EVALUATION KIT AVAILABLE

Fully Programmable Serializer/Deserializer with UART/I²C Control Channel

General Description

The MAX9257 serializer pairs with the MAX9258 deserializer to form a complete digital video serial link. The MAX9257/MAX9258 feature programmable parallel data width, parallel clock frequency range, spread spectrum, and preemphasis. An integrated control channel transfers data bidirectionally at power-up during video blanking over the same differential pair used for video data. This feature eliminates the need for external CAN or LIN interface for diagnostics or programming. The clock is recovered from input serial data at MAX9258, hence eliminating the need for an external reference clock.

The MAX9257 serializes 10, 12, 14, 16, and 18 bits with the addition of two encoding bits for AC-coupling. The MAX9258 deserializer links with the MAX9257 to deserialize a maximum of 20 (data + encoding) bits per pixel/parallel clock period for a maximum serial-data rate of 840Mbps. The word length can be adjusted to accommodate a higher pixel/parallel clock frequency. The pixel clock can vary from 5MHz to 70MHz, depending on the serial-word length. Enabling parity adds two parity bits to the serial word. The encoding bits reduce ISI and allow AC-coupling.

The MAX9258 receives programming instructions from the electronic control unit (ECU) during the control channel and transmits to the MAX9257 over the serial video link. The instructions can program or update the MAX9257, MAX9258, or an external peripheral device, such as a camera. The MAX9257 communicates with the peripheral device with I²C or UART.

The MAX9257/MAX9258 operate from a +3.3V core supply and feature separate supplies for interfacing to +1.8V to +3.3V logic levels. These devices are available in 40-lead TQFN or 48-pin LQFP packages. These devices are specified over the -40°C to +105°C temperature range.

Applications

Automotive Cameras

Industrial Cameras

Navigation Systems Display

In-Vehicle Entertainment Systems

Features

- **10/12/14/16/18-Bit Programmable Parallel Data Width**
- **MAX9258 Does Not Require Reference Clock**
- **Parity Protection for Video and Control Channels**
- **Programmable Spread Spectrum**
- **Programmable Rising or Falling Edge for HSYNC, VSYNC, and Clock**
- **Up to 10 Remotely Programmable GPIO on MAX9257**
- **Automatic Resynchronization in Case of Loss of Lock**
- **MAX9257 Parallel Clock Jitter Filter PLL with Bypass**
- **DC-Balanced Coding Allows AC-Coupling**
- **5 Levels of Preemphasis for Up to 20m STP Cable Drive**
- **Integrity Test Using On-Chip Programmable PRBS Generator and Checker**
- **LVDS I/O Meet ISO 10605 ESD Protection (±10kV Contact and ±30kV Air Discharge)**
- **LVDS I/O Meet IEC 61000-4-2 ESD Protection (±8kV Contact and ±20kV Air Discharge)**
- **LVDS I/O Meet ±200V Machine Model ESD Protection**
- **-40°C to +105°C Operating Temperature Range**
- **Space-Saving, 40-Pin TQFN (5mm x 5mm) with Exposed Pad or 48-Pin LQFP Packages**
- **+3.3V Core Supply**

Ordering Information

PART	TEMP RANGE	PIN-PACKAGE
MAX9257GTL/V+	-40°C to +105°C	40 TQFN-EP*
MAX9257GCM/V+	-40°C to +105°C	48 LQFP
MAX9258GCM/V+	-40°C to +105°C	48 LQFP

/V denotes an automotive qualified part.
+Denotes a lead(Pb)-free/RoHS-compliant package.
**EP = Exposed pad.*

Typical Operating Circuit and Pin Configurations appear at end of data sheet.

Fully Programmable Serializer/Deserializer with UART/I²C Control Channel

ABSOLUTE MAXIMUM RATINGS

$V_{CC\_}$ to GND .....-0.5V to +4.0V
Any Ground to Any Ground.....-0.5V to +0.5V
SDI+, SDI-, SDO+, SDO- to GND.....-0.5V to +4.0V
SDO+, SDO- Short Circuit to GND or V_{CCLVDS} .....Continuous
DIN[0:15], GPIO[0:9], PCLK_IN, HSYNC_IN, VSYNC_IN, SCL/TX, SDA/RX, REM to GND .....-0.5V to (V_{CCIO} + 0.5V)
DOUT[0:15], PCLK_OUT, HSYNC_OUT, VSYNC_OUT, RX, LOCK, TX, $\overline{PD}$, $\overline{ERROR}$ to GND .....-0.5V to (V_{CCOUT} + 0.5V)
Continuous Power Dissipation (T_A = +70°C)
40-Lead TQFN
Multilayer PCB (derate 35.7mW/°C above +70°C) 2857mW
48-Lead LQFP
Multilayer PCB (derate 21.7mW/°C above +70°C) 1739mW
Junction-to-Case Thermal Resistance (θ_{JC}) (Note 1)
40-Lead TQFN .....1.7°C/W
48-Lead LQFP.....10°C/W
Junction-to-Ambient Thermal Resistance (θ_{JA}) (Note 1)
40-Lead TQFN .....28°C/W
48-Lead LQFP.....46°C/W
ESD Protection
Human Body Model (R_D = 1.5kΩ, C_S = 100pF)
All Pins to GND .....±3kV
IEC 61000-4-2 (R_D = 330Ω, C_S = 150pF)
Contact Discharge
(SDI+, SDI-, SDO+, SDO-) to GND.....±8kV
Air Discharge
(SDI+, SDI-, SDO+, SDO-) to GND.....±20kV
ISO 10605 (R_D = 2kΩ, C_S = 330pF)
Contact Discharge
(SDI+, SDI-, SDO+, SDO-) to GND.....±10kV
Air Discharge
(SDI+, SDI-, SDO+, SDO-) to GND.....±30kV
Machine Model (R_D = 0Ω, C_S = 200pF)
All Pins to GND .....±200V
Storage Temperature Range .....-65°C to +150°C
Junction Temperature.....+150°C
Lead Temperature (soldering, 10s) .....+300°C

Note 1: Package thermal resistances were obtained using the method described in JDEC specification JESD51-7, using a 4-layer board. For detailed information on package thermal considerations, refer to **www.maxim-ic.com/thermal-tutorial**.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

MAX9257 DC ELECTRICAL CHARACTERISTICS

($V_{CC\_}$ = +3.0V to +3.6V, R_L = 50Ω ±1%, T_A = -40°C to +105°C, unless otherwise noted. Typical values are at $V_{CC\_}$ = +3.3V, T_A = +25°C.) (Notes 2, 3)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
SINGLE-ENDED INPUTS

Power-Down to High Impedance	t_{PDD}	(Figure 13)				100	ns
Jitter Tolerance	t_{JT}	Each half of the UI, 12 bit, SRATE = 840Mbps, PRBS pattern (Figure 15)	No spread	0.25	0.30		UI

Note 2: Current into a pin is defined as positive. Current out of a pin is defined as negative. All voltages are referenced to ground except V_{TH} and VTL.

Note 3: Maximum and minimum limits over temperature are guaranteed by design and characterization. Devices are production tested at T_A = +105°C.

Note 4: One output at a time.

Note 5: AC parameters are guaranteed by design and characterization, and are not production tested.

Note 6: C_L includes probe and test jig capacitance.

Note 7: t_T is the period of the PCLK_OUT.

Note 8: For high-speed mode timing, see the *Detailed Description* section.

Note 9: I²C timing parameters are specified for fast-mode I²C. Max data rate = 400kbps.

Typical Operating Characteristics

PIN		NAME	FUNCTION
TQFN	LQFP		
1, 18	2, 21	V_{CCIO}	Single-Ended Input/Output Buffer Supply Voltage. Bypass V_{CCIO} to GND with 0.1µF and 0.001µF capacitors in parallel as close as possible to the device with the smallest value capacitor closest to V_{CCIO}.
2, 11, 19, 34	3, 14, 22, 41	GND	Digital Supply Ground
3–8	4–9	DIN[9:14]/ GPIO[1:6]	Data Input/General Purpose Input/Output. When a serial-data word is less than 18 bits word length, DIN_ not programmed as data inputs becomes GPIO (Table 22). DIN[9:14] are internally pulled down to ground.
9	10	GND_{FPLL}	Filter PLL Ground
10	11	V_{CCFPLL}	Filter PLL Supply Voltage. Bypass V_{CCFPLL} to GND_{FPLL} with 0.1µF and 0.001µF capacitors in parallel as close as possible to the device with the smallest value capacitor closest to V_{CCFPLL}.
12	15	DIN15/GPIO7	Data Input/General Purpose Input/Output. When a serial-data word is less than 18 bits word length, DIN_ not programmed as data input becomes GPIO (Table 22). DIN15 is internally pulled down to ground.
13	16	HSYNC_IN	Horizontal SYNC Input. HSYNC_IN is internally pulled down to ground.
14	17	VSYNC_IN	Vertical SYNC Input. VSYNC_IN is internally pulled down to ground.
15	18	PCLK_IN	Parallel Clock Input. PCLK_IN latches data and sync inputs and provides the PLL reference clock. PCLK_IN is internally pulled down to ground.
16	19	SCL/TX	Open-Drain Control Channel Output. SCL/TX becomes SCL output when UART-to-I²C is active. SCL/TX becomes TX output when UART-to-I²C is bypassed. Externally pull up to V_{CC}.
17	20	SDA/RX	Open-Drain Control Channel Input/Output. SDA/RX becomes bidirectional SDA when UART-to-I²C is active. SDA/RX becomes RX input when UART-to-I²C is bypassed. SDA output requires a pullup to V_{CC}.
20, 33	23, 40	V_{CC}	Digital Supply Voltage. Bypass V_{CC} to ground with 0.1µF and 0.001µF capacitors in parallel as close as possible to the device with the smallest value capacitor closest to V_{CC}.
21	26	GPIO8	General Purpose Input/Output
22	27	GPIO9	General Purpose Input/Output
23	28	V_{CCSPLL}	Spread PLL Supply Voltage. Bypass V_{CCSPLL} to GND_{SPLL} with 0.1µF and 0.001µF capacitors in parallel as close as possible to the device with the smallest value capacitor closest to V_{CCSPLL}.
24	29	GND_{SPLL}	SPLL Ground
25	30	GND_{LVDS}	LVDS Ground
26	31	SDO-	Serial LVDS Inverting Output
27	32	SDO+	Serial LVDS Noninverting Output
28	33	V_{CCLVDS}	LVDS Supply Voltage. Bypass V_{CCLVDS} to GND_{LVDS} with 0.1µF and 0.001µF capacitors in parallel as close as possible to the device with the smallest value capacitor closest to V_{CCLVDS}.

