

S29CD-J & S29CL-J Flash Family
S29CD032J, S29CD016J, S29CL032J, S29CL016J
32/16 Megabit CMOS 2.6 Volt or 3.3 Volt-only
Simultaneous Read/Write, Dual Boot, Burst Mode
Flash Memory with Versatile/O™

Data Sheet

PRELIMINARY

Notice to Readers: This document indicates states the current technical specifications regarding the Spansion product(s) described herein. The Preliminary status of this document indicates that a product qualification has been completed, and that initial production has begun. Due to the phases of the manufacturing process that require maintaining efficiency and quality, this document may be revised by subsequent versions or modifications due to changes in technical specifications.

Notice On Data Sheet Designations

Spansion issues data sheets with Advance Information or Preliminary designations to advise readers of product information or intended specifications throughout the product life cycle, including development, qualification, initial production, and full production. In all cases, however, readers are encouraged to verify that they have the latest information before finalizing their design. The following descriptions of Spansion data sheet designations are presented here to highlight their presence and definitions.

Advance Information

The Advance Information designation indicates that Spansion is developing one or more specific products, but has not committed any design to production. Information presented in a document with this designation is likely to change, and in some cases, development on the product may discontinue. Spansion therefore places the following conditions upon Advance Information content:

"This document contains information on one or more products under development at Spansion Inc. The information is intended to help you evaluate this product. Do not design in this product without contacting the factory. Spansion Inc. reserves the right to change or discontinue work on this proposed product without notice."

Preliminary

The Preliminary designation indicates that the product development has progressed such that a commitment to production has taken place. This designation covers several aspects of the product life cycle, including product qualification, initial production, and the subsequent phases in the manufacturing process that occur before full production is achieved. Changes to the technical specifications presented in a Preliminary document should be expected while keeping these aspects of production under consideration. Spansion places the following conditions upon Preliminary content:

"This document states the current technical specifications regarding the Spansion product(s) described herein. The Preliminary status of this document indicates that product qualification has been completed, and that initial production has begun. Due to the phases of the manufacturing process that require maintaining efficiency and quality, this document may be revised by subsequent versions or modifications due to changes in technical specifications."

Combination

Some data sheets will contain a combination of products with different designations (Advance Information, Preliminary, or Full Production). This type of document will distinguish these products and their designations wherever necessary, typically on the first page, the ordering information page, and pages with DC Characteristics table and AC Erase and Program table (in the table notes). The disclaimer on the first page refers the reader to the notice on this page.

Full Production (No Designation on Document)

When a product has been in production for a period of time such that no changes or only nominal changes are expected, the Preliminary designation is removed from the data sheet. Nominal changes may include those affecting the number of ordering part numbers available, such as the addition or deletion of a speed option, temperature range, package type, or V_{IO} range. Changes may also include those needed to clarify a description or to correct a typographical error or incorrect specification. Spansion applies the following conditions to documents in this category:

"This document states the current technical specifications regarding the Spansion product(s) described herein. Spansion Inc. deems the products to have been in sufficient production volume such that subsequent versions of this document are not expected to change. However, typographical or specification corrections, or modifications to the valid combinations offered may occur."

Questions regarding these document designations may be directed to your local sales office.

S29CD-J & S29CL-J Flash Family

S29CD032J, S29CD016J, S29CL032J, S29CL016J

32/16 Megabit CMOS 2.6 Volt or 3.3 Volt-only

Simultaneous Read/Write, Dual Boot, Burst Mode

Flash Memory with VersatileI/O™

Data Sheet

PRELIMINARY

General Description

The Spansion S29CD-J and S29CL-J devices are Floating Gate products fabricated in 110-nm process technology. These burst-mode Flash devices are capable of performing simultaneous read and write operations with zero latency on two separate banks, using separate data and address pins. These products can operate up to 75 MHz (32 Mb) or 66 MHz (16 Mb), and use a single V_{CC} of 2.5V to 2.75V (S29CD-J) or 3.0V to 3.6V (S29CL-J) that make them ideal for today's demanding automotive applications.

Distinctive Characteristics

- Single 2.6 V (S29CD-J) or 3.3 V (S29CL-J) for read/program/erase
- 110 nm Floating Gate Technology
- Simultaneous Read/Write operation with zero latency
- x32 Data Bus
- Dual Boot Sector Configuration (top and bottom)
- Flexible Sector Architecture
 - CD016J & CL016J: Eight 2K Double word, Thirty-two 16K Double word, and Eight 2K Double Word sectors
 - CD032J & CL032J: Eight 2K Double word, Sixty-two 16K Double Word, and Eight 2K Double Word sectors
- VersatileI/O™ control (1.65V to 3.6V)
- Programmable Burst Interface
 - Linear for 2, 4, and 8 double word burst with or without wrap around
- Secured Silicon Sector that can be either factory or customer locked
- 20 year data retention (typical)
- Cycling Endurance: 1 million write cycles per sector (typical)
- Command set compatible with JEDEC (JC42.4) standard
- Supports Common Flash Interface (CFI)
- Extended Temperature range
- Persistent and Password methods of Advanced Sector Protection
- Unlock Bypass program command to reduce programming time
- ACC input pin to reduce factory programming time
- Data Polling bits indicate program and erase operation completion
- Hardware (WP#) protection of two outermost sectors in the large bank
- Ready/Busy (RY/BY#) output indicates data available to system
- Suspend and Resume commands for Program and Erase Operation
- Offered Packages
 - 80-pin PQFP
 - 80-ball Fortified BGA
 - Pb-free package option available
 - Known Good Die

