

NM25C020

2048-Bit Serial CMOS EEPROM

(Serial Peripheral Interface (SPI™) Synchronous Bus)

General Description

The NM25C020 is a 2048-bit CMOS EEPROM with a SPI compatible serial interface. The NM25C020 is designed for data storage in applications requiring both nonvolatile memory and in-system data updates. This EEPROM is well suited for applications using the 68HC11 series of microcontrollers that support the SPI interface for high speed communication with peripheral devices via a serial bus to reduce pin count. The NM25C020 is implemented in National Semiconductor's floating gate CMOS process that provides superior endurance and data retention.

The serial data transmission of this device requires four signal lines to control the device operation: Chip Select (CS), Clock (SCK), Serial Data In (SI), and Serial Data Out (SO). All programming cycles are completely self-timed and do not require an erase before WRITE.

BLOCK WRITE protection is provided by programming the STATUS REGISTER with one of four levels of write protection. Additionally, separate write enable and write disable instructions are provided for data protection.

Hardware data protection is provided by the $\overline{WP}$ pin to protect against accidental data changes. The HOLD pin allows

the serial communication to be suspended without resetting the serial sequence.

Features

- 2.1 MHz clock rate
- 2048-bits organized as 256 x 8
- Multiple chips on the same 3-wire bus with separate chip select lines
- Self-timed programming cycle
- Simultaneous programming of 1 to 4 bytes at a time
- Status register can be polled during programming to monitor READY/BUSY
- Write Protect ($\overline{WP}$) pin and write disable instruction for both hardware and software write protection
- Block write protect feature to protect against accidental writes
- Endurance: 10^6 data changes
- Data retention greater than 40 years
- Packages available: 8-Pin DIP, 8-Pin SO or 8-Pin TSSOP

Output Load	$C_L = 200$ pF
Input Pulse Levels	$0.1 * V_{CC} - 0.9 * V_{CC}$
Timing Measurement Reference Level	$0.3 * V_{CC} - 0.7 * V_{CC}$

Note 1: Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of the specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Note 2: The SCK frequency specification specifies a minimum clock period of 476 ns; therefore, in a SCK clock cycle, $t_{CLH} + t_{CLL}$ must be ≥ 476 ns. For example, if $t_{CLL} = 190$ ns, then the minimum $t_{CLH} = 286$ ns in order to meet the SCK frequency specification.

Note 3: $\overline{CS}$ must be brought high for a minimum of 240 ns (t_{CSH}) between consecutive instruction cycles.

Low Voltage $2.7V \leq V_{CC} \leq 5.5V$ Specifications

Absolute Maximum Ratings (Note 1)

Note 3: $\overline{CS}$ must be brought high for a minimum of 240 ns (t_{CSH}) between consecutive instruction cycles.

FIGURE 1. Synchronous Data Timing Diagram

TL/D/12400-3

FIGURE 2. SPI Serial Interface

Note: When connected to the SPI port of a 68HC11 microcontroller, the NM25C020 accepts a clock phase of 0 and a clock parity of 0.

Functional Description

MASTER: The device that generates the serial clock is designated as the master. The NM25C020 can never function as a master.

SLAVE: The NM25C020 always operates as a slave as the serial clock pin is always an input.

TRANSMITTER/RECEIVER: The NM25C020 has separate pins for data transmission (SO) and reception (SI).

MSB: The Most Significant Bit is the first bit transmitted and received.

CHIP SELECT: The chip is selected when pin $\overline{CS}$ is low. When the chip is not selected, data will not be accepted from pin SI, and the output pin SO is in high impedance.

SERIAL OP-CODE: The first byte transmitted after the chip is selected with $\overline{CS}$ going low contains the op-code that defines the operation to be performed.

PROTOCOL: When connected to the SPI port of a 68HC11 microcontroller, the NM25C020 accepts a clock phase of 0 and a clock polarity of 0. The SPI protocol for this device defines the byte transmitted on the SI and SO data lines for proper chip operation. See Figure 3.

