General Description

The Supertex HT01 8-channel level translator is designed to implement necessary level translation between logic level signals and voltage swings required to drive high-voltage P-channel MOSFET transistors. This device is intended to provide gate drive signals to devices such as the Supertex AP01 P-channel MOSFET array in applications requiring active pull-up to a high-voltage (V_{PP}) line of up to 300 volts. Logic input can be from 5 volts to 15 volts and is referenced to the logic supply (V_{DD}).

When an input is switched to 4.2 volts below the V_{DD} supply, the corresponding output will typically switch from V_{PP} to $V_{PP} - 14$ volts. If the V_{PP} supply remains above 12 volts, the negative supply (V_{NN}) would be connected to system ground (GND). If variations of the V_{PP} supply level require the P-channel MOSFET gate drive to swing below GND in order to turn on, connect the V_{NN} pin to a negative supply of up to -15 volts. The logic inputs can remain between V_{DD} and system ground (GND) and still provide correct operation.

In an OFF condition, the HT01 is a low power device. In an ON condition, each channel will dissipate power determined by the V_{PP} and V_{NN} voltage. Internal power dissipation must be considered when the application requires that more than one channel be active at one time, especially at higher V_{PP} voltage values.