Performance Characteristics

| Read Access Times | | | | |
|--|----------------|----|----|----|
| Speed Option (MHz) | 75 (32Mb only) | 66 | 56 | 40 |
| Max Asynch. Access Time, ns (t_{ACC}) | 48 | 54 | 54 | 54 |
| Max Synch. Burst Access, ns (t_{BACC}) | 7.5 (FBGA) | 8 | 8 | 8 |
| Min Initial Clock Delay (clock cycles) | 5 | 4 | 4 | 3 |
| Max CE# Access Time, ns (t_{CE}) | 52 | 54 | 54 | 54 |
| Max OE# Access time, ns (t_{OE}) | 20 | 20 | 20 | 20 |

| Current Consumption (Max values) | |
|----------------------------------|------------|
| Continuous Burst Read @ 75MHz | 90 mA |
| Program | 50 mA |
| Erase | 50 mA |
| Standby Mode | 60 μ A |

| Typical Program and Erase Times | |
|---------------------------------|------------|
| Double Word Programming | 18 μ s |
| Sector Erase | 1.0 s |

2 Input/Output Descriptions and Logic Symbols

Table identifies the input and output package connections provided on the device.

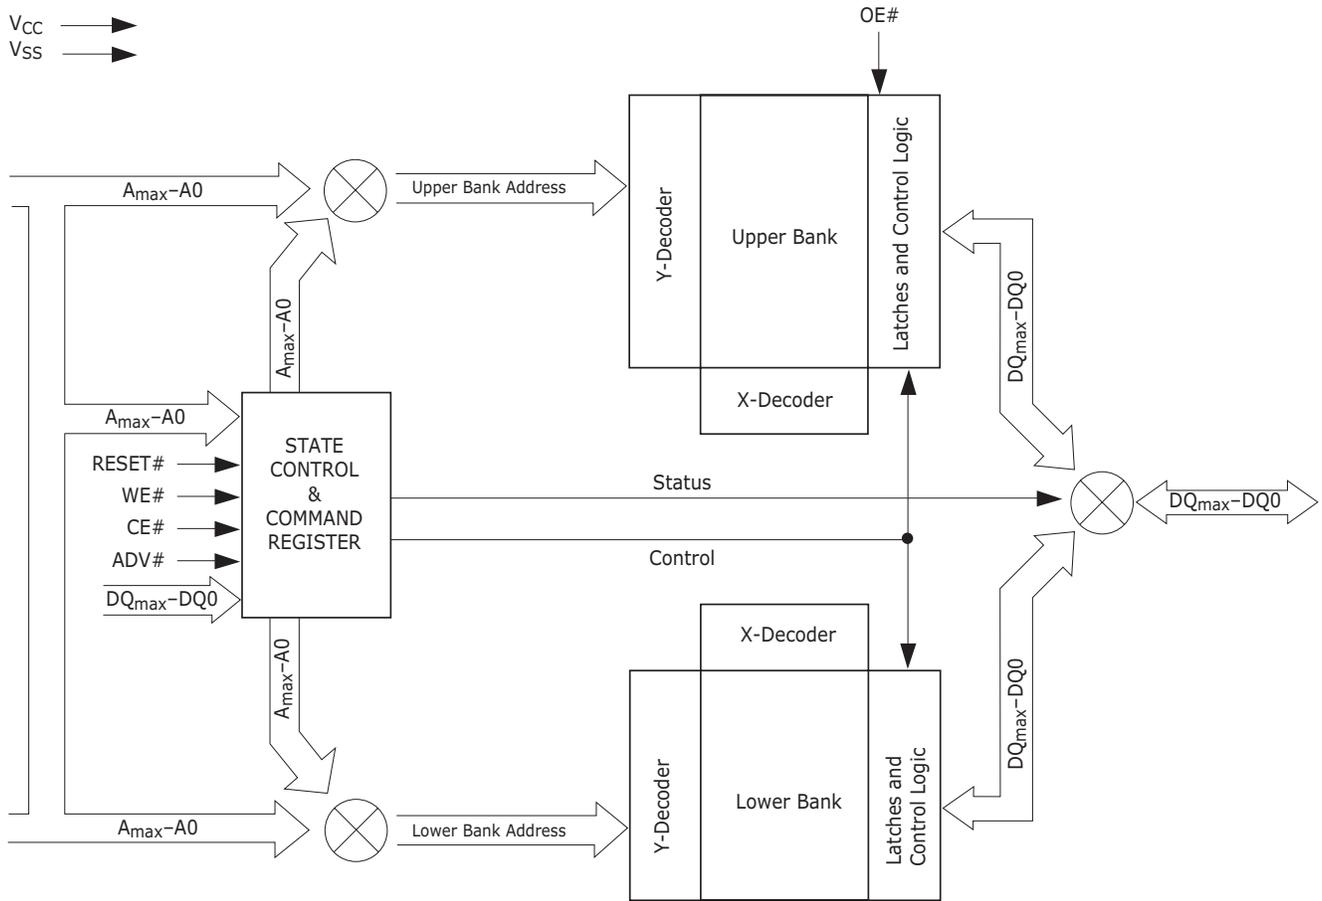

| Symbol | Type | Description |
|----------|------------|---|
| A19-A0 | Input | Address lines for S29CD-J and S29CL-J (A18-A0 for 16Mb and A19-A0 for 32Mb). A9 supports 12V autoselect input. |
| DQ31-DQ0 | I/O | Data input/output |
| CE# | Input | Chip Enable. This signal is asynchronous relative to CLK for the burst mode. |
| OE# | Input | Output Enable. This signal is asynchronous relative to CLK for the burst mode. |
| WE# | Input | Write Enable |