MAX9257 Pin Description (continued)

PIN		NAME	FUNCTION
TQFN	LQFP		
29	34	REM	Remote Power-Up/Power-Down Select Input. Connect REM to ground for power-up to follow V_{CC}. Connect REM high to V_{CC} through 10kΩ resistor for remote power-up. REM is internally pulled down to GND.
30, 31, 32, 35–39	35, 38, 39, 42–46	DIN[0:7]	Data Inputs. DIN[0:7] are internally pulled down to ground.
40	47	DIN8/GPIO0	Data Input/General Purpose Input/Output. When a serial-data word is less than 18 bits word length, DIN_ not programmed as data input becomes GPIO (Table 22). DIN8 is internally pulled down to ground.
—	1, 12, 13 24, 25, 36, 37, 48	N.C.	No Connection. Not internally connected.
—	—	EP	Exposed Pad for Thin QFN Package Only. Connect EP to ground.

MAX9258 Pin Description

PIN	NAME	FUNCTION
1, 12, 13, 24, 25, 36, 37	N.C.	No Connection. Not internally connected.
2	V_{CC}	Digital Supply Voltage. Bypass V_{CC} to GND with 0.1µF and 0.001µF capacitors in parallel as close as possible to the device with the smallest value capacitor closest V_{CC}.
3, 14	GND	Digital Supply Ground
4	$\overline{PD}$	LVCMOS/LVTTL Power-Down Input. Drive $\overline{PD}$ high to power up the device and enable all outputs. Drive $\overline{PD}$ low to put all outputs in high impedance and reduce supply current. $\overline{PD}$ is internally pulled down to ground.
5	V_{CCLVDS}	LVDS Supply Voltage. Bypass V_{CCLVDS} to GND_{LVDS} with 0.1µF and 0.001µF capacitors in parallel as close as possible to the device with the smallest value capacitor closest to V_{CCLVDS}.
6	SDI-	Serial LVDS Inverting Input
7	SDI+	Serial LVDS Noninverting Input
8	GND_{LVDS}	LVDS Supply Ground
9	GND_{PLL}	PLL Supply Ground
10	V_{CCPLL}	PLL Supply Voltage. Bypass V_{CCPLL} to GND_{PLL} with 0.1µF and 0.001µF capacitors in parallel as close to the device as possible with the smallest value capacitor closest to V_{CCPLL}.
11	$\overline{ERROR}$	Active-Low, Open-Drain Error Output. $\overline{ERROR}$ asserts low to indicate a data transfer error was detected (parity, PRBS, or UART control channel error). $\overline{ERROR}$ is high to indicate no error detected. $\overline{ERROR}$ resets when the error registers are read for parity, control channel errors, and when PRBS enable bit is reset for PRBS errors. Pull up to V_{CCOUT} with a 1kΩ resistor.
15	RX	LVCMOS/LVTTL Control Channel UART Output

Fully Programmable Serializer/Deserializer with UART/I²C Control Channel

MAX9258 Pin Description (continued)

PIN	NAME	FUNCTION
16	TX	LVCMOS/LVTTL Control Channel UART Input. TX is internally pulled up to V_{CCOUT}.
17	LOCK	Open-Drain Lock Output. LOCK asserts high to indicate PLLs are locked with correct serial-word boundary alignment. LOCK asserts low to indicate PLLs are not locked or incorrect serial-word boundary alignment was detected. Pull up to V_{CCOUT} with a 1kΩ resistor.
18	PCLK_OUT	LVCMOS/LVTTL Recovered Clock Output
19	VSYNC_OUT	LVCMOS/LVTTL Vertical SYNC Output
20	HSYNC_OUT	LVCMOS/LVTTL Horizontal SYNC Output
21, 28–35, 40–46	DOUT[15:0]	LVCMOS/LVTTL Data Outputs
22, 39	V_{CCOUT}	Output Supply Voltage. V_{CCOUT} is the supply for all output buffers. Bypass V_{CCOUT} to GND_{OUT} with 0.1µF and 0.001µF capacitors in parallel as close as possible to the device with the smallest value capacitor closest to V_{CCOUT}.
23, 38, 48	GND_{OUT}	Output Supply Ground
26	V_{CCSPLL}	Spread-Spectrum PLL Supply Voltage. Bypass V_{CCSPLL} to GND_{SPLL} with 0.1µF and 0.001µF capacitors in parallel as close as possible to the device with the smallest value capacitor closest to V_{CCSPLL}.
27	GND_{SPLL}	SPLL Ground
47	CCEN	LVCMOS/LVTTL Control Channel Enabled Output. CCEN asserts high to indicate that control channel is enabled.

Detailed Description

The MAX9257 serializer pairs with the MAX9258 deserializer to form a complete digital video serial link. The electronic control unit (ECU) programs the registers in the MAX9257, MAX9258, and peripheral devices, such as a camera, during the control channel phase that occurs at startup or during the vertical blanking time. All control channel communication is half-duplex. The UART communication between the MAX9258 and the MAX9257 is encoded to allow transmission through AC-coupling capacitors. The MAX9257 communicates to the peripheral device through UART or I²C.

The MAX9257/MAX9258 DC-balanced serializer and deserializer operate from a 5MHz-to-70MHz parallel clock frequency, and are capable of serializing and deserializing programmable 10, 12, 14, 16, and 18 bits parallel data during the video phase. The MAX9257/MAX9258 have two phases of operation: video and control channel (Figures 19 and 20). During the video phase, the MAX9257 accepts parallel video data and transmits serial encoded data over the LVDS link. The MAX9258 accepts the encoded serial LVDS data and converts it back to parallel output data. The MAX9257 has dedicated inputs for HSYNC and VSYNC. The selected VSYNC edge causes the MAX9257/MAX9258 to enter the control channel phase. Nonactive VSYNC edge can be asserted after eight pixel clock cycles.

The video data are coded using two overhead bits (EN0 and EN1) resulting in a serial-word length of N+2 bits. The MAX9257/MAX9258 feature programmable

parity encoding that adds two parity bits to the serial word. Bit 0 (EN0) is the LSB that is serialized first without parity enabled. The parity bits are serialized first when parity is enabled.

The ECU programs the MAX9258, MAX9257, and peripheral devices at startup and during the control channel phase. In a digital video system, the control channel phase occurs during the vertical blanking time and synchronizes to the VSYNC signal. The programmable active edge of VSYNC initiates the control channel phase. Nonactive edge of VSYNC can transition at any time after 8 x t_T if MAX9257 spread is not enabled and 0.5/f_{SSM} when enabled. At the end of video phase, the MAX9258 drives CCEN high to indicate to the ECU that the control channel is open. Programmable timers and ECU signal activity determine how long the control channel stays open. The timers are reset by ECU signal activity. ECU programming must not exceed the vertical blanking time to avoid loss of video data.

After the control channel phase closes, the MAX9257 sends a 546 or 1090 word pattern as handshaking (HSK) to synchronize the MAX9258's internal clock recovery circuit to the MAX9257's transmitted data. Following the handshaking, the control channel is closed and the video phase begins. The serial LVDS data is recovered and parallel data is valid on the programmed edge of the recovered pixel clock.

Tables 1 and 2 show the default power-up values for the MAX9257/MAX9258 registers. Tables 3 and 4 show the input and output supply references.

Parallel-Word Width

The parallel-word width is made up of the video data bits, HSYNC, and VSYNC. The video data bits are programmable from 8 to 16 depending on the pixel clock, serial-data rate, and parity. Table 16 shows the parallel-word width.

Serial-Word Length

The serial-word length is made up of the parallel-word width, encoding bits, and parity bits. Tables 5–9 show the serial video format and serial-word lengths without parity. Tables 10–13 show with parity bits included.

LVDS Serial Data

Serial LVDS data is transmitted least significant bit (LSB) to most significant bit (MSB) as shown in Tables 5 through 13. The ECU at startup can program the parallel word width, serial frequency range, parity, spread-spectrum, and pixel clock frequency range *(see the MAX9257 Register Table* and the *MAX9258 Register Table).*

Fully Programmable Serializer/Deserializer with UART/I²C Control Channel

Pixel Clock Frequency Range

The MAX9257/MAX9258 each have registers that can be configured at startup. Depending on the word length, the MAX9257 multiplies PCLK_IN (pixel clock) by 12, 14, 16, 18, or 20 using an internal PLL to generate the serial clock. Use Table 20 for proper selection of available PCLK frequency and serial-data ranges. Parallel data is serialized using the serial-clock and serialized bits are transmitted at the MAX9257 LVDS outputs. The MAX9257/MAX9258 support a wide range for PCLK_IN (Table 14). If the pixel clock frequency needs to change to a frequency outside the programmed range, the ECU must program both the MAX9257 and the MAX9258 in the same control channel session.

Serial-Data Rate Range

The word length and pixel clock is limited by the maximum serial-data rate of 840Mbps. The following formula shows the relation between word length, pixel clock, and serial clock:

Serial-word length x pixel clock = serial-data rate ≤ 840Mbps

For example, if PCLK_IN is 70MHz, the serial-word length has to be 12 bits including DC balance bits if parity is not enabled to keep the serial-data rate under 840Mbps. If the serial-word length is 20 bits, the maximum PCLK_IN frequency is 42MHz. The serial-data rate can vary from 60Mbps to 840Mbps and can be programmed at power-up (Table 15). Use Table 20 for proper selection of available PCLK frequency and serial data ranges. Operating in the incorrect range for either the serial-data rate or PCLK_IN can result in excessive current dissipation and failure of the MAX9258 to lock to the MAX9257.

LVDS Common-Mode Bias

The output common-mode bias is 1.2V at the LVDS inputs on the MAX9258 and LVDS outputs on the MAX9257. No external resistors are required to provide bias for AC-coupling the LVDS inputs and outputs.

LVDS Termination

Terminate the LVDS link at both ends with the characteristic impedance of the transmission line (typically 100Ω differential). The LVDS inputs and outputs are high impedance to GND and differentially.

Spread-Spectrum Selection

The MAX9257/MAX9258 each have spread-spectrum options. Both should not be turned on at the same time. When the MAX9257 is programmed for spread spectrum, the MAX9258 tracks and passes the spread to its clock and data outputs. The MAX9257/MAX9258 are both center spread (Figure 21). The control channel does not use spread spectrum, but has slower transition times.

Table 14. MAX9257 Pixel Clock Range (PCLK_IN)

FREQUENCY (MHz)	PRATE (REG0[7:6])
5–10	00
10–20	01
20–40	10
40–70	11

SERIAL-DATA RATE (Mbps)	SRATE (REG0[5:4])
60–100	00
100–200	01
200–400	10
400–840	11

Table 16. Parallel-Word Width

PARALLEL-WORD WIDTH	PWIDTH (REG0[2:0])
10	000
12	001
14	010
16	011
18	1XX

MAX9258 Spread Spectrum

The MAX9258 features a programmable spread-spectrum clock and data outputs for reduced EMI. The single-ended data outputs are programmable for no spread, ±2%, or ±4% (see the *Typical Operating Characteristics*) around the recovered pixel clock frequency. The output spread is programmed in register REG1[7:6]. Table 17 shows the spread options, and Table 18 shows the various modulation rates.

