Cautions 1. Connect directly the Internally Connected (IC) pin to Vss.

2. The AVDD pin functions as both an A/D converter power supply and a port power supply. When the μ PD78056F and 78058F are used in applications where the noise generated inside the microcontroller needs to be reduced, connect the AVDD pin to another power supply which has the same potential as VDD.
3. The AVss pin functions as both an A/D and D/A converter ground and as a port ground. When the μ PD78056F and 78058F are used in applications where the noise generated inside the microcontroller needs to be reduced, connect the AVss pin to a ground line other than Vss.

1. The AVDD pin functions as both an A/D converter power supply and a port power supply. When the μ PD78056F and 78058F are used in applications where the noise generated inside the microcontroller needs to be reduced, connect the AVDD pin to another power supply which has the same potential as VDD.
 2. The AVss pin functions as both an A/D converter and D/A converter ground and as a port ground. When the μ PD78056F and 78058F are used in applications where the noise generated inside the microcontroller needs to be reduced, connect the AVss pin to a ground line other than Vss.

5.9 Real-Time Output Port Functions

Data set previously in the real-time output buffer register is transferred to the output latch by hardware concurrently with timer interrupt request and external interrupt request generation in order to output to off-chip. This is a real-time output function. Pins to output to off-chip are called real-time output ports.

By using a real-time output port, a signal which has no jitter can be output. This is most applicable to control of stepping motors, etc.

7. EXTERNAL DEVICE EXPANSION FUNCTIONS

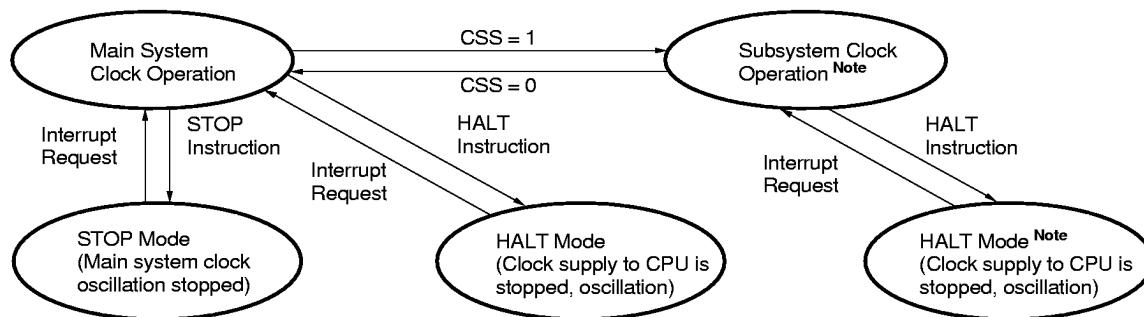

The external device expansion functions connect external devices to areas other than the internal ROM, RAM and SFR. Ports 4 to 6 are used for external device connection.

8. STANDBY FUNCTION

There are the following two standby functions to reduce the system power consumption.

- HALT mode : The CPU operating clock is stopped.
The average consumption current can be reduced by intermittent operation in combination with the normal operating mode.
- STOP mode : The main system clock oscillation is stopped. The whole operation by the main system clock is stopped, so that the system operates with ultra-low power consumption using only the subsystem clock.

Figure 8-1. Stand-by Function

Note The power consumption can be reduced by stopping the main system clock. When the CPU is operating on the subsystem clock, set bit 7 (MCC) in the processor clock control register (PCC) to stop the main system clock. The STOP instruction cannot be used.

Caution When the main system clock is stopped and the system is operated by the subsystem clock, the subsystem clock should be switched again to the main system clock after the oscillation stabilization time is secured by the program.

Remark CSS : bit 4 in the PCC

9. RESET FUNCTION

There are the following two reset methods.

- External reset input by RESET pin
- Internal reset by watchdog time runaway time detection

Remark Unless specified otherwise, alternate-function pin characteristics are the same as port pin characteristics.

Main System Clock Oscillation Circuit Characteristics ($T_A = -40$ to 85°C , $V_{DD} = 2.7$ to 6.0 V)

External clock		X1 input frequency (f_x) Note 1		1.0		5.0	MHz
		X1 input high/low level width (t_{xH} , t_{xL})		85		500	ns

Notes 1. Indicates only oscillation circuit characteristics. Refer to "AC Characteristics" for instruction execution time.

2. Time required to stabilize oscillation after reset or STOP mode release.

Cautions 1. When using the main system clock oscillator, wiring in the area enclosed with the broken line in the above figures should be carried out as follows to avoid an adverse effect from wiring capacitance.

- Wiring should be as short as possible.
- Wiring should not cross other signal lines.
- Wiring should not be placed close to a varying high current.
- The potential of the oscillator capacitor ground should be the same as V_{SS} .
- Do not ground wiring to a ground pattern in which a high current flows.
- Do not fetch a signal from the oscillator.

2. When the main system clock is stopped and the system is operated by the subsystem clock, the subsystem clock should be switched again to the main system clock after the oscillation stabilization time is secured by the program.

Subsystem Clock Oscillation Circuit Characteristics ($T_A = -40$ to $+85^\circ\text{C}$, $V_{DD} = 2.7$ to 6.0 V)

External clock		XT1 input frequency (f_{XT}) Note 1		32		100	kHz
		XT1 input high-/low-level width (t_{XTH} , t_{XTL})		5		15	μ s

Notes 1. Indicates only oscillation circuit characteristics. Refer to "AC Characteristics" for instruction execution time.
 2. Time required to stabilize oscillation after V_{DD} reaches oscillator voltage MIN.

Cautions 1. When using the subsystem clock oscillator, wiring in the area enclosed with the broken line in the above figures should be carried out as follows to avoid an adverse effect from wiring capacitance.

- Wiring should be as short as possible.
- Wiring should not cross other signal lines.
- Wiring should not be placed close to a varying high current.
- The potential of the oscillator capacitor ground should be the same as V_{SS} .
- Do not ground wiring to a ground pattern in which a high current flows.
- Do not fetch a signal from the oscillator.

2. The subsystem clock oscillator is a low-amplitude circuit in order to achieve a low consumption current, and is more prone to malfunction due to noise than the main system clock oscillator. Particular care is therefore required with the wiring method when the subsystem clock is used.

Note When the pull-up resistor is not included in P60 to P63 (specified by a mask option), a -200 μA (MAX.) low-level input leakage current flows only at the 1.5 clock interval (no wait) when the read instruction to port 6 (PM6) and port mode register (PM6) is executed. At times other than this 1.5 interval, a -3 μA (MAX.) current flows.

Remark The characteristics of alternate-function pins and port pins are the same unless specified otherwise.