| VCC | Supply | Device Power Supply. This signal is asynchronous relative to CLK for the burst mode. |
| VIO | Input | VersatileI/O™ Input. |
| VSS | I/O | Ground |
| NC | No Connect | Not connected internally |
| RY/BY# | Output | Ready/Busy output and open drain which require a external pull up resistor. When RY/BY# = V_{OH} , the device is ready to accept read operations and commands. When RY/BY# = V_{OL} , the device is either executing an embedded algorithm or the device is executing a hardware reset operation. |
| CLK | Input | Clock Input that can be tied to the system or microprocessor clock and provides the fundamental timing and internal operating frequency. |
| AVD # | Input | Load Burst Address input. Indicates that the valid address is present on the address inputs. |
| IND# | Output | End of burst indicator for finite bursts only. IND is low when the last word in the burst sequence is at the data outputs. |
| WAIT# | Output | Provides data valid feedback only when the burst length is set to continuous. |
| WP# | Input | Write Protect Input. At V_{IL} , disables program and erase functions in two outermost sectors of the large bank. |
| ACC | Input | Acceleration input. At V_{HH} , accelerates erasing and programming. When not used for acceleration, ACC = V_{SS} to V_{CC} . |
| RESET# | Input | Hardware Reset. |

3 Block Diagram

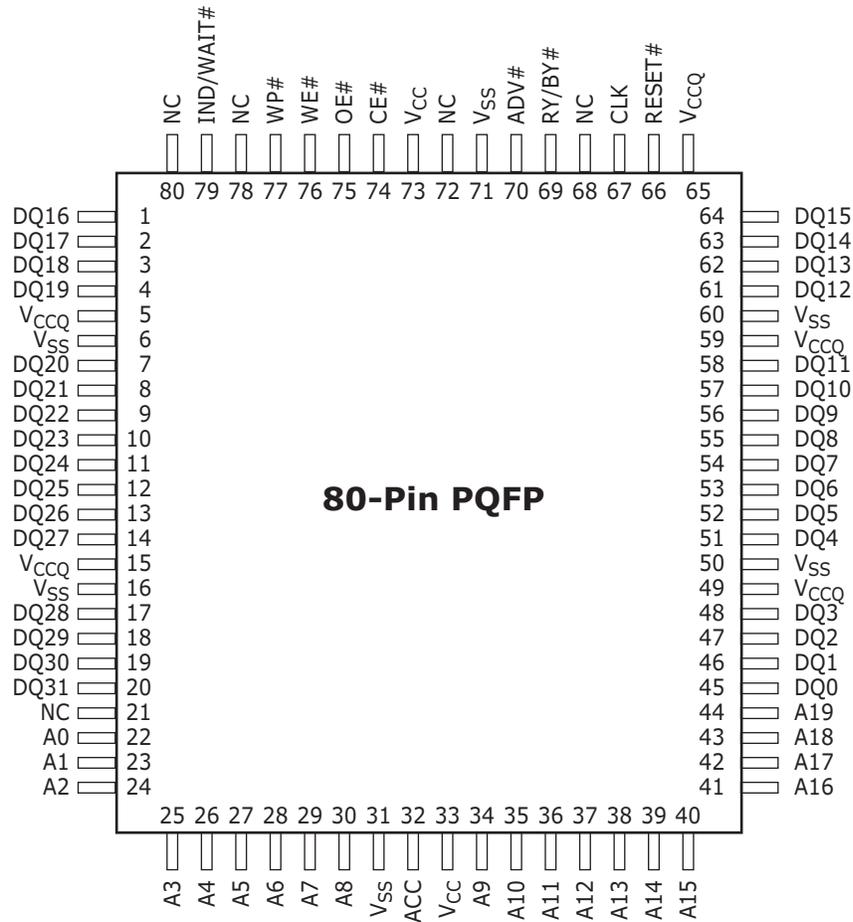

Note: Address bus is A19-A0 for 32 Mb device, A18-A0 for 16 Mb device. Data bus is D31-DQ0.