MAX9257 Spread Spectrum

The MAX9257 features programmable spread spectrum for the LVDS outputs. Table 19 shows various spread options, and Table 20 shows the various modulation rates. Only one device (the MAX9257 or the MAX9258) should be programmed for spread spectrum at a time. If the MAX9257 is programmed for spread, the MAX9258

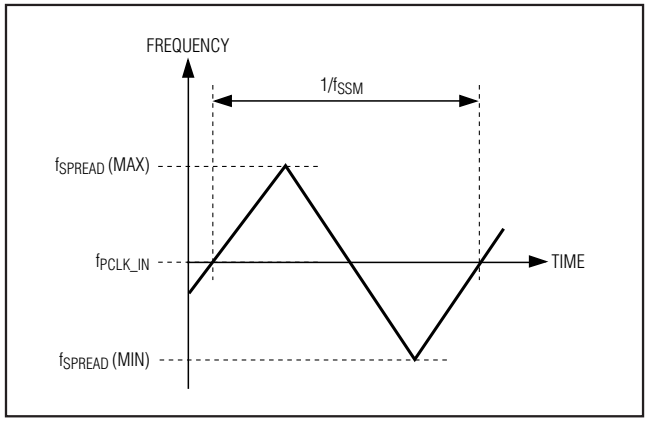

Figure 21. Simplified Modulation Profile for the MAX9257/MAX9258

tracks and passes the spread to the data and clock outputs. The PRATE range of 00 and 01 (5MHz ≤ PCLK ≤ 20MHz) supports all the spread options. The PRATE range of 10 and 11 (20MHz ≤ PCLK ≤ 70MHz) requires that the spread be 2% or less.

Pixel Clock Jitter Filter

The MAX9257 has a PLL to filter high-frequency pixel clock jitter on PCLK_IN. The FPLL can be bypassed by writing 1 to REG4[2]. The FPLL improves the MAX9258's data recovery by filtering out the high-frequency components from the pixel clock that the MAX9258 cannot track. The 3dB bandwidth of the FPLL is 100kHz (typ).

LVDS Output Preemphasis (SDO±)

The MAX9257 features programmable preemphasis where extra current is added when the LVDS outputs transition on the serial link. Preemphasis provides additional current to the normal drive current. For example, 20% preemphasis provides 20% greater current than the normal drive current. Current is boosted only on the transitions and returns to the normal drive current after switching. Select the preemphasis level to optimize the eye diagram. Preemphasis boosts the high-frequency content of the LVDS outputs to enable driving greater cable lengths. The amount of preemphasis is programmed in REG12[7:5] (Table 21).

VSYNC, HSYNC, and Pixel Clock Polarity

PCLK: The MAX9257 is programmable to latch data on either rising or falling edge of PCLK. The polarity of PCLKOUT at the MAX9258 can be independent of the MAX9257 PCLK active edge. The polarity of PCLK can be programmed using REG4[5] of the MAX9257 and the MAX9258.

010	±1.75
011	±2
100	Off
101	±3
110	±3.5
111	±4

VSYNC: The MAX9257 and the MAX9258 enter control channel on the falling edge of VSYNC. The default register settings are VSYNC active falling edge for both the MAX9257 and the MAX9258. If the VSYNC active edge is programmed for rising edge at the MAX9257, the MAX9258 VSYNC active edge must also be programmed for rising edge to reproduce VSYNC rising edge at the MAX9258 output. However, matching the polarity of the VSYNC active edge between the MAX9257 and the MAX9258 is not a requirement for proper operation.

HSYNC: HSYNC active-edge polarity is programmable for the MAX9258.

General Purpose I/Os (GPIOs)

The MAX9257 has up to 10 GPIOs available. GPIO8 and GPIO9 are always available while GPIO[0:7] are available depending on the parallel-word width (Table 22). If GPIOs are not available, the corresponding GPIO bits are not used.

Fully Programmable Serializer/Deserializer with UART/I²C Control Channel

Table 20. MAX9257 Modulation Rate

SERIAL-WORD LENGTH	SRATE	PRATE	PCLK RANGE (MHz)	MODULATION RATE	f_{SSM} RANGE (kHz)
12	11	11	40–70	PCLK/2728	14.7 to 25.7
	11	10	33.3–40	PCLK/1736	19.2 to 23.0
	10	10	20–33.3	PCLK/1612	12.4 to 20.7
	10	01	16.6–20	PCLK/992	16.7 to 20.2
	01	01	10–16.6	PCLK/1116	9.0 to 14.9
	01	00	8.3–10	PCLK/744	11.2 to 13.4
	00	00	5–8.3	PCLK/868	5.8 to 9.6
14	11	11	40–60	PCLK/2304	17.4 to 26.0
	11	10	28.6–40	PCLK/1728	16.6 to 23.1
	10	10	20–28.6	PCLK/1440	13.9 to 19.9
	10	01	14.3–20	PCLK/1008	14.2 to 19.8
	01	01	10–14.3	PCLK/1008	9.9 to 14.2
	01	00	7.1–10	PCLK/720	9.9 to 13.9
	00	00	5–7.1	PCLK/720	6.9 to 9.9
16	11	11	40–52.5	PCLK/1968	20.3 to 26.7
	11	10	25–40	PCLK/1640	15.2 to 24.4
	10	10	20–25	PCLK/1312	15.2 to 19.1
	10	01	12.5–20	PCLK/984	12.7 to 20.3
	01	01	10–12.5	PCLK/820	12.2 to 15.2
	01	00	6.25–10	PCLK/656	9.5 to 15.2
	00	00	5–6.25	PCLK/656	7.6 to 9.5
18	11	11	40–46.6	PCLK/1840	21.7 to 25.3
	11	10	22.2–40	PCLK/1472	15.1 to 27.2
	10	10	20–22.2	PCLK/1104	18.1 to 20.1
	10	01	11.1–20	PCLK/920	12.1 to 21.7
	01	01	10–11.1	PCLK/736	13.6 to 15.1
	01	00	5.6–10	PCLK/736	7.6 to 13.6
	00	00	5–5.6	PCLK/552	9.1 to 10.1
20	11	11	40–42	PCLK/1632	24.5 to 25.7
	11	10	20–40	PCLK/1632	12.3 to 24.5
	10	01	10–20	PCLK/1020	9.8 to 19.6
	01	00	5–10	PCLK/816	6.1 to 12.3

A GPIO can be programmed to drive an LVCMOS logic level or to read a logic input. The register bit that sets the output level when the GPIO is programmed as an output stores the input level when the GPIO is programmed as an input.

Open-Drain Outputs (LOCK, $\overline{ERROR}$)

LOCK and $\overline{ERROR}$ are open-drain outputs that require a pullup resistor to an external supply. $\overline{ERROR}$ asserts low when an error occurs and LOCK is high impedance when the MAX9258 is locked to the MAX9257 and remains high under the locked condition. When the devices are in shutdown, the channel is not locked and LOCK goes high impedance, is pulled high, and should be ignored. $\overline{ERROR}$ is high impedance at shutdown and remains high. In choosing pullup resistors, there is a tradeoff between power dissipation and speed; 10kΩ pullup should be sufficient.

Table 21. Preemphasis

REG12[7:5]	PREEMPHASIS (%)
000,101,110	20
001	40
010	60
011	80
100	100
111	0

Table 22. GPIOs vs. Parallel-Word Width

PARALLEL-WORD WIDTH (N)	GPIOs AVAILABLE
18	GPIO[8:9]
16	GPIO[6:9]
14	GPIO[4:9]
12	GPIO[2:9]
10	GPIO[0:9]

The LOCK and $\overline{\text{ERROR}}$ outputs can be wired in an AND configuration if you have multiple serializers and deserializers, or a single serializer fanned out to multiple deserializers through a repeater. For such situations, wire the multiple LOCK outputs together and use a single pullup resistor to pull up all the lines high. LOCK is high if all the devices are locked. Do the same thing for $\overline{\text{ERROR}}$; $\overline{\text{ERROR}}$ is low if any MAX9258 reports errors.

Base Mode and Bypass Mode (Basics)

In the control channel phase, there are two modes: base and bypass. In base mode, ECU always communicates using the MAX9257/MAX9258 UART protocol and communication with a peripheral device is performed in I²C by the MAX9257. Packets not addressed to the MAX9257 or the MAX9258 get converted to I²C and passed to the peripheral device. Similarly, I²C packets from the peripheral device get converted to UART packets in the reverse direction. ECU can disable communication to the peripheral device by writing a 0 to INTEN (REG8[6] in the MAX9257 and REG7[6] in the MAX9258). Base mode is the default mode. Bypass mode is entered by writing a 0 to INTMODE and 1 to INTEN (Table 23). Bypass mode is exited if there is no activity from ECU in the control channel for the duration of CTO. When CTO times out, INTEN reverts back to 0 and MAX9257/MAX9258 revert back to base mode. To permanently stay in bypass mode, ECU can lock the CTO timer or program CTO to be longer than ETO and STO.

Table 23. Selection of Base Mode or Bypass Mode

INTEN MAX9257 REG8[6], MAX9258 REG7[6]	INTMODE MAX9257 REG8[7], MAX9258 REG7[7]	MODE
0	X	Base mode, communication with peripheral is not enabled
1	1	Base mode, communication with peripheral is enabled (I²C)
1	0	Bypass mode, communication with MAX9257/MAX9258 is not enabled, communication with peripheral is enabled (UART)

Table 24. STO Clock Divide Ratio

0100	16
0101	32
0110	64
0111	128
1000	256
1001	512
1010	1024
1011	2048
1100	4096
1101	8192
1110	16,384
1111	32,768

Timers

The MAX9257/MAX9258 feature three different timers. The start timeout (STO) and end timeout (ETO) control the duration of the control channel. The come-back timeout (CTO) controls the duration of bypass mode.

STO Timer

The STO (start timeout) timer closes the control channel if the ECU does not start using the control channel within the STO timeout period. The STO timer is configured by

