagram

Function Truth Table

| Mode | CE2 | CE#1 | WE# | OE# | LB# | UB# | A19-0 | DQ8-1 | DQ16-9 | I _{DD} | Data Retention | | |
|--------------------------|-----|------|-----|-----|-----|-----|----------|--------|--------|------------------|----------------|--------------|--------------|
| Standby (Deselect) | H | H | X | X | X | X | X | High-Z | High-Z | I _{DDs} | Yes | | |
| Output Disable (Note 1) | H | L | H | H | X | X | (Note 3) | High-Z | High-Z | I _{DDA} | | | |
| Output Disable (No Read) | | | | | H | H | Valid | High-Z | High-Z | | | | |
| Read (Upper Byte) | | | | | H | L | H | L | Valid | | | High-Z | Output Valid |
| Read (Lower Byte) | | | | | | | L | H | Valid | | | Output Valid | High-Z |
| Read (Word) | | | | | | | L | L | Valid | | | Output Valid | Output Valid |
| No Write | | | | | L | H | H | H | Valid | | | Invalid | Invalid |
| Write (Upper Byte) | | | | | | | H | L | Valid | | | Invalid | Input Valid |
| Write (Lower Byte) | | | | | | | L | H | Valid | | | Input Valid | Invalid |
| Write (Word) | | | | | | | L | L | Valid | | | Input Valid | Input Valid |
| Power Down (Note 2) | | | L | X | X | X | X | X | X | | | High-Z | High-Z |

Legend: L = V_{IL} , H = V_{IH} , X can be either V_{IL} or V_{IH} , High-Z = High Impedance

Notes:

1. This logic condition should not be kept any longer than 1 μ s.
2. Power Down mode can be entered from Standby state and all DQ pins are in High-Z state.
3. Can be either V_{IL} or V_{IH} but must be valid before Read or Write.

Absolute Maximum Ratings

| Parameter | Symbol | Value | Unit |
|---|------------------------------------|--------------|------|
| Voltage of V _{DD} Supply Relative to V _{SS} | V _{DD} | -0.5 to +3.6 | V |
| Voltage at Any Pin Relative to V _{SS} | V _{IN} , V _{OUT} | -0.5 to +3.6 | V |
| Short Circuit Output Current | I _{OUT} | \pm 50 | mA |
| Storage Temperature | T _{STG} | -55 to +125 | °C |

Note: Semiconductor devices can be permanently damaged by application of stress (voltage, current, temperature, and so on) in excess of absolute maximum ratings. Do not exceed these ratings.

Recommended Operating Conditions

| Parameter | Symbol | Min. | Max. | Unit |
|-----------------------------------|-----------------|----------------------|----------------------|------|
| Supply Voltage | V _{DD} | 1.7 | 1.95 | V |
| | V _{SS} | 0 | 0 | V |
| High Level Input Voltage (Note 1) | V _{IH} | V _{DD} *0.8 | V _{DD} +0.2 | V |
| Low Level Input Voltage (Note 2) | V _{IL} | -0.3 | V _{DD} *0.2 | V |
| Ambient Temperature | T _A | -30 | 85 | °C |

Notes: (Referenced to V_{SS})

1. Maximum DC voltage on input and I/O pins are V_{DD} + 0.2 V. During voltage transitions, inputs may overshoot to V_{DD}+1.0 V for periods of up to 5 ns.
2. Minimum DC voltage on input or I/O pins are -0.3 V. During voltage transitions, inputs may overshoot V_{SS} to -1.0 V for periods of up to 5 ns.)
3. Recommended operating conditions are normal operating ranges for the semiconductor device. All the device electrical characteristics are warranted when operated within these ranges.
4. Always use semiconductor devices within the recommended operating conditions. Operation outside these ranges may affect device reliability and result in device failure.
5. No warranty is made with respect to uses, operating conditions, or combinations not represented on the data sheet.