4 Block Diagram of Simultaneous Read/Write Circuit

5 Physical Dimensions/Connection Diagrams

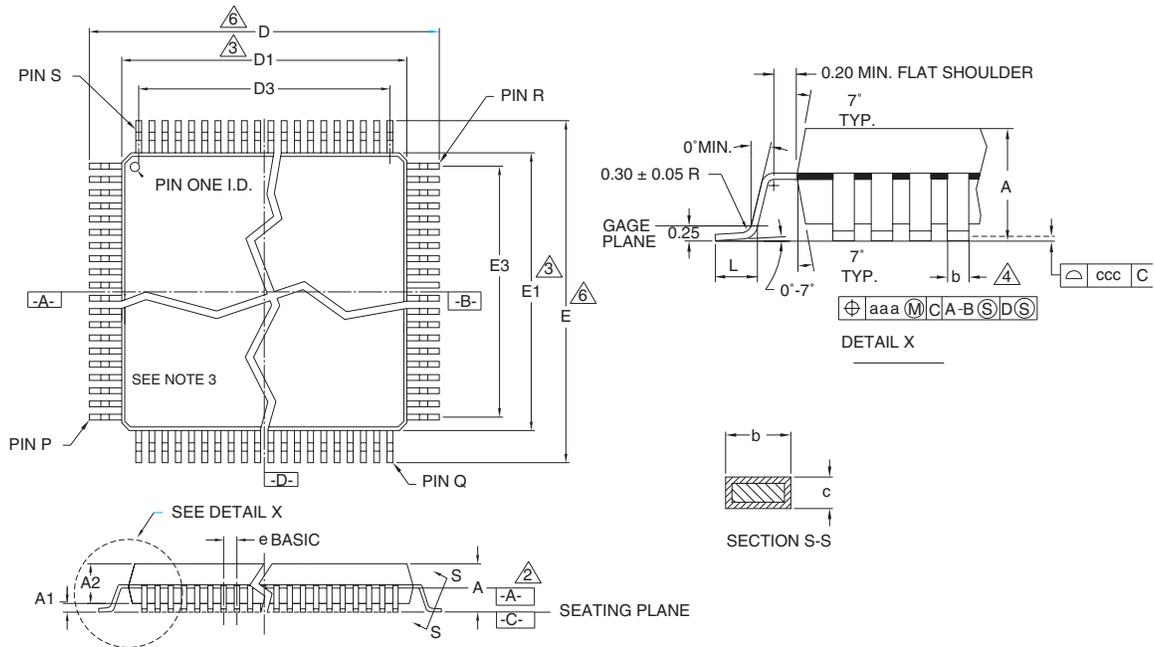

5.1 80-Pin PQFP Connection Diagram

Notes:

1. On 16 Mb device, pin 44 (A19) is NC.
2. Pin 69 (RY/BY#) is Open Drain and requires an external pull-up resistor.

5.2 PRQ080–80-Lead Plastic Quad Flat Package Physical Dimensions

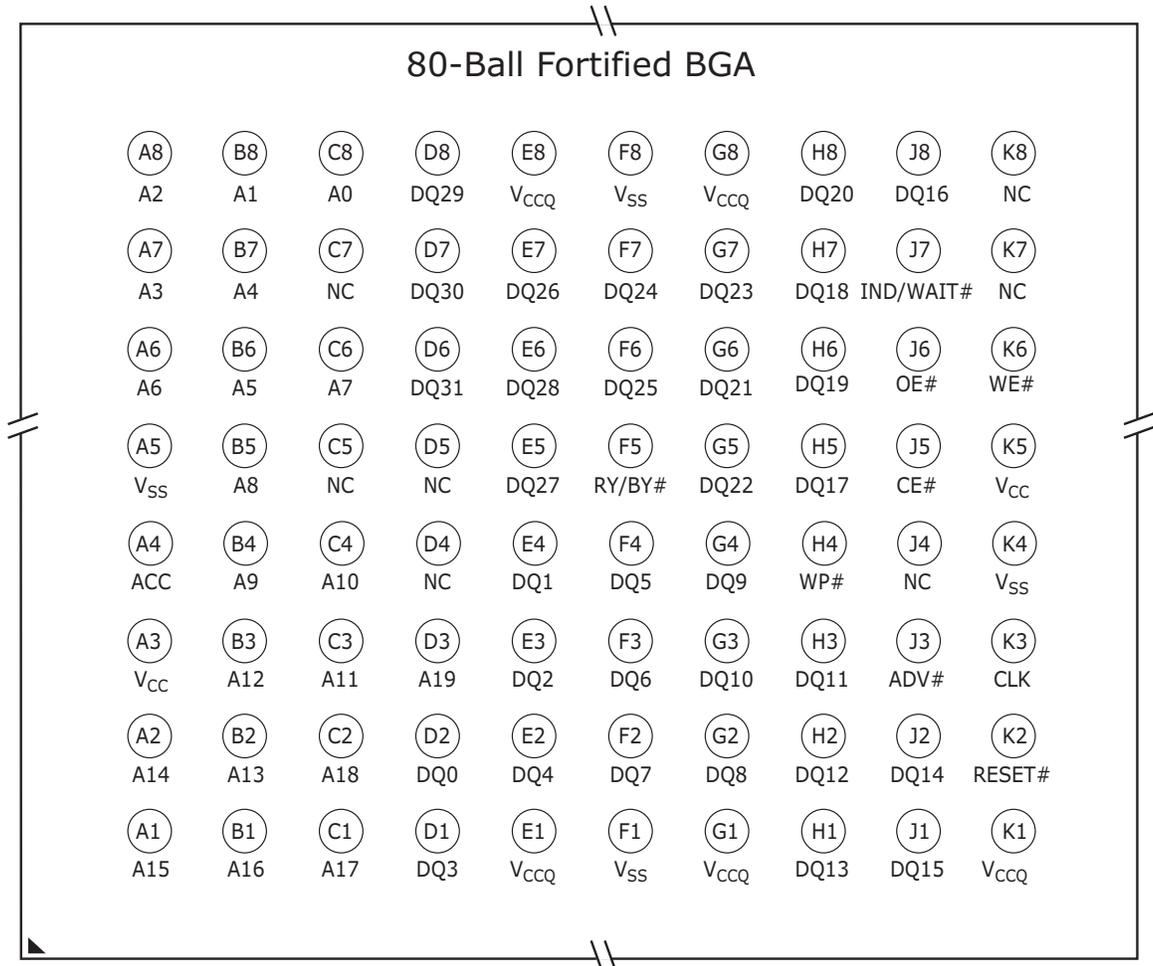

| PACKAGE | PQR 080 | | | NOTES |
|---------|---------------|-------|-------|-------------------|
| JEDEC | MO-108(B)CB-1 | | | |
| SYMBOL | MIN | NOM | MAX | |

| E | 23.00 | 23.20 | 23.40 | |
| E1 | 19.90 | 20.00 | 20.10 | SEE NOTE 3 |
| E3 | -- | 18.40 | -- | REFERENCE |
| aaa | --- | 0.20 | --- | |
| ccc | 0.10 | | | |
| L | 0.73 | 0.88 | 1.03 | |
| P | 24 | | | |
| Q | 40 | | | |
| R | 64 | | | |
| S | 80 | | | |

NOTES:

- ALL DIMENSIONS AND TOLERANCES CONFORM TO ANSI Y14.5M-1982.
- DATUM PLANE [-A-] IS LOCATED AT THE MOLD PARTING LINE AND IS COINCIDENT WITH THE BOTTOM OF THE LEAD WHERE THE LEAD EXITS THE PLASTIC BODY.
- DIMENSIONS "D1" AND "E1" DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE PROTRUSION IS 0.25 mm PER SIDE. DIMENSIONS "D1" AND "E1" INCLUDE MOLD MISMATCH AND ARE DETERMINED AT DATUM PLANE [-A-].
- DIMENSION "B" DOES NOT INCLUDE DAMBAR PROTRUSION.
- CONTROLLING DIMENSIONS: MILLIMETER.
- DIMENSIONS "D" AND "E" ARE MEASURED FROM BOTH INNERMOST AND OUTERMOST POINTS.
- DEVIATION FROM LEAD-TIP TRUE POSITION SHALL BE WITHIN ± 0.0076 mm FOR PITCH > 0.5 mm AND WITHIN ± 0.04 FOR PITCH ≤ 0.5 mm.
- LEAD COPLANARITY SHALL BE WITHIN: (REFER TO 06-500)
1 - 0.10 mm FOR DEVICES WITH LEAD PITCH OF 0.65 - 0.80 mm
2 - 0.076 mm FOR DEVICES WITH LEAD PITCH OF 0.50 mm.
COPLANARITY IS MEASURED PER SPECIFICATION 06-500.
- HALF SPAN (CENTER OF PACKAGE TO LEAD TIP) SHALL BE WITHIN ± 0.0085 ".

3213/38.4C

5.3 80-Ball Fortified BGA Connection Diagrams

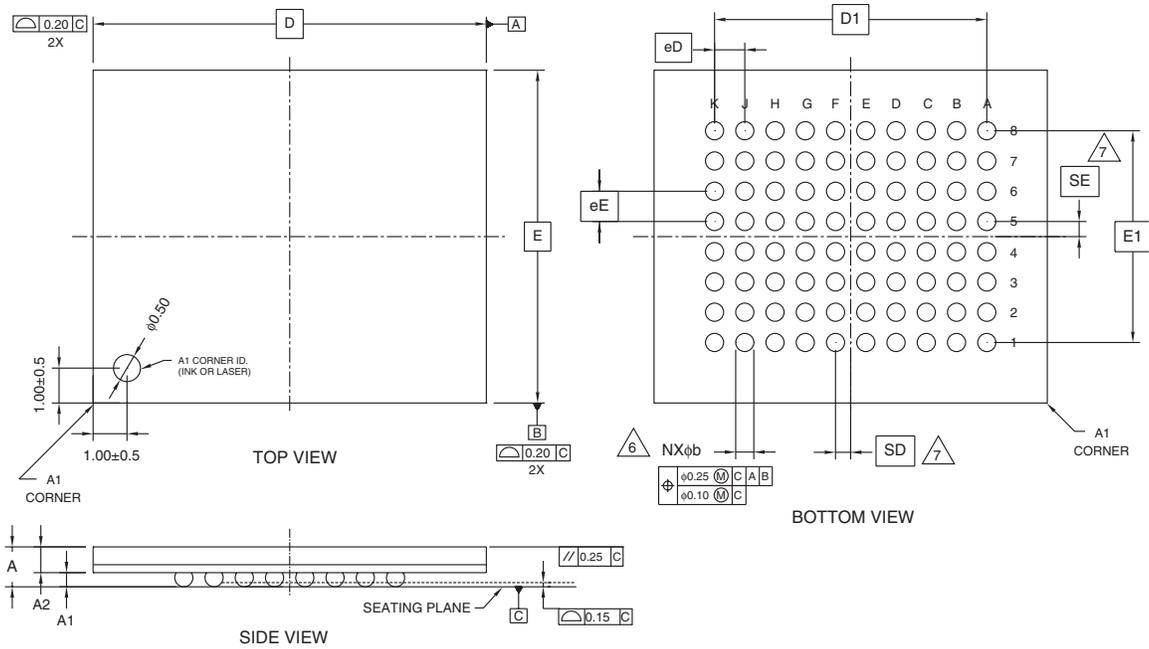

Notes:

1. On 16 Mb device, ball D3 (A19) is NC.
2. Ball F5 (RY/BY#) is Open Drain and requires an external pull-up resistor.

5.3.1 Special Package Handling Instructions

Special handling is required for Flash Memory products in molded packages (BGA). The package and/or data integrity may be compromised if the package body is exposed to temperatures above 150°C for prolonged periods of time.

5.4 LAA080–80-ball Fortified Ball Grid Array (13 x 11 mm) Physical Dimensions

| PACKAGE | LAA 080 | | | NOTE |
|---------|--------------------------|------|------|--------------------------|
| JEDEC | N/A | | | |
| | 13.00 x 11.00 mm PACKAGE | | | |
| SYMBOL | MIN | NOM | MAX | |
| A | -- | -- | 1.40 | PROFILE HEIGHT |
| A1 | 0.40 | -- | -- | STANDOFF |
| A2 | 0.60 | -- | -- | BODY THICKNESS |
| D | 13.00 BSC. | | | BODY SIZE |
| E | 11.00 BSC. | | | BODY SIZE |
| D1 | 9.00 BSC. | | | MATRIX FOOTPRINT |
| E1 | 7.00 BSC. | | | MATRIX FOOTPRINT |
| MD | 10 | | | MATRIX SIZE D DIRECTION |
| ME | 8 | | | MATRIX SIZE E DIRECTION |
| N | 80 | | | BALL COUNT |
| φb | 0.50 | 0.60 | 0.70 | BALL DIAMETER |
| eD | 1.00 BSC. | | | BALL PITCH - D DIRECTION |
| eE | 1.00 BSC. | | | BALL PITCH - E DIRECTION |
| SD/SE | 0.50 BSC | | | SOLDER BALL PLACEMENT |

- NOTES:**
- DIMENSIONING AND TOLERANCING METHODS PER ASME Y14.5M-1994.
 - ALL DIMENSIONS ARE IN MILLIMETERS.
 - BALL POSITION DESIGNATION PER JESD 95-1, SPP-010 (EXCEPT AS NOTED).
 - e REPRESENTS THE SOLDER BALL GRID PITCH.
 - SYMBOL "MD" IS THE BALL ROW MATRIX SIZE IN THE "D" DIRECTION. SYMBOL "ME" IS THE BALL COLUMN MATRIX SIZE IN THE "E" DIRECTION. N IS THE TOTAL NUMBER OF SOLDER BALLS.
 - DIMENSION "b" IS MEASURED AT THE MAXIMUM BALL DIAMETER IN A PLANE PARALLEL TO DATUM C.
 - SD AND SE ARE MEASURED WITH RESPECT TO DATUMS A AND B AND DEFINE THE POSITION OF THE CENTER SOLDER BALL IN THE OUTER ROW. WHEN THERE IS AN ODD NUMBER OF SOLDER BALLS IN THE OUTER ROW PARALLEL TO THE D OR E DIMENSION, RESPECTIVELY, SD OR SE = 0.000. WHEN THERE IS AN EVEN NUMBER OF SOLDER BALLS IN THE OUTER ROW, SD OR SE = $e/2$
 - N/A
 - "+" INDICATES THE THEORETICAL CENTER OF DEPOPULATED BALLS.

7 Product Overview

The S29CD-J and S29CL-J families consist of 32 Mb and 16 Mb, 2.6 Volts-only (CD-J) or 3.3 Volts-only (CL-J), simultaneous read/write, dual boot burst mode Flash devices optimized for today's automotive designs.

These devices are organized in 1,048,576 double words (32Mb) or 524,288 double words (16Mb) and are capable of linear burst read (2, 4, or 8 double words) with or without wraparound. (Note that 1 double word = 32 bits.) These products also offer single word programming with program/erase suspend and resume functionality. Additional features include:

- Advanced Sector Protection methods for protecting sectors as required.
- 256 bytes of Secured Silicon area for storing customer or factory secured information. The Secured Silicon Sector is One-Time Programmable.
- Electronic marking.

7.1 Memory Map

The S29CD-J and S29CL-J devices consist of two banks organized as shown in [Table 7.1](#), [Table 7.2](#), [Table 7.3](#) and [Table 7.4](#).

Table 7.1 S29CD016J/CL016J (Top Boot)Sector and Memory Address Map

Notes:

1. This sector has the additional WP# pin sector protection feature.
2. The bank address is determined by A19 and A18. BA = 00, 01, or 10 for Bank 0 and BA = 11 for Bank 1.
3. The Secured Silicon Sector overlays this sector when enabled.