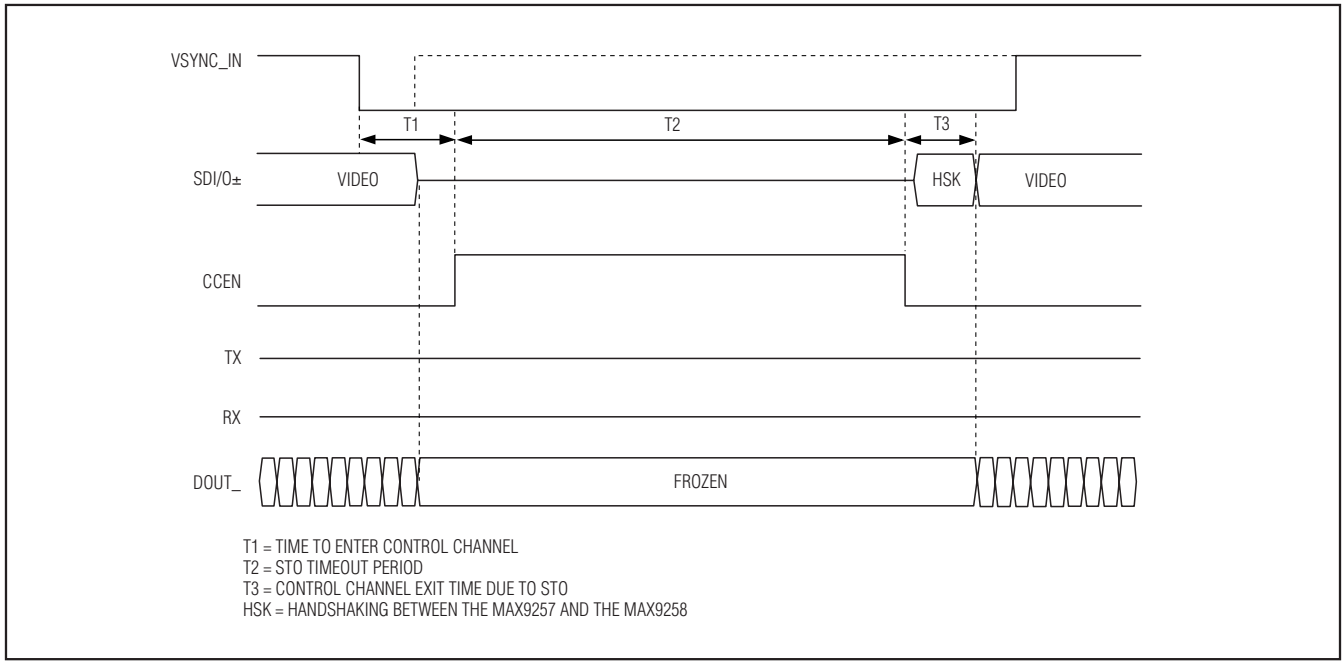

Figure 22. Control Channel Closing Due to STO Timeout

register REG2 for both the MAX9257 and the MAX9258. The four bits of REG2[7:4] select the divide ratio (STODIV) for the STO clock as a function of the pixel clock (Table 24). The timeout period is determined by counter bits REG2[3:0] that increment once every STO clock period. Write to REG2[3:0] to determine the counter end time. The STO counter counts to the programmed STOCNT + 1. The ECU must begin communicating before STO times out, otherwise, the control channel closes (Figure 22). The STO timeout period is given by:

$$t_{STO} = \left(\frac{1}{f_{CLK}}\right) \times STODIV \times (STOCNT + 1)$$

For example:

If the pixel clock frequency is set to 16MHz, STODIV is set to 1010 (STODIV = 1024), and STOCNT is set to 1001 (STOCNT = 9), the STO timer counts with 15.625kHz STO clock (16MHz/1024) internally until it reaches 10 and timer expires. The t_{STO} is equal to t_T x 1024 x 10 = 640µs.

The default value for STODIV is 1024 while the default value for STOCNT is 0. That means the STO timeout period is equal 1024 pixel clock cycles. Activity from the ECU on the control channel shuts off the STO timer and starts the ETO timer.

Table 25. ETO Clock Divide Ratio

REG3[7:4]	ETODIV
00XX	16
0100	16
0101	32
0110	64
0111	128
1000	256
1001	512
1010	1024
1011	2048
1100	4096
1101	8192
1110	16,384
1111	32,768

ETO Timer

The ETO (end timeout) timer closes the control channel if the ECU stops communicating for the ETO timeout period. Configure register REG3[7:4] for both the MAX9257 and the MAX9258 to select the divide ratio (ETODIV) for the ETO clock as a function of the pixel clock (Table 25). The timeout period is determined by

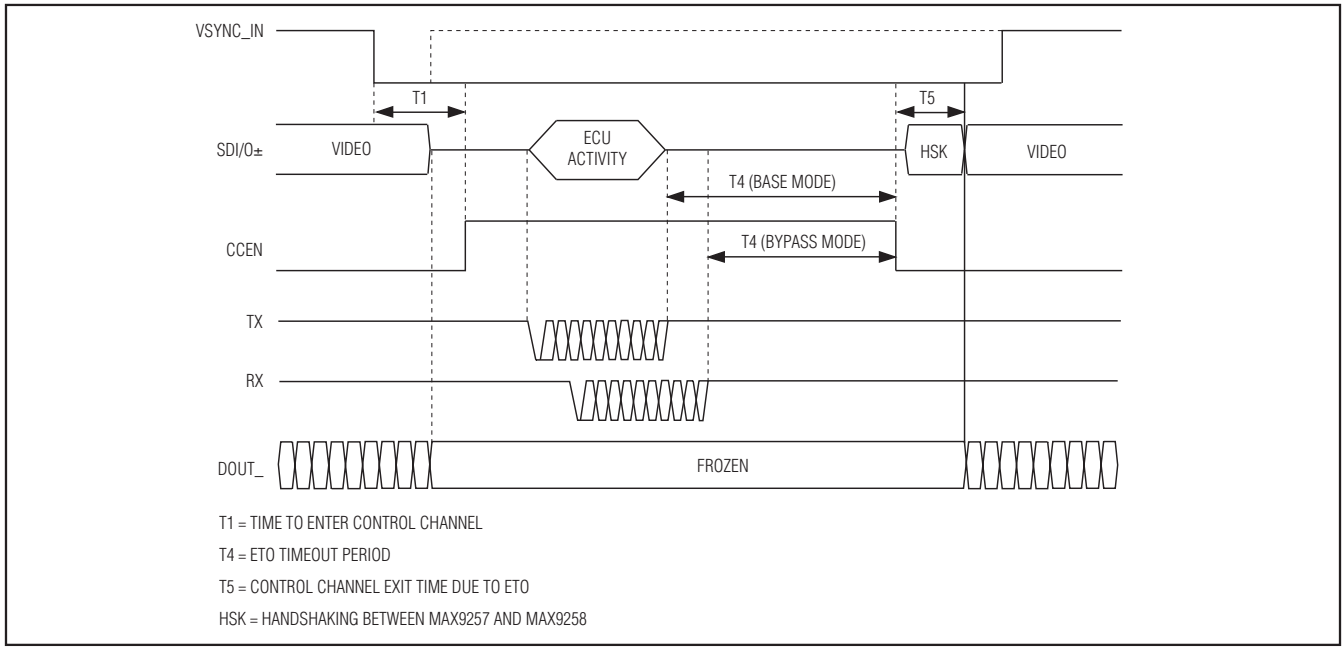

Figure 23. Control Channel Closing Due to ETO Timeout

counter bits REG3[3:0] that increment once every ETO clock period. Write to REG3[3:0] to determine the counter end time. The ETO counter counts to the programmed ETOCNT + 1. Any ECU activity resets the ETO timer. When the ECU stops transmitting data for the ETO timeout period, the control channel closes (Figure 23).

$$t_{ETO} = \left(\frac{1}{f_{CLK}}\right) \times ETODIV \times (ETOCNT + 1)$$

For example:

If the pixel clock frequency is set to 16MHz, ETODIV is set to 1010 (ETODIV = 1024), and ETOCNT is set to 1001 (ETOCNT = 9), the ETO timer counts with the 15.625kHz ETO clock (16MHz/1024) internally until it reaches 10 and timer expires. The t_{ETO} is equal to t_T x 1024 x 10 = 640µs.

The default value for ETODIV is 1024 while the default value for ETOCNT is 0. That means the ETO timeout period is equal to 1,024 pixel clock cycles.

Closing the Control Channel

After the MAX9257 detects the active VSYNC edge, it sends three synchronization words. Once the MAX9258 sees the active VSYNC transition and detects three synchronization words, it enters the control channel phase and CCEN goes high. There is a brief delay of T1 between the VSYNC transition and CCEN transitioning high. The ECU is allowed to communicate when CCEN is high.

If the ECU does not communicate while CCEN is high (Figure 22), the link remains silent and STO starts counting towards its preset timeout counter value. If STO times out (T2), CCEN transitions low and the control channel closes.

If the ECU communicates while CCEN is high and before STO expires (Figure 23), the STO timer is turned off and ETO timer is enabled. The ETO counter (ETOCNT+1) is reset to 0 whenever activity from ECU (base mode) or ECU and Camera (bypass mode) is detected. As long as there is activity from ECU (base mode) or ECU and Camera (bypass mode) on the link, the channel does not close and the ETO counter resets. After the ECU (base mode) or ECU and Camera (bypass mode) ceases link activity, ETO times out (T4), CCEN transitions low, and the control channel closes.

Another way to close the control channel in base mode is for the ECU to send an end frame (EF) to close the control channel without waiting for ETO to time out. Whenever EF is received by both the MAX9257/MAX9258, control channel closes immediately and CCEN goes low. A synchronization frame must precede EF. End frame cannot be used in bypass mode. The control channel must close by EF to report errors back to the ECU.

Fully Programmable Serializer/Deserializer with UART/I²C Control Channel

After the control channel closes, there is a brief handshake period (T3 in Figure 22 and T5 in Figure 23) between the MAX9257 and the MAX9258. The MAX9258 sends a special lock frame to the MAX9257 to indicate if PLL is still locked. The MAX9258 sends the lock frame if the number of decoding errors didn't exceed a threshold in the last LVDS video phase session. The MAX9258 features a proprietary VCO lock that prevents frequency drift while in the control channel for extended periods of time. If MAX9257 receives the lock frame, it understands that the MAX9258 is in a locked state and sends a short training sequence. If the lock frame is not received by the MAX9257, it assumes that the MAX9258 is not locked and sends a long training sequence. After the short or long training sequence is complete, the MAX9257 sends three special synchronization words before entering the video phase. Training sequence is used to resynchronize the MAX9257/MAX9258 before the video phase starts.

The MAX9257/MAX9258 control channel duration is independent of VSYNC. The control channel does not close when VSYNC deasserts, which allows the use of a VSYNC interrupt signal on VSYNC_IN. The control channel must be closed by STO, ETO, or EF. If the control channel does not close before video data becomes available, video data can be lost.

STO/ETO Timer Programming

STO and ETO can be programmed given the values of T2, T4, and maximum values of T1, T3, and T5 (Figures 22, 23):

t_T = pixel clock period, t_{UCLK} = UART period

When spread spectrum is not enabled in MAX9257:

$$\max(T1) = 2.5\mu s + (3 \times t_T) + (4 \times t_{UCLK})$$

When spread spectrum is enabled in MAX9257:

$$\max(T1) = 2.5\mu s + (1400 \times t_T) + (4 \times t_{UCLK})$$

$$T2 = t_{STO}$$

$$T4 = t_{ETO}$$

When pixel clock frequency range (PRATE) is 00 or 01:

$$\max(T3) = \left(\left(\frac{t_{STO}}{8}\right) + 546\right) \times t_T + (20 \times t_{UCLK})$$

$$\max(T5) = \left(\left(\frac{t_{ETO}}{8}\right) + 546\right) \times t_T + (20 \times t_{UCLK})$$

Table 26. CTO Counter Timeout Period

MAX9257 REG2[7:4] MAX9258 REG3[7:4]	COUNTER USING UART BIT TIMES
000	Never come back (lockout)
001	16
010	32
011	48
100	64
101	80
110	96
111	112

When pixel clock frequency range (PRATE) is 10 or 11:

$$\max(T3) = \left(\left(\frac{t_{STO}}{8}\right) + 1090\right) \times t_T + (20 \times t_{UCLK})$$

$$\max(T5) = \left(\left(\frac{t_{ETO}}{8}\right) + 1090\right) \times t_T + (20 \times t_{UCLK})$$

CTO Timer

The CTO (come-back timeout) timer temporarily or permanently blocks programming to the MAX9257/ MAX9258 registers. CTO keeps the MAX9257/ MAX9258 in bypass mode for the CTO timeout period (Table 26). Bypass mode can only be exited when the CTO timer expires. The CTO timer uses the UART bit times for its counter. Note that STO and ETO timers use the pixel clock while CTO uses the UART bit times. The UART period t_{UCLK} synchronizes with the UART bit times, which synchronize every time the SYNC frame is sent.