Package Pin Capacitance

| Symbol | Description | Test Setup | Typ. | Max. | Unit |
|-----------|-------------------------------|---------------|------|------|------|
| C_{IN1} | Address Input Capacitance | $V_{IN} = 0V$ | — | 5 | pF |
| C_{IN2} | Control Input Capacitance | $V_{IN} = 0V$ | — | 5 | pF |
| C_{IO} | Data Input/Output Capacitance | $V_{IO} = 0V$ | — | 8 | pF |

Note: Test conditions: $T_A = 25^\circ C$, $f = 1.0$ MHz

DC Characteristics

| Parameter | Symbol | Test Conditions | Min. | Max. | Unit | | |
|-----------------------------|-------------|--|------------------------------------|------|---------|----|----|
| Input Leakage Current | I_{LI} | $V_{IN} = V_{SS}$ to V_{DD} | -1.0 | +1.0 | μA | | |
| Output Leakage Current | I_{LO} | $V_{OUT} = V_{SS}$ to V_{DD} , Output Disable | -1.0 | +1.0 | μA | | |
| Output High Voltage Level | V_{OH} | $V_{DD} = V_{DD}(\min)$, $I_{OH} = -0.5$ mA | 1.4 | — | V | | |
| Output Low Voltage Level | V_{OL} | $I_{OL} = 1$ mA | — | 0.4 | V | | |
| V_{DD} Power Down Current | I_{DDPS} | $V_{DD} = V_{DD} \max.$, $V_{IN} = V_{IH}$ or V_{IL} , $CE2 \leq 0.2V$ | — | 10 | μA | | |
| V_{DD} Standby Current | $I_{DD S}$ | $V_{DD} = V_{DD} \max.$, $V_{IN} = V_{IH}$ or V_{IL} , $CE\#1 = CE2 = V_{IH}$ | — | 1 | mA | | |
| | $I_{DD S1}$ | $V_{DD} = V_{DD} \max.$, $V_{IN} \leq 0.2V$ or $V_{IN} \geq V_{DD} - 0.2$ V, $CE\#1 = CE2 \geq V_{DD} - 0.2$ V | — | 100 | μA | | |
| V_{DD} Active Current | I_{DDA1} | $V_{DD} = V_{DD} \max.$, $V_{IN} = V_{IH}$ or V_{IL} , $CE\#1 = V_{IL}$ and $CE2 = V_{IH}$, $I_{OUT} = 0$ mA | $t_{RC} / t_{WC} = \text{minimum}$ | | — | 20 | mA |
| | I_{DDA2} | | $t_{RC} / t_{WC} = 1\mu s$ | | — | 3 | mA |

Notes:

1. All voltages are referenced to V_{SS} .
2. DC Characteristics are measured after following power-up timing.
3. I_{OUT} depends on the output load conditions.
4. DC Characteristics apply under recommended operating conditions unless otherwise noted

AC Characteristics

Read Operation

| Parameter (Notes) | Symbol | Value | | Unit |
|--------------------------------------|-------------|-------|------|------|
| | | Min. | Max. | |
| Read Cycle Time (1, 2) | t_{RC} | 80 | 1000 | ns |
| CE#1 Access Time (3) | t_{CE} | — | 70 | ns |
| OE# Access Time (3) | t_{OE} | — | 45 | ns |
| Address Access Time (3, 5) | t_{AA} | — | 70 | ns |
| LB# / UB# Access Time (3) | t_{BA} | — | 30 | ns |
| Output Data Hold Time (3) | t_{OH} | 5 | — | ns |
| CE#1 Low to Output Low-Z (4) | t_{CLZ} | 5 | — | ns |
| OE# Low to Output Low-Z (4) | t_{OLZ} | 0 | — | ns |
| LB# / UB# Low to Output Low-Z (4) | t_{BLZ} | 0 | — | ns |
| CE#1 High to Output High-Z (3) | t_{CHZ} | — | 20 | ns |
| OE# High to Output High-Z (3) | t_{OHZ} | — | 20 | ns |
| LB# / UB# High to Output High-Z (3) | t_{BHZ} | — | 20 | ns |
| Address Setup Time to CE#1 Low | t_{ASC} | -5 | — | ns |
| Address Setup Time to OE# Low | t_{ASO} | 10 | — | ns |
| Address Invalid Time (5) | t_{AX} | — | 10 | ns |
| Address Hold Time from CE#1 High (6) | t_{CHAH} | -5 | — | ns |
| Address Hold Time from OE# High | $t_{OH AH}$ | -5 | — | ns |