8 Device Operations

This section describes the read, program, erase, simultaneous read/write operations, and reset features of the Flash devices.

Operations are initiated by writing specific commands or a sequence with specific address and data patterns into the command register (see Table 8.1). The command register itself does not occupy any addressable memory location; rather, it is composed of latches that store the commands, along with the address and data information needed to execute the command. The contents of the register serve as input to the internal state machine; the state machine outputs dictate the function of the device. Writing incorrect address and data values or writing them in an improper sequence may place the device in an unknown state, in which case the system must write the reset command in order to return the device to the reading array data mode.

8.1 Device Operation Table

The device must be set up appropriately for each operation. Table 8.1 describes the required state of each control pin for any particular operation.

Table 8.1 Device Bus Operation

| Operation | CE# | OE# | WE# | RESET# | CLK | ADV# | Addresses | Data (DQ0–DQ31) |
|---|-----|-----|-----|--------|---|---|--|----------------------------------|
| Read | L | L | H | H | X | X | A _{IN} | D _{OUT} |
| Asynchronous Write | L | H | L | H | X | X | A _{IN} | D _{IN} |
| Synchronous Write | L | H | L | H |  |  | A _{IN} | D _{IN} |
| Standby (CE#) | H | X | X | H | X | X | X | HIGH Z |
| Output Disable | L | H | H | H | X | X | HIGH Z | HIGH Z |
| Reset | X | X | X | L | X | X | X | HIGH Z |
| PPB Protection Status (Note 2) | L | L | H | H | X | X | Sector Address, A9 = V _{ID} , A7 – A0 = 02h | 00000001h, (protected) A6 = H |
| | | | | | | | | 00000000h (unprotect) A6 = L |
| Burst Read Operations | | | | | | | | |
| Load Starting Burst Address | L | X | H | H |  |  | A _{IN} | X |
| Advance Burst to next address with appropriate Data presented on the Data bus | L | L | H | H |  | H | X | Burst Data Out |
| Terminate Current Burst Read Cycle | H | X | H | H |  | X | X | HIGH Z |
| Terminate Current Burst Read Cycle with RESET# | X | X | H | L | X | X | X | HIGH Z |
| Terminate Current Burst Read Cycle; Start New Burst Read Cycle | L | H | H | H |  |  | A _{IN} | X |

Legend: L = Logic Low = V_{IL}, H = Logic High = V_{IH}, X = Don't care.

Notes:

1. WP# controls the two outermost sectors of the top boot block or the two outermost sectors of the bottom boot block.
2. DQ0 reflects the sector PPB (or sector group PPB) and DQ1 reflects the DYB

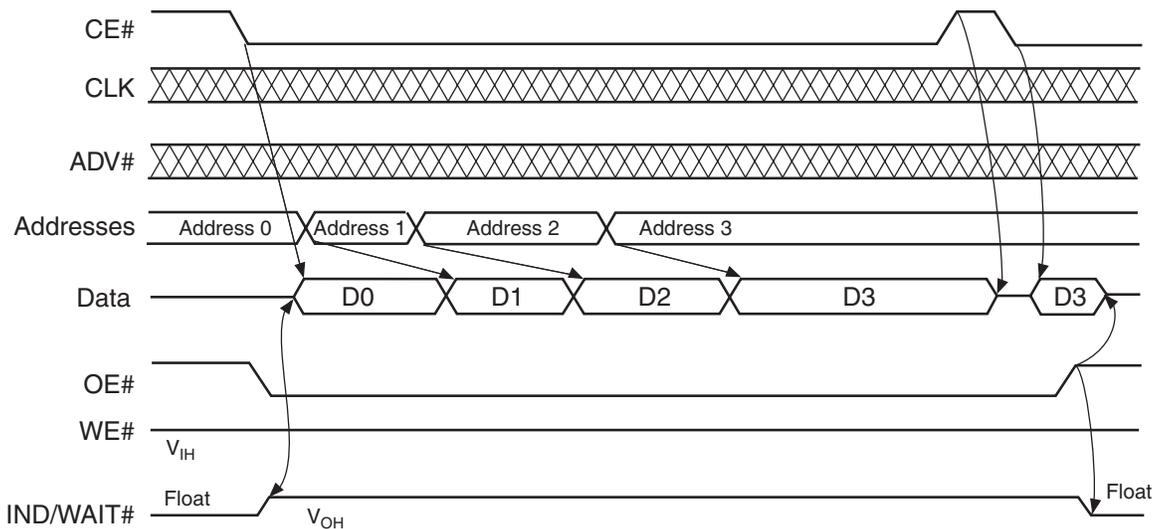

8.2 Asynchronous Read

All memories require access time to output array data. In an asynchronous read operation, data is read from one memory location at a time. Addresses are presented to the device in random order, and the propagation delay through the device causes the data on its outputs to arrive asynchronously with the address on its inputs.

The internal state machine is set for asynchronously reading array data upon device power-up, or after a hardware reset. This ensures that no spurious alteration of the memory content occurs during the power transition. No command is necessary in this mode to obtain array data. Standard microprocessor read cycles that assert valid addresses on the device address inputs produce valid data on the device data outputs. The device remains enabled for read access until the command register contents are altered.