When the CTO timer times out, INTEN bit in both devices is set to 0 and the MAX9257/MAX9258 revert back to base mode. If communication with the MAX9257/MAX9258 is not needed after initial programming is complete, CTO may be set to 000 (never come back). In this case, CTO never expires and the MAX9257/MAX9258 stay in bypass mode until they are powered down. This prevents accidental programming of the MAX9257/MAX9258 while ECU communicates with the peripheral using a different UART protocol from the MAX9257/MAX9258 UART protocol.

The overall CTO timeout is calculated as follows:

$$t_{CTO} = t_{UCLK} \times CTO$$

Assuming a UART bit rate of 2Mbps, REG2[7:4], REG3[7:4] = 100 (Table 26), CTO = 64, CTO timeout calculated as:

$$t_{CTO} = (0.5\mu s) \times 64 = 32\mu s$$

Link Power-Up

The MAX9258 powers up when the power-down input $\overline{PD}$ goes high. After approximately 130µs, CCEN goes high, indicating the control channel is available. This delay is required because the analog circuitry has to fully wake up. There are two ways to power up the MAX9257. The MAX9257 powers up according to the state of REM. ECU powers up MAX9257 remotely (ECU sends command to power up) when REM is pulled to V_{CC}. The MAX9257 powers up according to the supply voltage when REM is grounded.

Powering the MAX9257 with Serialization Enabled (REM = Ground at Power-Up)

When REM is grounded, the MAX9257 fully powers up when power is applied. The power-down bit PD (REG4[4]) is disabled and serialization bit SEREN (REG4[3]) is enabled. If PCLK_IN is not running, the MAX9257 stays in the control channel. After PCLK_IN is applied, the control channel times out due to STO, ETO, or EF. The MAX9257 starts the handshaking after the MAX9257 locks to PCLK after 32,768 clock cycles. If PCLK_IN is running, serialization starts automatically after PLL of the MAX9257 locks to PCLK_IN with default values in the registers.

Remote Power-Up of the MAX9257 (REM = Pulled Up to V_{CC})

When REM is pulled up to V_{CC}, the MAX9257 wakes up in a low power state, drawing less than 100µA supply current. To wake-up the MAX9257, the ECU first transmits a dummy frame 0xDB and then waits at least 100µs to allow the MAX9257's internal analog circuitry to fully power up. Then the ECU configures the MAX9257 registers, including a write to disable the PD bit (REG4[4]) so that the MAX9257 does not return back to the low power state. Every packet needs to start with a synchronization frame (see the *UART* section). If the PD bit is not disabled within 70ms after transmitting the dummy frame, the MAX9257 returns to the low power state and the whole power-up sequence needs to be repeated. After configuration is complete, the ECU also needs to enable the SEREN bit to start the video phase.

At initial power-up with REM pulled to V_{CC}, default value of SEREN bit is 0, so STO and ETO timers are not active. Control channel is enabled as long as SEREN is 0. This allows the control channel to be used for extensive programming at initial power-up without the channel timing out. UART, parity, framing and packet errors in the control channel communications are reported if end frame is used to close control channel (see the *MAX9258 Error Checking and Reporting* section). For faster identification of errors, verify every write command by reading back the registers before enabling serialization.

Link Power-Down

When the control channel is open, the ECU writes to the PD bit to power down the MAX9257. In this case, to power up the MAX9257 again, the power-up sequence explained in the *Remote Power-Up of the MAX9257 (REM = Pulled Up to V_{CC})* section needs to be repeated. The MAX9258 has a $\overline{PD}$ input that powers down the device.

MAX9258 Error Checking and Reporting

The MAX9258 has an open-drain $\overline{ERROR}$ output. This output indicates various error conditions encountered during the operation of the system. When an error condition is detected and needs to be reported, $\overline{ERROR}$ asserts low. $\overline{ERROR}$ indicates three error conditions: UART, video parity, and PRBS errors.

UART Errors

During control channel communication in base mode, the MAX9257/MAX9258 record UART frame, parity, and packet errors. I²C errors are also recorded by MAX9257 when I²C interface is enabled. If ECU closes the control channel by using end frame (EF), the MAX9257 sends a special internal UART frame back to the MAX9258 called error frame. The MAX9257 UART and I²C errors are reset at the next control channel. The MAX9258 receives the error frame and records the error status in its UART error register (REG13). ECU must use end frame to the close control channel for the MAX9257 to report back UART and I²C errors to the MAX9258. Whenever one of the bits in the UART error register is 1, $\overline{ERROR}$ asserts low. The UART error register is reset when ECU reads it, and $\overline{ERROR}$ deasserts high immediately if UART errors were the only reason that $\overline{ERROR}$ was asserted low. If the MAX9258 is not locked (LOCK = low), UART error is not reported.

Video Parity Errors

When video parity check is enabled (REG0[3] in both devices), the MAX9258 counts the number of video parity errors by checking recovered video words. Value of this counter is reflected in PAERRHI (8 MSB bits, REG11) and PAERRLO (8 LSB bits, REG10). If the number of detected parity errors is greater than or equal to the parity error threshold PATHRHI (REG9) and PATHRLO (REG8), then $\overline{ERROR}$ asserts low. In this

Fully Programmable Serializer/Deserializer with UART/I²C Control Channel

case, $\overline{\text{ERROR}}$ deasserts high after next video phase starts if video parity errors were the only reason that $\overline{\text{ERROR}}$ was asserted low. To report parity errors in bypass mode, program autoerror reset (AER) to 1 (REG1[5] = 1).

Autoerror Reset

The default method to reset errors is to read the respective error registers in the MAX9258 (registers 10, 11, and 13). If errors were present before the next control channel, the error count gets incremented to the previous number. By setting the autoerror reset (AER) bit to 1, the error registers reset when the control channel ends. Setting AER to 1 does not reset PRBS errors.

PRBS Errors

During the PRBS test, the MAX9258 checks received PRBS data words by comparing them to internally generated PRBS data. Detected errors are counted in the PRBS error register (REG12) in the MAX9258. Whenever the number of detected PRBS errors is more than 0, $\overline{\text{ERROR}}$ asserts low. The PRBS error register is reset when ECU writes a 0 to PRBSEN register (REG4[0]). In this case, $\overline{\text{ERROR}}$ deasserts high immediately if PRBS errors were the only reason that $\overline{\text{ERROR}}$ was asserted low.

Short Synchronization Pattern

The short synchronization pattern is part of the handshaking procedure between the MAX9257 and MAX9258 after the control channel phase. It is used to resynchronize the MAX9258's clock and data recovery circuit to the MAX9257 before the video phase begins. The MAX9257 transmits the short synchronization pattern when it receives the lock frame from the MAX9258. The length of short synchronization pattern is dependant on the PRATE range. When PRATE is 00 or 01, the short synchronization pattern consists of 546 words and when PRATE is 10 or 11, the short synchronization pattern consists of 1090 words. Every word is one pixel clock period.

Long Synchronization Pattern

At power-up or when the MAX9257 does not receive a lock frame from the MAX9258, the MAX9257 transmits a long synchronization pattern. The long synchronization pattern consists of 17,410 words. Every word is one pixel clock period. When REM is high, if synchronization is not achieved after 62 attempts, the MAX9257 resets SEREN to 0 so that the control channel stays open to allow troubleshooting. When REM is low, the MAX9257/MAX9258 continuously tries to reestablish the connection.

Table 27. Link Status

LOCK	CCEN	INDICATION
1	0	LVDS channel active
1	1	Control channel active
0	X	PLL loss of lock

Lock Verification (Handshaking)

At the end of every vertical blanking time, the MAX9257 verifies that the MAX9258 did not lose lock. The MAX9258 handshakes with the MAX9257 to indicate lock status. The handshaking occurs after the channel closes (Figures 22 and 23). If the number of decoding errors in a time window did not exceed a certain threshold during the last video phase, the MAX9258 sends back the lock frame that indicates lock. If the MAX9257 receives the lock frame, the MAX9257 transmits a short synchronization pattern. The MAX9258 features a proprietary VCO mechanism that prevents frequency drift while in the control channel. This allows for successful resynchronization after extended use of control channel. If the number of decoding errors in a time window exceeds a certain threshold, the MAX9258 loses lock, LOCK goes low, and the lock frame is not sent. The MAX9258 also loses lock if handshaking is not successful. If the MAX9257 does not receive the lock frame, it transmits a long synchronization pattern before the start of next video phase. When REM = 1, if the lock frame is not received by the MAX9257 after 62 consecutive attempts to synchronize, SEREN is disabled so that the control channel opens permanently for troubleshooting.

Link Status (LOCK and CCEN)

The LOCK output indicates whether the MAX9258 is locked to the MAX9257. LOCK is an open-drain output that needs to be pulled up to V_{CC}. LOCK asserts low to indicate that the MAX9258 is not locked to the MAX9257 and high when it is. In the control channel phase, LOCK stays high if LOCK is high in the video phase. While in the control channel phase, the MAX9258 PLL frequency is held constant, PCLK output is active and data outputs are frozen at their last valid value before entering the control channel. CCEN output indicates whether the MAX9257/MAX9258 are in the control channel phase or video phase. CCEN goes high when the MAX9257/MAX9258 are in the control channel phase (Table 27). Only at initial power-up, CCEN goes high before communication in the control channel is ready (see the *Link Power-Up* section).

Control Channel

Overview of Control Channel Operation

The control channel is used by the ECU to program registers in the MAX9257, MAX9258, and peripheral devices (such as a camera) during vertical blanking, after power-up, or when serialization is disabled. Control channel communication is half-duplex UART. The peripheral interface on the MAX9257 can be programmed to be I²C or UART. Operation of the control channel is synchronized with the VSYNC input after the ECU starts serialization of video data. Programmable timers, ECU signal activity, and end frame determine how long the control channel stays open. The control channel remains open as long as there is signal activity from the ECU. When the control channel closes, the LVDS serial link is reestablished. Once serialization is enabled, the programming of registers (including the control channel overhead time) must be completed within the vertical blanking time to avoid loss of video data. VSYNC can deassert while control channel remains open after eight pixel clock cycles.

The control channel phase begins on the transition of the programmed active edge of VSYNC_IN. In video applications, the VSYNC signal of the peripheral device is connected to VSYNC_IN on the MAX9257. In other applications, a different signal can be used to trigger the control channel phase. When the MAX9257/MAX9258 detect the VSYNC_IN transition, the LVDS video phase disables and the control channel phase is enabled.