| Parameter (Notes) | Symbol | Value | | Unit |
|---------------------------------------|------------|-------|------|------|
| | | Min. | Max. | |
| WE# High to OE# Low Time for Read (7) | t_{WHOL} | 15 | 1000 | ns |
| CE#1 High Pulse Width | t_{CP} | 15 | — | ns |

Notes:

1. Maximum value is applicable if CE#1 is kept at Low without any address change.
2. Address should not be changed within minimum t_{RC} .
3. The output load 50 pF with 50- Ω termination to $V_{DD} * 0.5$ V.
4. The output load 5 pF without any other load.
5. Applicable when CE#1 is kept at Low.
6. t_{RC} (min) must be satisfied.
7. If actual value of t_{WHOL} is shorter than specified minimum values, the actual t_{AA} of following Read may become longer by the amount of subtracting actual value from specified minimum value.
8. AC Characteristics apply under recommended operating conditions unless otherwise noted

Write Operation

| Parameter (Notes) | Symbol | Value | | Unit |
|---|------------|-------|------|------|
| | | Min. | Max. | |
| Write Cycle Time (1, 2) | t_{WC} | 80 | 1000 | ns |
| Address Setup Time (2) | t_{AS} | 0 | — | ns |
| CE#1 Write Pulse Width (3) | t_{CW} | 45 | — | ns |
| WE# Write Pulse Width (3) | t_{WP} | 45 | — | ns |
| LB# / UB# Write Pulse Width (3) | t_{BW} | 45 | — | ns |
| LB# / UB# Byte Mask Setup Time (4) | t_{BS} | -5 | — | ns |
| LB# / UB# Byte Mask Hold Time (5) | t_{BH} | -5 | — | ns |
| Write Recovery Time (6) | t_{WR} | 0 | — | ns |
| CE#1 High Pulse Width | t_{CP} | 15 | — | ns |
| WE# High Pulse Width | t_{WHP} | 15 | 1000 | ns |
| LB# / UB# High Pulse Width | t_{BHP} | 15 | 1000 | ns |
| Data Setup Time | t_{DS} | 20 | — | ns |
| Data Hold Time | t_{DH} | 0 | — | ns |
| OE# High to CE#1 Low Setup Time for Write (7) | t_{OHCL} | -5 | — | ns |
| OE# High to Address Setup Time for Write (8) | t_{OES} | 0 | — | ns |
| LB# and UB# Write Pulse Overlap | t_{BWO} | 20 | — | ns |

Notes:

1. Maximum value is applicable if CE#1 is kept at Low without any address change.
2. Minimum value must be equal or greater than the sum of write pulse (t_{CW} , t_{WP} or t_{BW}) and write recovery time (t_{WRC} , t_{WR} or t_{BR}).
3. Write pulse is defined from High to Low transition of CE#1, WE#, or LB# / UB#, whichever occurs last.
4. Applicable for byte mask only. Byte mask setup time is defined to the High to Low transition of CE#1 or WE# whichever occurs last.
5. Applicable for byte mask only. Byte mask hold time is defined from the Low to High transition of CE#1 or WE# whichever occurs first.
6. Write recovery is defined from Low to High transition of CE#1, WE#, or LB# / UB#, whichever occurs first.
7. If OE# is Low after minimum t_{OHCL} , read cycle is initiated. In other word, OE# must be brought to High within 5 ns after CE#1 is brought to Low. Once read cycle is initiated, new write pulse should be input after minimum t_{RC} is met.
8. If OE# is Low after new address input, read cycle is initiated. In other word, OE# must be brought to High at the same time or before new address valid. Once read cycle is initiated, new write pulse should be input after minimum t_{RC} is met.
9. AC Characteristics apply under recommended operating conditions unless otherwise noted