HOLD: The HOLD pin is used in conjunction with the $\overline{CS}$ to select the device. Once the device is selected and a serial sequence is underway, HOLD may be forced low to suspend further serial communication with the device without resetting the serial sequences. Note that HOLD must be brought low while the SCK pin is low. The device must remain selected during this sequence. To resume serial communication HOLD is brought high while the SCK pin is low. Pins SI, SCK and SO are at a high impedance state during HOLD. See Figure 4.

FIGURE 3. SPI Protocol

FIGURE 4. HOLD Timing

Functional Description (Continued)

TABLE I

Instruction Name	Instruction Format	Operation
WREN	00000110	Set Write Enable Latch
WRDI	00000100	Reset Write Enable Latch
RDSR	00000101	Read Status Register
WRSR	00000001	Write Status Register
READ	00000011	Read Data from Memory Array
WRITE	00000010	Write Data to Memory Array

INVALID OP-CODE: After an invalid code is received, no data is shifted into the NM25C020, and the SO data output pin remains high impedance until a new CS falling edge re-initializes the serial communication. See Figure 5.

FIGURE 5. Invalid Op-Code

TL/D/12400-7

READ SEQUENCE (One or More Bytes): Reading the memory via the SPI link requires the following sequence. The CS line is pulled low to select the device. The READ op-code is transmitted on the SI line followed by the byte address (A7-A0) to be read. After this is done, data on the SI line becomes don't care. The data (D7-D0) at the address specified is then shifted out on the SO line. If only one byte is to be read, the CS line can be pulled back to the high level. It is possible to continue the READ sequence as the byte

FIGURE 6. Read Sequence

TL/D/12400-8

FIGURE 7. Read Status

TL/D/12400-9

address is automatically incremented and data will continue to be shifted out. When the highest address is reached (FF), the address counter rolls over to lowest address (000) allowing the entire memory to be read in one continuous READ cycle. See Figure 6.

READ STATUS REGISTER (RDSR): The Read Status Register (RDSR) instruction provides access to the status register which is used to interrogate the READY/BUSY and WRITE ENABLE status of the chip. Two nonvolatile status register bits are used to select one of four levels of BLOCK WRITE PROTECTION. The status register format is shown in Table II.

TABLE II. Status Register Format

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
1	1	1	1	BP1	BP0	WEN	RDY

Status register Bit 0 = 0 (RDY) indicates that the device is READY; Bit 0 = 1 indicates that a program cycle is in progress. Bit 1 = 0 (WEN) indicates that the device is not WRITE ENABLED. Bit 1 = 1 indicates that the device is WRITE ENABLED. Non-volatile status register Bits 2 and 3 (BP0 and BP1) indicate the level of BLOCK WRITE PROTECTION selected. The block write protection levels and corresponding status register control bits are shown in Table III. Note that if a RDSR instruction is executed during a programming cycle only the RDY bit is valid. All other bits are 1s. See Figure 7.

TABLE III. Block Write Protection Levels

Level	Status Register Bits		Array Addresses Protected
	BP1	BP0	
0	0	0	None
1	0	1	C0-FF
2	1	0	80-FF
3	1	1	00-FF

Functional Description (Continued)

WRITE ENABLE (WREN): When V_{CC} is applied to the chip, it "powers up" in the write disable state. Therefore, all programming modes must be preceded by a WRITE ENABLE (WREN) instruction. Additionally the $\overline{WP}$ pin must be held high during a WRITE ENABLE instruction. At the completion of a WRITE or WRSR cycle the device is automatically returned to the write disable state. Note that a WRITE DISABLE (WRDI) instruction or forcing the $\overline{WP}$ pin low will also return the device to the write disable state. See Figure 8.

FIGURE 8. Write Enable

WRITE DISABLE (WRDI): To protect against accidental data disturbance the WRITE DISABLE (WRDI) instruction disables all programming modes. See Figure 9.