The control channel operates in two modes: base and bypass. In base mode, the ECU issues UART commands in a specified format to program the MAX9257/MAX9258 registers. GPIO on the MAX9257 are also programmed in base mode. UART commands are translated to I²C and output to peripheral devices connected to the MAX9257 when not addressed to either the MAX9257 or the MAX9258.

In bypass mode, programming of the MAX9257/MAX9258 registers are temporarily or permanently blocked depending on the programmed value of CTO. Blocking prevents unintentional programming of the MAX9257/MAX9258 registers when the ECU communicates with the peripheral using a UART protocol different than the one specified to program the MAX9257/MAX9258. When the control channel is open, the MAX9258 continues outputting the pixel clock while HSYNC and video data are held at the last value. If spread is enabled on the MAX9258, the pixel clock is spread.

Control Channel Overhead

Control channel overhead consists of lock frame, short synchronization sequence, and error frame. The lock frame is transmitted between the MAX9257 and the MAX9258 without action by the ECU. The error frame is only sent in response to end frame. When MAX9257 spread spectrum is enabled, the control channel is entered after spread reaches center frequency. The overhead from VSYNC falling edge to control channel enable accounts for a maximum of 1400 pixel clock cycles.

Base Mode (Details)

Base mode allows the ECU to communicate with the MAX9257/MAX9258 in UART and a peripheral device in I²C. UART programming of the peripheral device is not possible in base mode. UART packets from the ECU need to follow a certain protocol to program the MAX9257 and the MAX9258 (Figures 28 and 29). Packets not addressed to the MAX9257/MAX9258 get converted to I²C by the MAX9257 and pass to the peripheral device. The MAX9257 receives I²C packets from the peripheral device and converts them to UART packets to send back to the ECU. To disable communication to the peripheral device, write a 0 to INTEN (REG8[6] in the MAX9257 and REG7[6] in the MAX9258).

In base mode, the STO/ETO timers and the EF command are used to control the duration of the control channel. STO and ETO count up and expire when they reach their programmed value. STO and ETO are not enabled at the same time. STO is enabled after CCEN goes high. If there is activity from the ECU before STO times out, STO is disabled and ETO is enabled. The ECU must begin a transaction within an STO timeout or else the channel closes. The ECU can close the channel by allowing ETO to timeout. Activity from the ECU resets the ETO timer. Another way to close the control channel is by sending an end frame (EF). EF closes the channel within 2 to 3 bit times after being received by the MAX9257/MAX9258. The default value of EF is 0xFF, but can be programmed to any other value besides the MAX9257 and the MAX9258 device addresses. The control channel must be closed with EF for control channel errors to be reported.

Program STO to be longer than the time the ECU takes to respond to opening of channel. Program ETO to be longer than the time the ECU pauses between transactions. As long as the ECU performs transactions, ETO is reset and the channel stays open.

The ECU must wait 14 or more bit times before addressing another device during the same control channel session. Failure to wait 14 bit times may result in the packet boundary not being reset. Internal handshaking operations are automatically performed after the channel is closed and before the video phase begins.

Fully Programmable Serializer/Deserializer with UART/I²C Control Channel

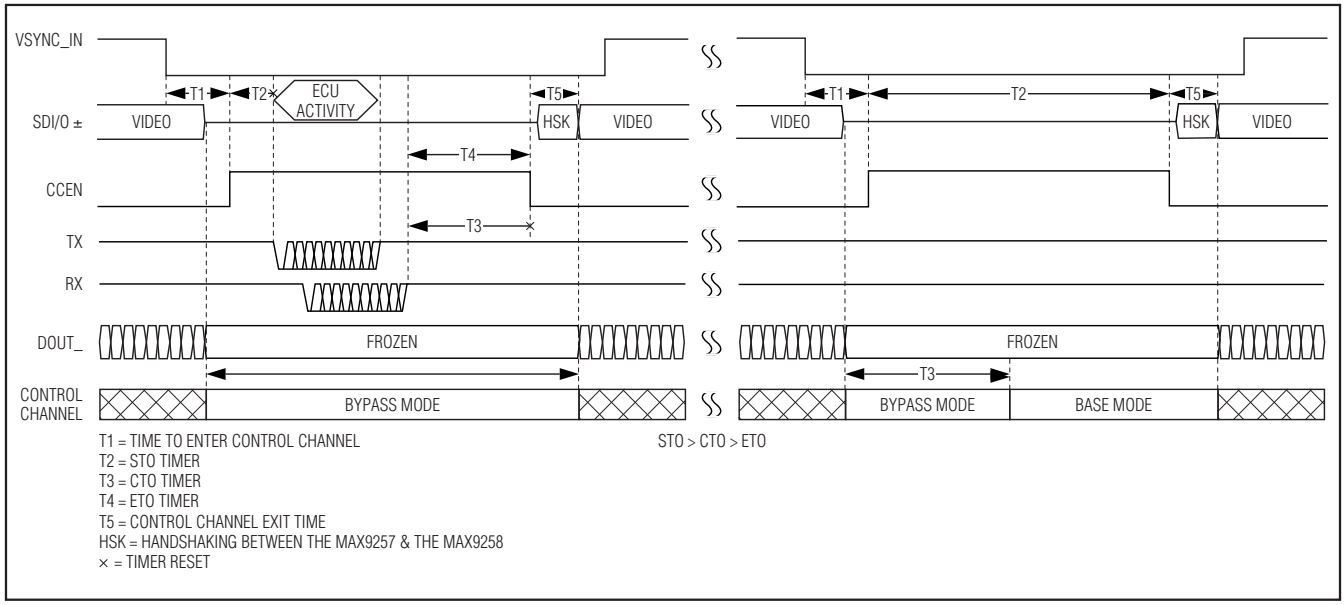

Figure 24. CTO Timing

UART-to-I²C Converter

The UART-to-I²C converter accepts UART read or write packets issued by the ECU and converts them to an I²C master protocol when in base mode. A slave can use an ACK or NACK to indicate a busy or wait state, but cannot hold SCL low to indicate a wait state. Multiple slaves are supported. The UART-to-I²C conversion delay is less than 22 UART bit times and needs to be taken into account when setting the ETO and STO timeout periods for read commands. UART-to-I²C converter converts standard UART format to standard I²C format (Figure 25). This includes data-bit ordering conversion because UART transmits the LSB in first while I²C transmits the MSB first. UART/I²C read delay is a maximum 34 bit times when reading from an I²C peripheral.

The MAX9257/MAX9258 store their own 7-bit device addresses in register REG5. All packets not addressed to the MAX9257/MAX9258 are forwarded to the UART-to-I²C converter. The I²C interfaces (SDA and SCL) are open drain and actively drive a low state. When idle, SDA and SCL are high impedance and pulled high by a pullup resistor. SDA and SCL are idle when packets are addressed to the MAX9257 or MAX9258. SDA and SCL are also idle when the I²C interface is programmed to be disabled.

Bypass Mode (Details)

In bypass mode, ECU activity and UART communication from the camera reset the ETO and CTO timers. This allows the control channel to stay in bypass as long as there is camera activity. In base mode, only ECU activity resets the ETO and CTO timers.

Bypass mode temporarily or permanently blocks programming of the MAX9257/MAX9258. Bypass mode allows only UART programming of peripheral device by ECU. There is no I²C connection in bypass mode. Bypass mode is entered by writing a 0 to INTMODE and by writing a 1 to INTEN (Table 23). Bypass mode disables ECU programming of the MAX9257/MAX9258 to allow any UART communication protocol with the peripheral device. Once bypass mode is entered, the MAX9257/MAX9258 stay in bypass mode until CTO times out.

In bypass mode, the STO and ETO timers determine the control channel duration. CTO timer determines whether to revert back to base mode or not, and EF is not recognized.

A useful setting in bypass mode is to set STO > CTO > ETO because this setting is an alternative to permanent bypass (Figure 24). Use this setting to stay in bypass mode to avoid the overhead of entering from base mode every time the control channel opens. If the ECU uses the channel within a CTO timeout, ETO is activated and then ETO times out before CTO. The channel closes because ETO times out, but channel stays in bypass mode because CTO does not time out. At the next vertical blanking time, bypass mode continues with CTO reset and the ECU can immediately send commands to the camera. If the ECU or camera does not use the channel, CTO times out before STO. STO closes the channel (because ETO is not enabled) if no communication is

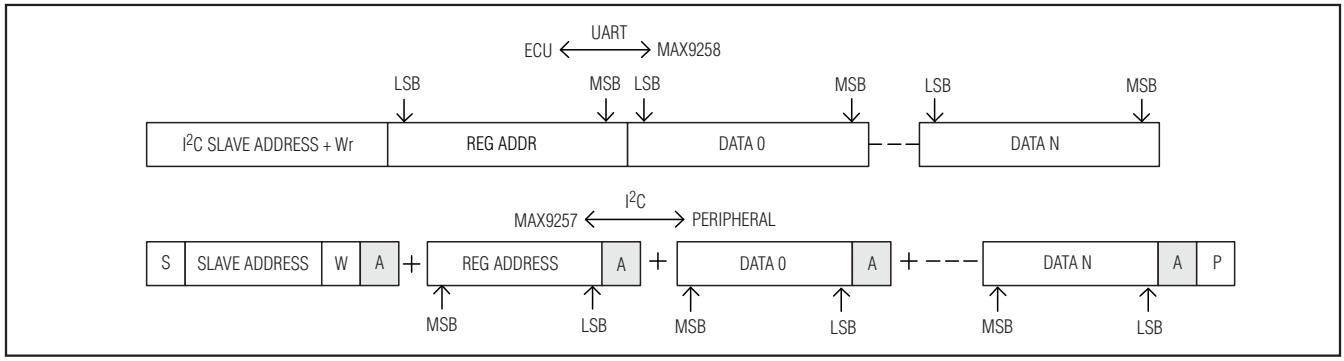

Figure 25. UART-to-I²C Conversion

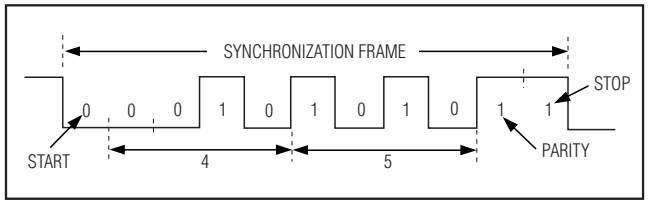

Figure 27. UART Synchronization Frame

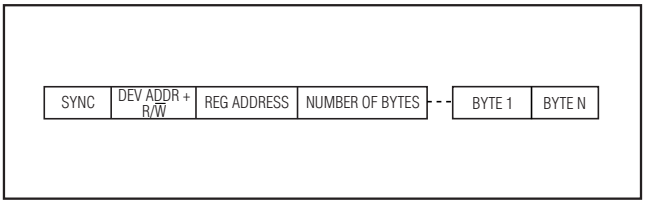

Figure 28. UART Write Packet to MAX9257/MAX9258

sent, but since CTO timed out, bypass mode ends and base mode is active for the next vertical blanking period.

With STO > CTO > ETO, bypass mode can be made continuous by having the ECU send real commands or dummy commands (such as a command to a nonexisting address) each time the control channel opens. Then the ECU does not have to send a command to enter bypass mode each time it wants to program the peripheral device.