Power Down Parameters

| Parameter (Notes) | Symbol | Value | | Unit |
|---|------------|-------|------|---------|
| | | Min. | Max. | |
| CE2 Low Setup Time for Power Down Entry | t_{CSP} | 10 | — | ns |
| CE2 Low Hold Time after Power Down Entry | t_{C2LP} | 80 | — | ns |
| CE#1 High Hold Time following CE2 High after Power Down Exit [SLEEP mode only] (See Note) | t_{CHH} | 300 | — | μs |
| CE#1 High Setup Time following CE2 High after Power Down Exit | t_{CHS} | 0 | — | ns |

Note: Applicable also to power-up.

Other Timing Parameters

| Parameter (Notes) | Symbol | Value | | Unit |
|---|------------|-------|------|---------|
| | | Min. | Max. | |
| CE#1 High to OE# Invalid Time for Standby Entry | t_{CHOX} | 10 | — | ns |
| CE#1 High to WE# Invalid Time for Standby Entry (1) | t_{CHWX} | 10 | — | ns |
| CE#1 High Hold Time following CE2 High after Power-up | t_{CHH} | 300 | — | μs |
| Input Transition Time (2) | t_T | 1 | 25 | ns |

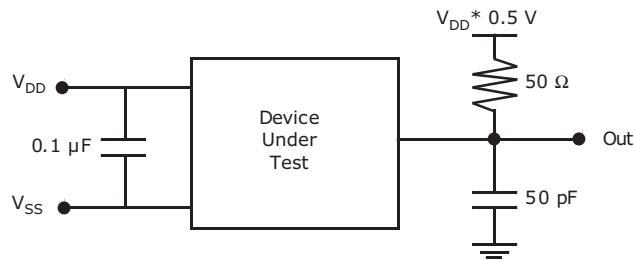

Notes:

1. Some data might be written into any address location if $t_{CHWX}(min)$ is not satisfied.
2. The Input Transition Time (t_T) at AC testing is 5 ns as shown in below. If actual t_T is longer than 5 ns, it may violate AC specification of some timing parameters.

AC Test Conditions

| Symbol | Description | Test Setup | Value | Unit |
|-----------|--------------------------------|-------------------------------|----------------|------|
| V_{IH} | Input High Level | | $V_{DD} * 0.8$ | V |
| V_{IL} | Input Low Level | | $V_{DD} * 0.2$ | V |
| V_{REF} | Input Timing Measurement Level | | $V_{DD} * 0.5$ | V |
| t_T | Input Transition Time | Between V_{IL} and V_{IH} | 5 | ns |