FIGURE 9. Write Disable

WRITE SEQUENCE: To program the device the WRITE PROTECT ($\overline{WP}$) pin must be held high and two separate instructions must be executed. The chip must first be write enabled via the WRITE ENABLE instruction and then a WRITE instruction must be executed. Moreover, the address of the memory location(s) to be programmed must be outside the protected address field selected by the Block Write Protection Level. See Table III.

A WRITE command requires the following sequence. The $\overline{CS}$ line is pulled low to select the device, then the WRITE op-code is transmitted on the SI line followed by the byte address (A7-A0) and the corresponding data (D7-D0) to be written. Programming will start after the $\overline{CS}$ pin is forced back to a high level. Note that the LOW to HIGH transition of the $\overline{CS}$ pin must occur during the SCK low time immediately after clocking in the D0 data bit. See Figure 10.

The READY/BUSY status of the device can be determined by executing a READ STATUS REGISTER (RDSR) instruction. Bit 0 = 1 indicates that the WRITE cycle is still in progress and Bit 0 = 0 indicates that the WRITE cycle has ended. During the WRITE programming cycle (Bit 0 = 1) only the READ STATUS REGISTER instruction is enabled.

The NM25C020 is capable of a 4 byte PAGE WRITE operation. After receipt of each byte of data the two low order address bits are internally incremented by one. The seven high order bits of the address will remain constant. If the master should transmit more than 4 bytes of data, the address counter will "roll over", and the previously loaded data will be reloaded.

At the completion of a WRITE cycle the device is automatically returned to the write disable state.

If the $\overline{WP}$ pin is forced low or the device is not WRITE enabled, the device will ignore the WRITE instruction and return to the standby state when $\overline{CS}$ is forced high. A new $\overline{CS}$ falling edge is required to re-initialize the serial communication. See Figure 11.

FIGURE 10. Write Sequence

FIGURE 11. Start Write Condition

Functional Description (Continued)

WRITE STATUS REGISTER (WRSR): The WRITE STATUS REGISTER (WRSR) instruction is used to program the non-volatile status register Bits 2 and 3 (BP0 and BP1). The WRITE PROTECT (WP) pin must be held high and two separate instructions must be executed. The chip must first be write enabled via the WRITE ENABLE instruction and then a WRSR instruction must be executed.

The WRSR command requires the following sequence. The $\overline{CS}$ line is pulled low to select the device and then the WRSR op-code is transmitted on the SI line followed by the data to be programmed. See Figure 12.

Note that the first four bits are don't care bits followed by BP1 and BP0 then two additional don't care bits. Programming will start after the $\overline{CS}$ pin is forced back to a high level. As in the WRITE instruction the LOW to HIGH transition of the $\overline{CS}$ pin must occur during the SCK low time immediately after clocking the last don't care bit. See Figure 13.

The READY/BUSY status of the device can be determined by executing a READ STATUS REGISTER (RDSR) instruction. Bit 0 = 1 indicates that the WRSR cycle is still in progress and Bit 0 = 0 indicates that the WRSR cycle has ended.

At the completion of a WRSR cycle the device is automatically returned to the write disable state.

FIGURE 13. Start WRSR Condition

TL/D/12400-15

Functional Description (Continued)**Mode 2: Master Reset****Sequence of Operation**

1. Input and Output Ready, HF and FULL can be in any state before the reset sequence with Master Reset ($\overline{MR}$) HIGH.
2. Master Reset goes LOW and clears the FIFO, setting up all essential internal states. Master Reset must be LOW pulse width t_{MRW} before rising again.
3. Master Reset rises.