UART

UART Frame Format

The UART frame used to program the MAX9257 and the MAX9258 has a low start bit, eight data bits, an even parity bit and a high stop bit. The data following the start bit is the LSB. With even parity, when there are an odd number of 1s in the data bits (D0 through D7) the parity bit is set to 1. The stop bit is sampled and if it is not high, a frame error is generated (Figure 26).

UART Synchronization Frame

The synchronization frame must precede any read or write packets (Figure 26). Transitions in the frame calibrate the oscillators on the MAX9257/MAX9258. The baud rate of the synchronization frame sets the operating baud rate of the control channel. At power-up, UART data rate must be between 95kbps to 400kbps. After power-up, UART data rate can be programmed according to Tables 28 and 29. Data is serialized starting with the LSB first. The synchronization frame is 0x54 as shown in Figure 27.

Write Packet

The ECU writes the sync frame, 7-bit device address plus read/write bit (R/$\overline{W}$ = 0 for write), 8-bit register address, number of bytes to be written, and data bytes (Figure 28). The ECU must follow this UART protocol to correctly program the MAX9257/MAX9258.

Fully Programmable Serializer/Deserializer with UART/I²C Control Channel

Read Packet

The ECU writes the sync frame, 7-bit device address plus read/write bit (R/$\overline{W}$ = 1 for read), 8-bit register address, and number of bytes to be read. The addressed device responds with read data bytes (Figure 29). UART read delay is maximum 4 bit times when reading from the MAX9257 or the MAX9258.

Time Between Frames

Up to two high bit times are allowed between frames.

Reset of Packet Boundary

A high time ranging from 14 UART bit times or more resets the packet boundary. In this case, the next frame received is assumed to belong to a new packet by the MAX9257/MAX9258 and UART-to-I²C converter. Resetting the boundary is required. Not resetting the boundary treats the following packets as part of the first packet, and they may be processed incorrectly.

Data Rate

The control channel data rate in base mode is between 95kbps to 4.25Mbps (Table 28). In bypass mode, the allowed data rate is DC to 10Mbps (Table 29). For data rates faster than 4.25Mbps in bypass mode, REG8[5] in MAX9257 and REG7[5] in MAX9258 must be set high. Set the control channel data rate in base mode by writing to REG8[1:0] in the MAX9257 and REG7[1:0] in the MAX9258. These write commands take effect in the next control channel.

Programming the FAST bit takes effect in the same control channel. Both the MAX9257 and the MAX9258 should have the same settings for FAST. It is recommended to first program the FAST bit in the MAX9257. Programming FAST to 1 results in shorter UART pulses on the differential link.

MAX9257/MAX9258 Device Address Programming

The MAX9257/MAX9258 have device addresses that can be programmed to any 7-bit address. Table 30 shows the default addresses.

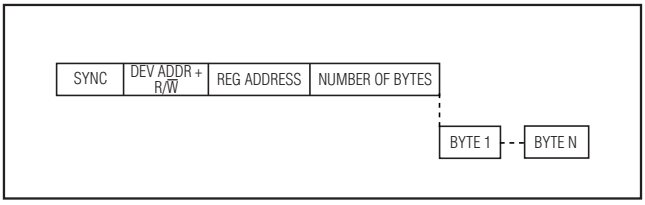

Figure 29. UART Read Packet

MAX9258	1111 1000	0xF8

I²C

The MAX9257 features a UART-to-I²C converter that converts UART packets to I²C. The UART-to-I²C converter works as a repeater between the ECU and external I²C slave devices. The MAX9257 acts as the master and converts UART read/write packets from the ECU to I²C read/write for external I²C slave devices. For writes, the UART-to-I²C converts the UART packets received directly into I²C. For reads, the UART-to-I²C converter follows the UART packet protocol. The I²C SCL clock period is approximately the same as the UART bit clock period (t_{UCLK}). The I²C speed varies with UART speed.

I²C reads from the peripheral device do not disable the ETO timer. Choose ETO large enough so that I²C read commands are not lost due to ETO timing out.

I²C Timing

The MAX9257 acts like a master in I²C communication with the peripheral device. The MAX9257 takes less than 22 UART bit times to convert UART packets into I²C. The SCL and SDA timings are based on the UART bit clock. The I²C data rate is determined by UART and can range from 95kbps to 4.25Mbps. The I²C timing requirements scale linearly from fast mode to higher speeds. Table 31 shows the I²C timing information for data rates greater than 400kbps. The I²C parameters scale with t_{UCLK}. See Figure 30 for timing parameters.

Applications Information

PRBS Test

The MAX9257/MAX9258 have built-in circuits for testing bit errors on the serial link. The MAX9257 has a PRBS generator and the MAX9258 has a PRBS checker. The length of the PRBS pattern is programmable from 2^{21} to 2^{35} word length or continuous by programming REG9[7:4] in the MAX9257. In case of errors, errors are counted in the MAX9258 PRBSERR register (REG12), and the $\overline{ERROR}$ output on the MAX9258 goes low. To start the test, the ECU writes a 1 to PRBSEN bit of both the MAX9257 and the MAX9258. The PRBS test can be

Table 31. Timing Information for I²C Data Rates Greater than 400kbps

PARAMETER	SYMBOL	MIN	TYP	MAX	UNIT
SCL Clock Frequency	f_{SCL}	1	1		t_{UCLK}*

**t_{UCLK} is equal to one UART period.*

Fully Programmable Serializer/Deserializer with UART/I²C Control Channel

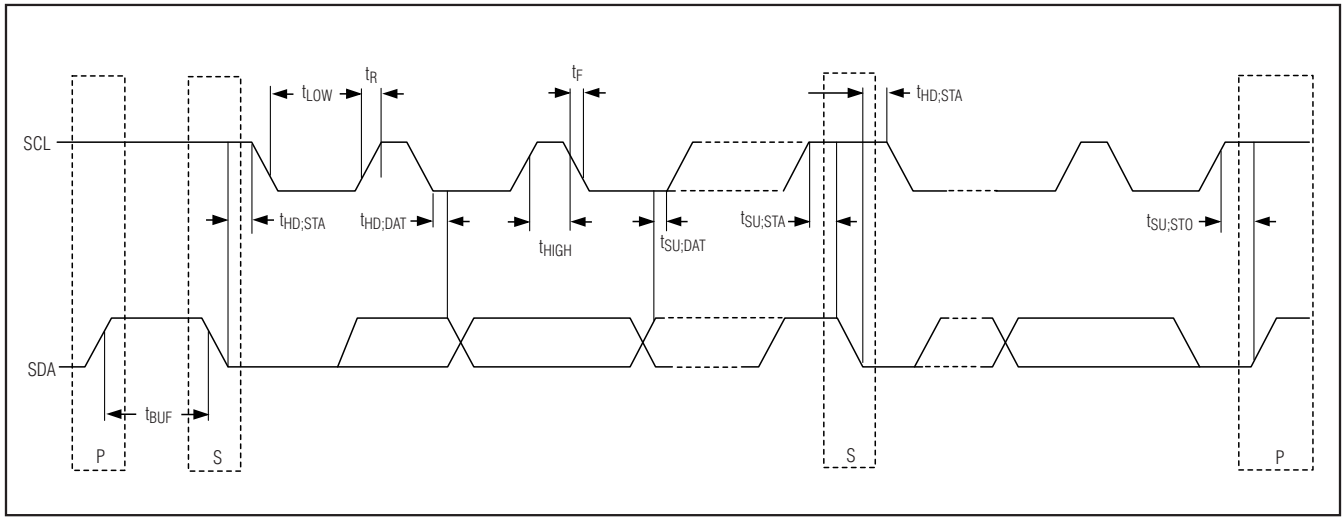

Figure 30. I²C Timing Parameters

performed with or without spread spectrum. If the PRBS test is programmed to run continuously, the MAX9257 must be powered down to stop the test. When programmed for a finite number of repetitions, the control channel is enabled after the PRBS test finishes and serialization enable (SEREN) is reset to 0. To start normal operation, the ECU must disable PRBSEN and enable SEREN.

Video Data Parity

Parity protection of video data is programmable for parallel-word widths of 16 bits or less. When programmed, two parity bits are appended to each parallel word latched into the MAX9257. In the MAX9258, a 16-bit parity error counter logs parity errors. The $\overline{\text{ERROR}}$ output on the MAX9258 goes low if parity errors exceed a programmable threshold.

AC-Coupling Benefits

AC-coupling increases the input voltage of the LVDS receiver to the voltage rating of the capacitor. Two capacitors are sufficient for isolation, but four capacitors—two at the serializer output and two at the deserializer input—provide protection if either end of the cable is shorted to a high voltage. AC-coupling blocks low-frequency ground shifts and common-mode noise.

Selection of AC-Coupling Capacitors

See Figure 31 for calculating the capacitor values for AC-coupling depending on the parallel clock frequency. The plot shows minimum capacitor values for two- and four-capacitor-per-link systems. To block the highest common-mode frequency shift, choose the minimum capacitor value shown in Figure 31. In general, 0.1µF capacitors are sufficient.

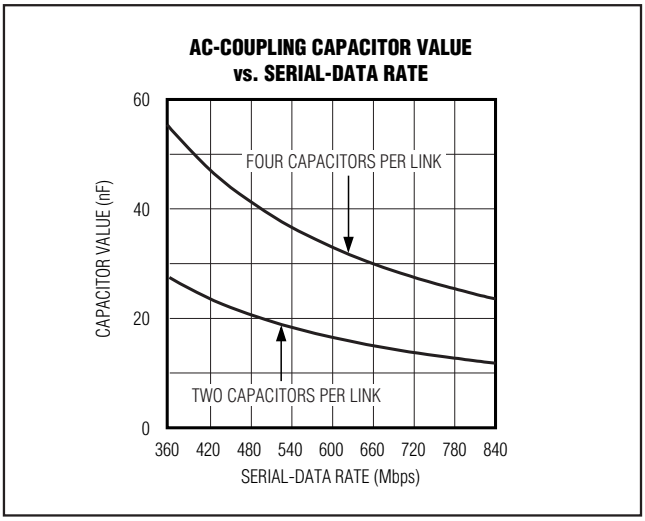

Figure 31. AC-Coupling Capacitor Values vs. Clock Frequency from 18MHz to 42MHz

Optimally Choosing AC-Coupling Capacitors

Voltage droop and the digital sum variaton (DSV) of transmitted symbols cause signal transitions to start from different voltage levels. Because the transition time is finite, starting the signal transition from different voltage levels causes timing jitter. The time constant for an AC-coupled link needs to be chosen to reduce droop and jitter to an acceptable level. The RC network for an AC-coupled link consists of the LVDS receiver termination resistor (R_{TR}),

the LVDS driver termination resistor (R_{TD}), and the series AC-coupling capacitors (C). The RC time constant for four equal-value series capacitors is (C x (R_{TD} + R_{TR}))/4. R_{TD} and R_{TR} are required to match the transmission line impedance (usually 100Ω). This leaves the capacitor selection to change the system time constant. In the following example, the capacitor value for a droop of 2% is calculated:

$$C = -\frac{4 \times t_B \times DSV}{\ln(1 - D) \times (R_{TR} + R_{TD})}$$

where:

C = AC-coupling capacitor (F)

t_B = bit time(s)

DSV = digital sum variation (integer)

ln = natural log

D = droop (% of signal amplitude)

R_{TD} = driver termination resistor (Ω)

R_{TR} = receiver termination resistor (Ω)

The bit time (t_B) is the serial-clock period or the period of the pixel clock divided by the total number of bits. The maximum DSV for the MAX9257 encoding equals to the total number of bits transmitted in one pixel clock cycle. This means that t_B x DSV ≤ t_T.