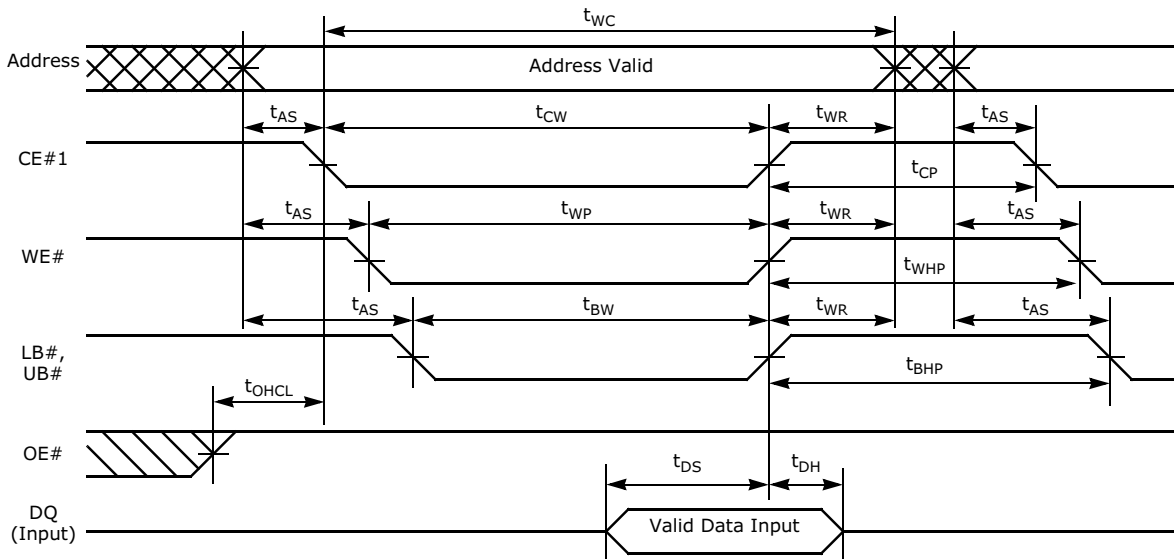

AC Measurement Output Load Circuit

Note: This timing diagram assumes $CE2=H$ and $WE\#=H$.

Figure 94. Read Timing #3 (LB# / UB# Byte Access)

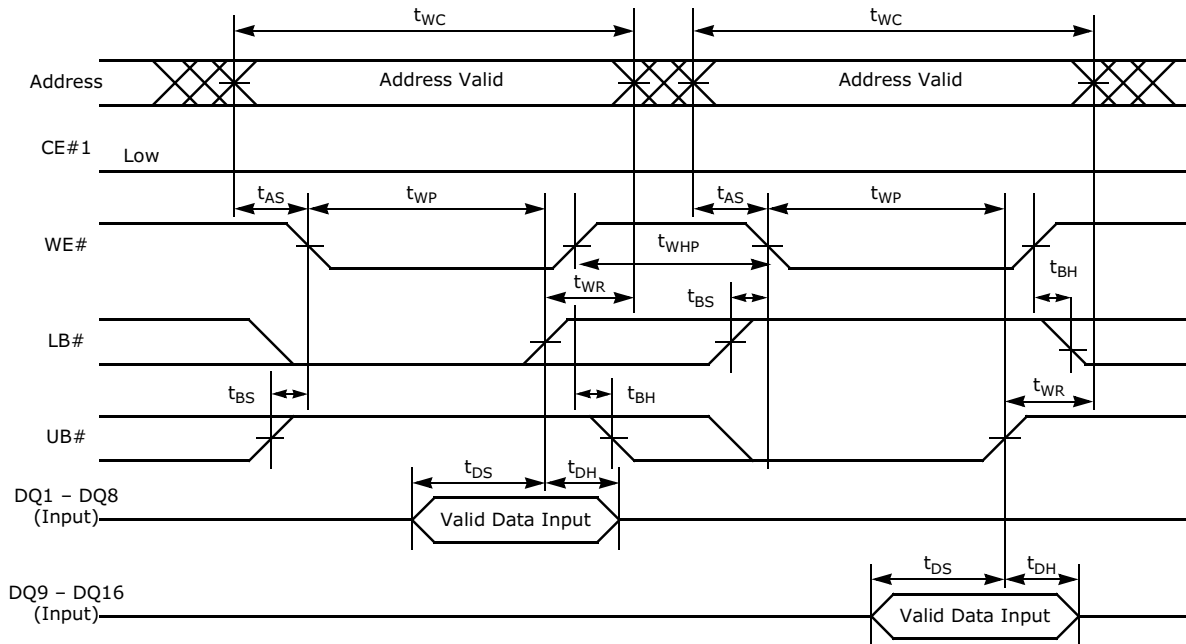

Note: This timing diagram assumes $CE2=H$.