4. IR rises (if not HIGH already) to indicate ready to write state recovery time t_{MRRH} after the falling edge of $\overline{MR}$. Both HF and FULL will go LOW indicating an empty FIFO, occurring recovery times t_{MRE} and t_{MRO} respectively after the falling edge of $\overline{MR}$. OR falls recovery time t_{MRORL} after $\overline{MR}$ falls. Data at outputs goes LOW recovery time t_{MRONL} after $\overline{MR}$ goes LOW.
5. Shift-In can be taken HIGH after a minimum recovery time t_{MRSIH} after $\overline{MR}$ goes HIGH.

FIGURE 2. Mode of Operation Mode 2

TL/F/10144-6

Functional Description (Continued)**Mode 3: With FIFO Full, Shift-In is Held HIGH In Anticipation of an Empty Location****Sequence of Operation**

1. The FIFO is initially full and Shift-In goes HIGH. OR is initially HIGH. Shift-Out is LOW. IR is LOW.
2. Shift-Out is pulsed HIGH, Shift-Out pulse propagates and the first data word is latched on the rising edge of SO. OR falls on this edge. On the falling edge of SO, the second data word appears after propagation delay t_D . New data is written into the FIFO after SO goes LOW.
3. Input Ready goes HIGH one fall-through time, t_{FT} , after the falling edge of SO. Also, HF goes HIGH one t_{OF} after SO falls, indicating that the FIFO is no longer full.
4. IR returns LOW pulse width t_P after rising and shifting new data in. Also, HF returns LOW pulse width t_{3F} after rising, indicating the FIFO is once more full.
5. Shift-In is brought LOW to complete the shift-in process and maintain normal operation

TL/F/10144-7

Note: MR and FULL are HIGH; OE is LOW.

FIGURE 3. Modes of Operation Mode 3

Functional Description (Continued)**Mode 4: Shift-Out Sequence, FIFO Full to Empty****Sequence of Operation**

1. FIFO is initially full and OR is HIGH, indicating valid data is at the output. IR is LOW.
2. SO goes HIGH, resulting in OR going LOW one propagation delay, t_{OR} , after SO rises. OR LOW indicates output stage is busy.
3. SO goes LOW, new data reaches output one propagation delay, t_D , after SO falls; OR goes HIGH one propagation delay, t_{OR} , after SO falls and HF rises one propagation delay, t_{OF} , after SO falls. IR rises one fall-through time, t_{FT} , after SO falls.
4. Repeat process through the 64th SO pulse. FULL flag goes LOW one propagation delay, t_{OHF} , after the rising edge of 33rd SO, indicating that the FIFO is less than half full. On the falling edge of the 64th SO, HF goes LOW one propagation delay, t_{OE} , after SO, indicating the FIFO is empty. The SO pulse may rise and fall again with an attempt to unload an empty FIFO. This results in no change in the data on the outputs as the 64th word stays latched.

Note: SI and $\overline{OE}$ are LOW; $\overline{MR}$ is HIGH; D_0-D_8 are immaterial.

FIGURE 4. Modes of Operation Mode 4

TL/F/10144-8

Functional Description (Continued)

Mode 5: With FIFO Empty, Shift-Out is Held HIGH In Anticipation of Data

Sequence of Operation

- 1. FIFO is initially empty; Shift-Out goes HIGH.
- 2. Shift-In pulse loads data into the FIFO and IR falls. HF rises propagation delay t_{x1} after the falling edge of SI.
- 3. OR rises a fall-through time of t_{FTO} after the falling edge of Shift-In, indicating that new data is ready to be output.
- 4. Data arrives at output one propagation delay, t_{OD5} , after the falling edge of Shift-In.
- 5. OR goes LOW pulse width t_{OP} after rising and HF goes LOW pulse width t_{x3} after rising, indicating that the FIFO is empty once more.
- 6. Shift-Out goes LOW, necessary to complete the Shift-Out process.

TL/F/10144-9

Note: FULL is LOW; IR is HIGH; OE is LOW; $t_{OPF} = t_{FTO} - t_{OD5}$. Data output transition—valid data arrives at output stage t_{OPF} after OR is HIGH.

FIGURE 5. Modes of Operation Mode 5