The capacitor for 2% maximum droop at 16MHz parallel rate clock is:

$$C = -\frac{4 \times t_B \times DSV}{\ln(1 - D) \times (R_{TR} + R_{TD})}$$

Total number of bits is = 10 (data) + 2 (HSYNC and VSYNC) + 2 (encoding) + 2 (parity) = 16

$$C = -\frac{4 \times 3.91ns \times 16}{\ln(1 - .02) \times (100\Omega + 100\Omega)}$$

C ≥ 0.062µF

Jitter due to droop is proportional to the droop and transition time:

$t_J = t_{TT}$ x D

where:

t_J = jitter(s)

t_{TT} = transition time(s) (0 to 100%)

D = droop (% of signal amplitude)

Jitter due to 2% droop and assumed 1ns transition time is:

t_J = 1ns x 0.02

t_J = 20ps

The transition time in a real system depends on the frequency response of the cable driven by the serializer.

The capacitor value decreases for a higher frequency parallel clock and for higher levels of droop and jitter. Use high-frequency, surface-mount ceramic capacitors.

Power-Supply Circuits and Bypassing

All single-ended inputs and outputs on the MAX9257 are powered from V_{CCIO}. All single-ended outputs on the MAX9258 are powered from V_{CCOUT}. V_{CCIO} and V_{CCOUT} can be connected to a +1.71V to +3.6V supply. The input levels or output levels scale with these supply rails.

Board Layout

Separate the LVCMOS/LVTTL signals and LVDS signals to prevent crosstalk. A four-layer PCB with separate layers for power, ground, LVDS, and digital signals is recommended. Layout PCB traces for 100Ω differential characteristic impedance. The trace dimensions depend on the type of trace used (microstrip or stripline). Note that two 50Ω PCB traces do not have 100Ω differential impedance when brought close together—the impedance goes down when the traces are brought closer.

Route the PCB traces for an LVDS channel (there are two conductors per LVDS channel) in parallel to maintain the differential characteristic impedance. Place the 100Ω (typ) termination resistor at both ends of the LVDS driver and receiver. Avoid vias. If vias must be used, use only one pair per LVDS channel and place the via for each line at the same point along the length of the PCB traces. This way, any reflections occur at the same time. Do not make vias into test points for ATE. Make the PCB traces that make up a differential pair the same length to avoid skew within the differential pair.

Cables and Connectors

Interconnect for LVDS typically has a differential impedance of 100Ω. Use cables and connectors that have matched differential impedance to minimize impedance discontinuities. Twisted-pair and shielded twisted-pair cables offer superior signal quality compared to ribbon cable and tend to generate less EMI due to magnetic field canceling effects. Balanced cables pick up noise as common mode that is rejected by the LVDS receiver.

Fully Programmable Serializer/Deserializer with UART/I²C Control Channel

Choosing I²C Pullup Resistors

I²C requires pullup resistors to provide a logic-high level to data and clock lines. There are tradeoffs between power dissipation and speed, and a compromise must be made in choosing pullup resistor values. Every device connected to the bus introduces some capacitance even when device is not in operation. I²C specifies 300ns rise times to go from low to high (30% to 70%) for fast mode, which is defined for a date rate up to 400kbps (see I²C specifications for details). To meet the rise time requirement, choose the pullup resistors so the rise time $t_R = 0.85R_{PULLUP} \times C_{BUS} < 300ns$. If the transition time becomes too slow, the setup and hold times may not be met and waveforms will not be recognized.

	1	0	GPIO1*	General purpose input output 1
	0	0	GPIO0*	General purpose input output 0

MAX9257 Register Table (continued)

ADDRESS	BITS	DEFAULT	NAME	DESCRIPTION
12	7:5	111	PREEMP	LVDS driver preemphasis setting 000 = 20% 111 = off (default) 001 = 40% 101 = 20% 010 = 60% 110 = 20% 011 = 80% 100 = 100%
	4:0	00000		Reserved (set to 00000)
13	7:2	000000		Reserved (set to 000000)
	1:0	00	I²CFILT	I²C glitch filter setting 00 = set according to programmed bit rate (default) 100ns at (95kbps to 400kbps) bit rate 50ns at (400kbps to 1000kbps) bit rate 10ns at (1000kbps to 4250kbps) bit rate 01 = 10ns, 10 = 50ns, 11 = 100ns
14	7:1	(RO)		Reserved
	0	(RO)	LOCKED	PLL locked to pixel clock
15	7:0	(RO)		Reserved

Fully Programmable Serializer/Deserializer with UART/I²C Control Channel

MAX9258 Register Table

ADDRESS	BITS	DEFAULT	NAME	DESCRIPTION
0	7:6	10	PRATE	Pixel clock frequency range 00 = 5MHz to 10MHz 01 = 10MHz to 20MHz 10 = 20MHz to 40MHz (default) 11 = 40MHz to 70MHz
	5:4	11	SRATE	Serial-data rate range 00 = 60Mbps to 100Mbps 01 = 100Mbps to 200Mbps 10 = 200Mbps to 400Mbps 11 = 400Mbps to 840Mbps (default)
	3	0	PAREN	Parity enable 0 = disabled (default), 1 = enabled
	2:0	101	PWIDTH	Parallel data width (includes HSYNC and VSYNC, excludes encoding and parity bits) 000 = 10 100 = 18 001 = 12 101 = 18 (default) 010 = 14 110 = 18 011 = 16 111 = 18
1	7:6	00	SPREAD	Spread-spectrum setting 00 = Off (default) 10 = Off 01 = 2% 11 = 4%
	5	0	AER	Autoerror reset 1 = Reset error count when control channel ends. 0 = Reset upon reading error registers 10, 11, 13 (default)
	4:0	00000		Reserved (set to 000000)
2	Control channel start timeout: (STO) times out if ECU does not start using control channel within this amount of time after control channel session is enabled.			
	7:4	1010	STODIV	Control channel start timeout divider Pixel clock is first divided by : 0000 = 16 1000 = 256 0001 = 16 1001 = 512 0010 = 16 1010 = 1024 (default) 0011 = 16 1011 = 2048 0100 = 16 1100 = 4096 0101 = 32 1101 = 8192 0110 = 64 1110 = 16,384 0111 = 128 1111 = 32,768
	3:0	0000	STOCNT	Control channel start timeout counter Divided pixel clock is used to count up to (STOCNT + 1)

MAX9258 Register Table (continued)

ADDRESS	BITS	DEFAULT	NAME	DESCRIPTION
3	Control channel end timeout: (ETO) times out if ECU does not use control channel for this amount of time after it has already used at least once.			
	7:4	1010	ETODIV	Control channel end timeout divider Pixel clock is first divided by: 0000 = 16 1000 = 256 0001 = 16 1001 = 512 0010 = 16 1010 = 1024 (default) 0011 = 16 1011 = 2048 0100 = 16 1100 = 4096 0101 = 32 1101 = 8192 0110 = 64 1110 = 16,384 0111 = 128 1111 = 32,768
	3:0	0000	ETOCNT	Control channel end timeout counter Divided pixel clock is used to count up to (ETOCNT + 1)
4	7	0	VEDGE	VSYNC active edge at ECU interface 0 = falling (default), 1 = rising
	6	0	HEDGE	HSYNC active edge at ECU interface 0 = falling (default), 1 = rising
	5	1	CKEDGE	PCLK active edge at ECU interface 0 = falling, 1 = rising (default)
	4:1	0000		Reserved (set to 0000)
	0	0	PRBSEN	PRBS test enable 0 = disabled (default), 1 = enabled
5	7:1	1111100	DEVICEID	7-bit address of MAX9258
	0	0		Reserved (set to 0)
6	7:1	1111111	EF	End frame to close control channel
	0	1		Reserved (set to 1)
7	7	0	INTMODE	Interface mode 0 = UART (default), 1 = I²C
	6	0	INTEN	Interface enable 0 = disabled (default), 1 = enabled
	5	0	FAST	Fast UART transceiver 0 = bit rate = DC to 4.25Mbps (default), 1 = bit rate = 4.25Mbps to 10 Mbps
	4:2	000	CTO	Timer to come back from bypass mode (in bit time) 000 = never come back (default) 100 = 64 001 = 16 101 = 80 010 = 32 110 = 96 011 = 48 111 = 112
	1:0	00	BITRATE	Control channel bit rate range in base mode 00 = 95kbps to 400kbps (default) 01 = 400kbps to 1000kbps 10 = 1000kbps to 4250kbps 11 = 1000kbps to 4250kbps

MAX9258 Register Table (continued)

ADDRESS	BITS	DEFAULT	NAME	DESCRIPTION
8	7:0	00010000	PATHRLO	Threshold for number of video parity errors (8 LSBs) If the number of errors exceeds this value, ERR pin is asserted.
9	7:0	00000000	PATHRHI	Threshold for number of video parity errors (8 MSBs) If the number of errors exceeds this value, ERR pin is asserted.
10	7:0	(RO)	PAERRLO	Number of video parity errors (8 LSBs)
11	7:0	(RO)	PAERRHI	Number of video parity errors (8 MSBs)
12	7:0	(RO)	PRBSERR	PRBS test number of bit errors Automatically reset when PRBS test is disabled 0xFF indicates 255 or more errors
13	7:5	(RO)		Reserved
	4	(RO)	DESPERR	Parity error during communication with deserializer
	3	(RO)	DESFERR	Frame error during communication with deserializer
	2	(RO)	SERPERR	Parity error during communication with serializer
	1	(RO)	SERFERR	Frame error during communication with serializer
	0	(RO)	I²CERR	Error during communication with camera in I²C mode
14	7:0	(RO)		Reserved

ESD Protection

The MAX9257/MAX9258 ESD tolerance is rated for Human Body Model, Machine Model, IEC 61000-4-2 and ISO 10605. The ISO 10605 and IEC 61000-4-2 standards specify ESD tolerance for electronic systems. LVDS outputs on the MAX9257 and LVDS inputs on the MAX9258 meet ISO 10605 ESD protection and IEC 61000-4-2 ESD protection. All other pins meet the Human Body Model and Machine Model ESD tolerances. The Human Body Model discharge components are C_S = 100pF and R_D = 1.5kΩ (Figure 33). The IEC 61000-4-2 discharge components are C_S = 150pF and R_D = 330Ω (Figure 32). The ISO 10605 discharge components are C_S = 330pF and R_D = 2kΩ (Figure 34). The Machine Model discharge components are C_S = 200pF and R_D = 0Ω (Figure 35).