Figure 95. Write Timing #1 (Basic Timing)

Note: This timing diagram assumes CE2=H.

Figure 96. Write Timing #2 (WE# Control)

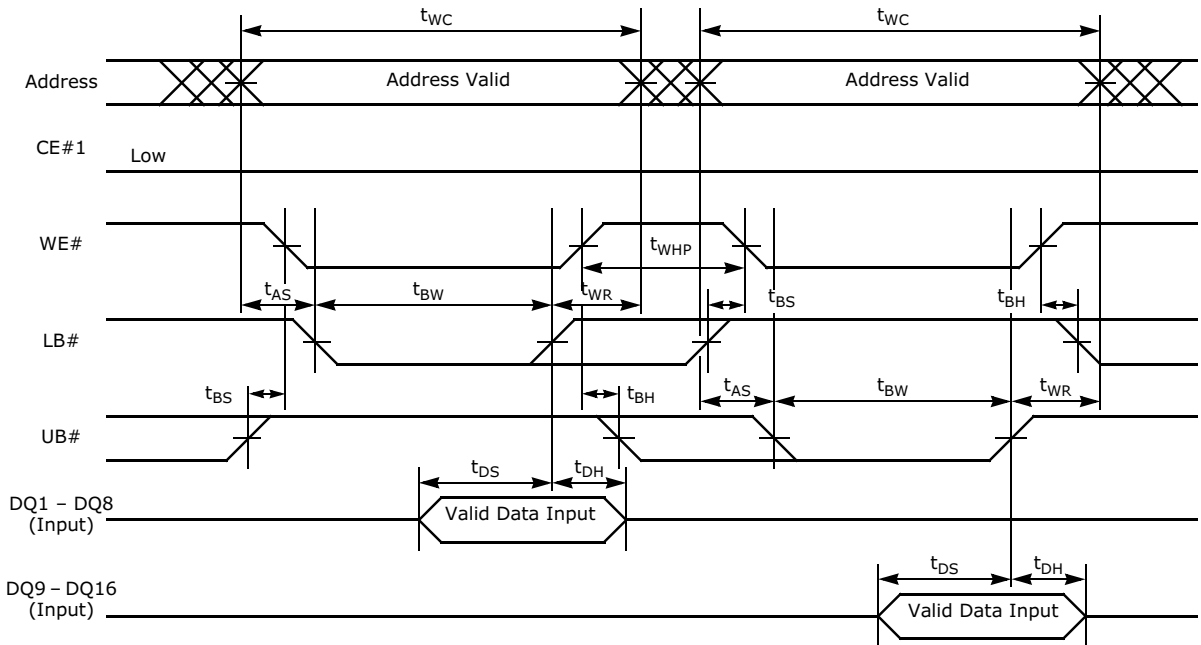

Note: This timing diagram assumes CE2=H and OE#=H.

Figure 97. Write Timing #3 - I (WE# / LB# / UB# Byte Write Control)

