

512Kx8 Nonvolatile SRAM

Features

- Data retention in the absence of power
- Automatic write-protection during power-up/power-down cycles
- Industry-standard 32-pin 512K x 8 pinout
- Conventional SRAM operation; unlimited write cycles
- 10-year minimum data retention in absence of power
- Battery internally isolated until power is applied
- Industrial temperature operation

General Description

The CMOS bq4015 is a nonvolatile 4,194,304-bit static RAM organized as 524,288 words by 8 bits. The integral control circuitry and lithium energy source provide reliable nonvolatility coupled with the unlimited write cycles of standard SRAM.

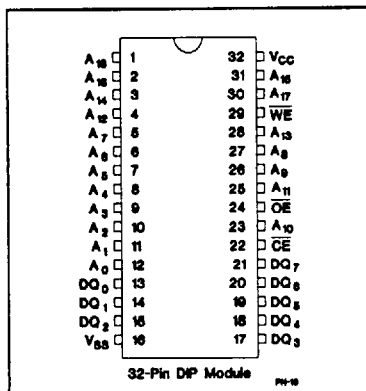

The control circuitry constantly monitors the single 5V supply for an out-of-tolerance condition. When VCC falls out of tolerance, the SRAM is unconditionally write-protected to prevent an inadvertent write operation.

At this time the integral energy source is switched on to sustain the memory until after VCC returns valid.

The bq4015 uses extremely low standby current CMOS SRAMs, coupled with small lithium coin cells to provide nonvolatility without long write-cycle times and the write-cycle limitations associated with EEPROM.

The bq4015 requires no external circuitry and is compatible with the industry-standard 4Mb SRAM pinout.

Functional Description

When power is valid, the bq4015 operates as a standard CMOS SRAM. During power-down and power-up cycles, the bq4015 acts as a nonvolatile memory, automatically protecting and preserving the memory contents.

Power-down/power-up control circuitry constantly monitors the VCC supply for a power-fail-detect threshold V_{PPD}. The bq4015 monitors for V_{PPD} = 4.62V typical for use in systems with 5% supply tolerance. The bq4015Y monitors for V_{PPD} = 4.37V typical for use in systems with 10% supply tolerance.

When VCC falls below the V_{PPD} threshold, the SRAM automatically write-protects the data. All outputs become high impedance, and all inputs are treated as "don't care." If a valid access is in process at the time of power-fail detection, the memory cycle continues to completion. If the memory cycle fails to terminate within time t_{WPT}, write-protection takes place.

As VCC falls past V_{PPD} and approaches 3V, the control circuitry switches to the internal lithium backup supply, which provides data retention until valid VCC is applied.

When VCC returns to a level above the internal backup cell voltage, the supply is switched back to VCC. After VCC ramps above the V_{PPD} threshold, write-protection continues for a time t_{CER} (120ms maximum) to allow for processor stabilization. Normal memory operation may resume after this time.

The internal coin cells used by the bq4015 have an extremely long shelf life and provide data retention for more than 10 years in the absence of system power.

As shipped from Benchmarq, the integral lithium cells are electrically isolated from the memory. (Self-discharge in this condition is approximately 0.5% per year.) Following the first application of VCC, this isolation is broken, and the lithium backup provides data retention on subsequent power-downs.

Notes:

- $\overline{\text{WE}}$ is held high for a read cycle.
- Device is continuously selected: $\overline{\text{CE}} = \overline{\text{OE}} = \text{VIL}$.
- Address is valid prior to or coincident with $\overline{\text{CE}}$ transition low.
- $\overline{\text{OE}} = \text{VIL}$.

t _{OW}	Output active from end of write	5	-	0	-	0	-	ns	I/O pins are in output state. (5)

- Notes:**
1. A write ends at the earlier transition of \overline{CE} going high and \overline{WE} going high.
 2. A write occurs during the overlap of a low \overline{CE} and a low \overline{WE} . A write begins at the later transition of \overline{CE} going low and \overline{WE} going low.
 3. Either t_{WR1} or t_{WR2} must be met.
 4. Either t_{DH1} or t_{DH2} must be met.
 5. If \overline{CE} goes low simultaneously with \overline{WE} going low or after \overline{WE} going low, the outputs remain in high-impedance state.

Write Cycle No. 2 ($\overline{\text{CE}}$ -Controlled) ^{1,2,3,4,5}

WC-4

- Notes:
1. $\overline{\text{CE}}$ or $\overline{\text{WE}}$ must be high during address transition.
 2. Because I/O may be active ($\overline{\text{OE}}$ low) during this period, data input signals of opposite polarity to the outputs must not be applied.
 3. If $\overline{\text{OE}}$ is high, the I/O pins remain in a state of high impedance.
 4. Either t_{WR1} or t_{WR2} must be met.
 5. Either t_{DH1} or t_{DH2} must be met.

Power-Down/Power-Up Cycle ($T_A = T_{OPR}$)

Symbol	Parameter	Minimum	Typical	Maximum	Unit	Conditions
t_{PF}	VCC slew, 4.75 to 4.25 V	300	-	-	μs	
t_{FS}	VCC slew, 4.25 to V_{SO}	10	-	-	μs	
t_{PU}	VCC slew, V_{SO} to V_{PFD} (max.)	0	-	-	μs	
t_{CER}	Chip enable recovery time	40	80	120	ms	Time during which SRAM is write-protected after VCC passes V_{PFD} on power-up.
t_{DR}	Data-retention time in absence of VCC	10	-	-	years	$T_A = 25^\circ C$. (2)
t_{WPT}	Write-protect time	40	100	150	μs	Delay after VCC slews down past V_{PFD} before SRAM is write-protected.

Note:

1. Typical values indicate operation at $T_A = 25^\circ C$, $V_{CC} = 5V$.
2. Batteries are disconnected from circuit until after VCC is applied for the first time. t_{DR} is the accumulated time in absence of power beginning when power is first applied to the device.

Caution: Negative undershoots below the absolute maximum rating of -0.3V in battery-backup mode may affect data integrity.