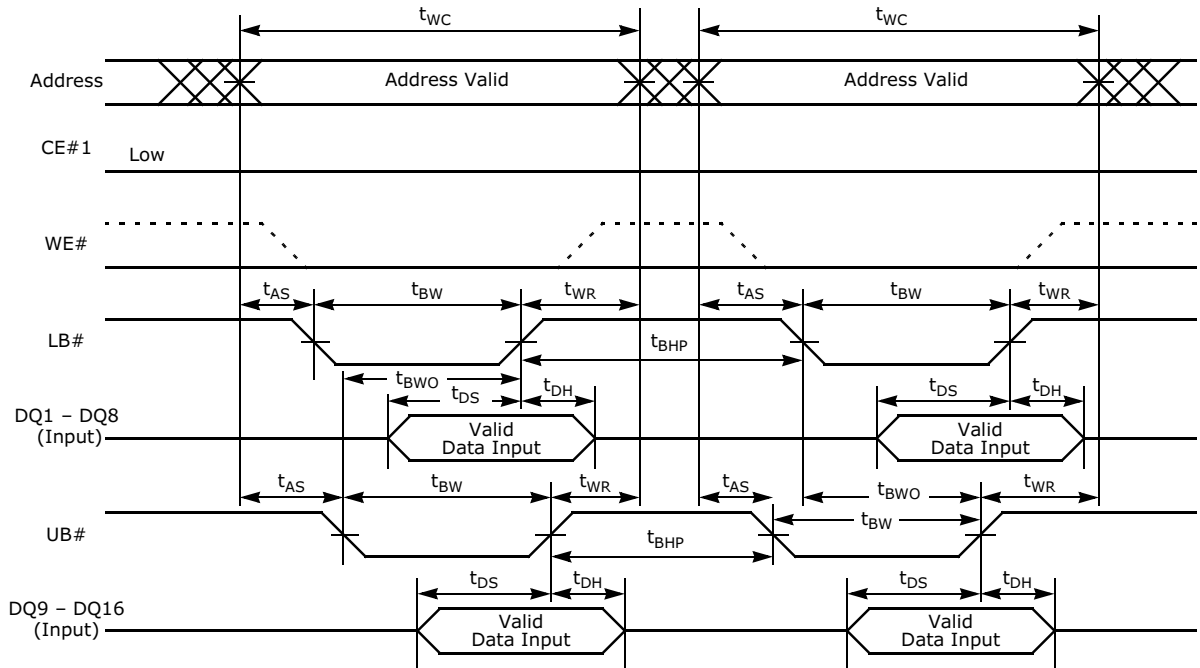

Note: This timing diagram assumes CE2=H and OE#=H.

Figure 98. Write Timing #3 – 2 (WE# / LB# / UB# Byte Write Control)

Note: This timing diagram assumes CE2=H and OE#=H.

Figure 99. Write Timing #3 – 3 (WE# / LB# / UB# Byte Write Control)

Note: This timing diagram assumes CE2=H and OE#=H.

Figure I00. Write Timing #3 - 4 (WE# / LB# / UB# Byte Write Control)

Notes:

1. This timing diagram assumes CE2=H.
2. Write address is valid from either CE#1 or WE# of last falling edge.

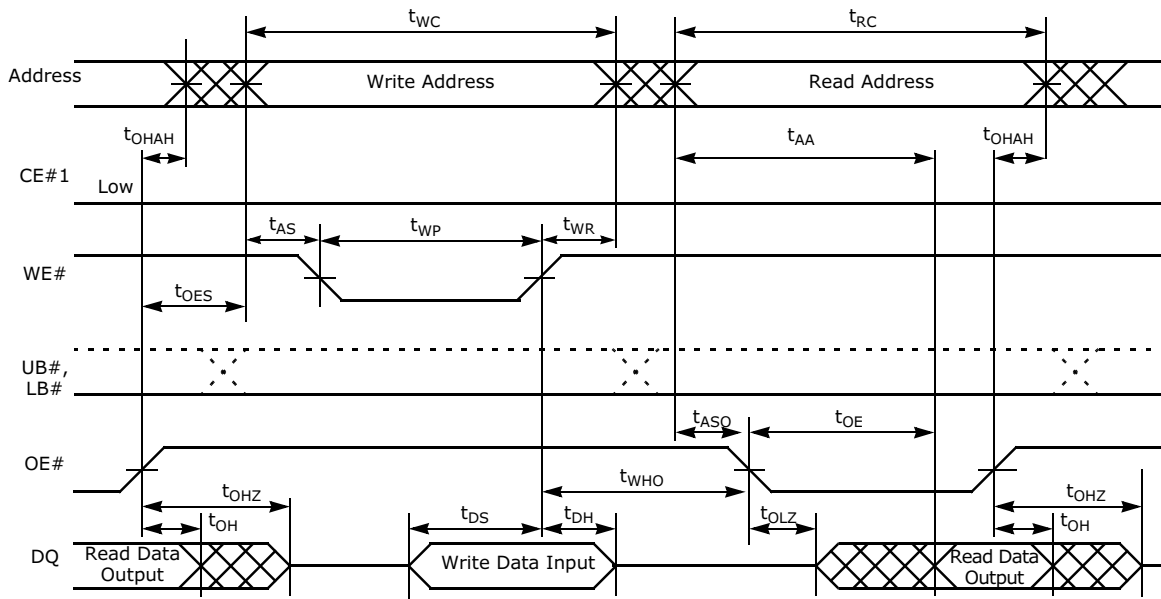

Figure I01. Read / Write Timing #1 - 1 (CE#1 Control)

Notes:

1. This timing diagram assumes CE2=H.
2. OE# can be fixed Low during write operation if it is CE#1 controlled write at Read-Write-Read sequence.

Figure I02. Read / Write Timing #1 – 2 (CE#1 / WE# / OE# Control)

Notes:

1. This timing diagram assumes CE2=H.
2. CE#1 can be tied to Low for WE# and OE# controlled operation.

Figure I03. Read / Write Timing #2 (OE#, WE# Control)

Notes:

1. This timing diagram assumes CE2=H.
2. CE#1 can be tied to Low for WE# and OE# controlled operation.

Figure I04. Read / Write Timing #3 (\overline{OE} , \overline{WE} , \overline{LB} , \overline{UB} Control)

Note: The t_{CHH} specifies after V_{DD} reaches specified minimum level and applicable both CE#1 and CE2.

Figure I05. Power-Up Timing

Note: This Power-down mode can be also used as a reset timing if Power-up timing above could not be satisfied and Power-down program was not performed prior to this reset.

Figure I06. Power-Down Entry and Exit Timing

Note: Both t_{CHOX} and t_{CHWX} define the earliest entry timing for Standby mode. If either of timing is not satisfied, it takes t_{RC} (min) period for Standby mode from CE#1 Low to High transition.

Figure I07. Standby Entry Timing after Read or Write

COSMORAM Type I Revision Summary

Revision A0 (August 2, 2005)

Initial release.

Revision Summary

Revision A0 (October 27, 2004)

Initial release.

Revision A1 (July 5, 2005)

Added TSC080 Package Drawing

Minor corrections and changes

Initial release.

Revision A2 (August 19, 2005)

Added 16 Mb COSMORAM Type 1 module

Colophon

The products described in this document are designed, developed and manufactured as contemplated for general use, including without limitation, ordinary industrial use, general office use, personal use, and household use, but are not designed, developed and manufactured as contemplated (1) for any use that includes fatal risks or dangers that, unless extremely high safety is secured, could have a serious effect to the public, and could lead directly to death, personal injury, severe physical damage or other loss (i.e., nuclear reaction control in nuclear facility, aircraft flight control, air traffic control, mass transport control, medical life support system, missile launch control in weapon system), or (2) for any use where chance of failure is intolerable (i.e., submersible repeater and artificial satellite). Please note that Spansion will not be liable to you and/or any third party for any claims or damages arising in connection with above-mentioned uses of the products. Any semiconductor devices have an inherent chance of failure. You must protect against injury, damage or loss from such failures by incorporating safety design measures into your facility and equipment such as redundancy, fire protection, and prevention of over-current levels and other abnormal operating conditions. If any products described in this document represent goods or technologies subject to certain restrictions on export under the Foreign Exchange and Foreign Trade Law of Japan, the US Export Administration Regulations or the applicable laws of any other country, the prior authorization by the respective government entity will be required for export of those products.