The device has two control functions which must be satisfied in order to obtain data at the outputs. CE# is the power control and should be used for device selection (CE# must be set to V_{IL} to read data). OE# is the output control and should be used to gate data to the output pins if the device is selected (OE# must be set to V_{IL} in order to read data). WE# should remain at V_{IH} (when reading data).

Address access time (t_{ACC}) is equal to the delay from stable addresses to valid output data. The chip enable access time (t_{CE}) is the delay from the stable addresses and stable CE# to valid data at the output pins. The output enable access time (t_{OE}) is the delay from the falling edge of OE# to valid data at the output pins (assuming the addresses have been stable for at least a period of $t_{ACC}-t_{OE}$ and CE# has been asserted for at least $t_{CE}-t_{OE}$ time). Figure 8.1 shows the timing diagram of an asynchronous read operation.

Note: Operation is shown for the 32-bit data bus. For the 16-bit data bus, A-1 is required.

Figure 8.1 Asynchronous Read Operation

Refer to *Asynchronous Operations* on page 56 for timing specifications and to *Figure 18.2, Conventional Read Operations Timings*, on page 56 for another timing diagram. ICC1 in the DC Characteristics table represents the active current specification for reading array data.

8.3 Hardware Reset (RESET#)

The RESET# pin is an active low signal that is used to reset the device under any circumstances. A logic “0” on this input forces the device out of any mode that is currently executing back to the reset state. RESET# may be tied to the system reset circuitry. A system reset would thus also reset the device. To avoid a potential bus contention during a system reset, the device is isolated from the DQ data bus by tristating the data outputs for the duration of the RESET pulse. All data outputs are “don’t care” during the reset operation.

If RESET# is asserted during a program or erase operation, the RY/BY# output remains low until the reset operation is internally complete. The RY/BY# pin can be used to determine when the reset operation is complete. Since the device offers simultaneous read/write operation, the host system may read a bank after a period of $t_{\text{READY}2}$, if the bank was in the read/reset mode at the time RESET# was asserted. If one of the banks was in the middle of either a program or erase operation when RESET# was asserted, the user must wait a period of t_{READY} before accessing that bank.

Asserting RESET# during a program or erase operation leaves erroneous data stored in the address locations being operated on at the time of device reset. These locations need updating after the reset operation is complete. See Section 18.4 for timing specifications.

Asserting RESET# active during V_{CC} and V_{IO} power-up is required to guarantee proper device initialization until V_{CC} and V_{IO} have reached their steady state voltages. See Section 18.1.

8.4 Synchronous (Burst) Read Mode & Configuration Register

When a series of adjacent addresses need to be read from the device, the synchronous (or burst read) mode can be used to significantly reduce the overall time needed for the device to output array data. After an initial access time required for the data from the first address location, subsequent data is output synchronized to a clock input provided by the system.

The device offers a linear method of burst read operation which is discussed in *2-, 4-, 8- Double Word Linear Burst Operation* on page 24.

Since the device defaults to asynchronous read mode after power-up or a hardware reset, the configuration register must be set in order to enable the burst read mode. Other Configuration Register settings include the number of wait states to insert before the initial word (t_{IACC}) of each burst access and when RDY indicates that data is ready to be read. Prior to entering the burst mode, the system first determines the configuration register settings (and read the current register settings if desired via the Read Configuration Register command sequence), then write the configuration register command sequence. See *Configuration Register* on page 26, and *Table 20.1, Memory Array Command Definitions (x32 Mode)*, on page 71 for further details. Once the configuration register is written to enable burst mode operation, all subsequent reads from the array are returned using the burst mode protocols.

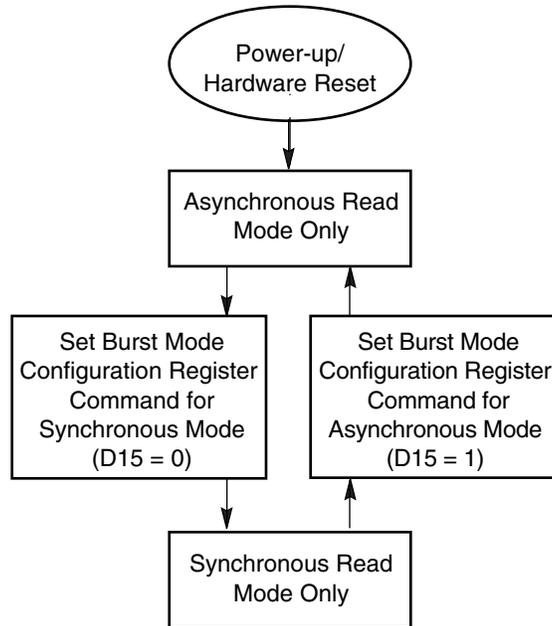

Figure 8.2 Synchronous/Asynchronous State Diagram

The device outputs the initial word subject to the following operational conditions:

- t_{IACC} specification: The time from the rising edge of the first clock cycle after addresses are latched to valid data on the device outputs.
- Configuration register setting CR13-CR10: The total number of clock cycles (wait states) that occur before valid data appears on the device outputs. The effect is that t_{IACC} is lengthened.

Like the main memory access, the Secured Silicon Sector memory is accessed with the same burst or asynchronous timing as defined in the Configuration Register. However, the user must recognize burst operations past the 256 byte Secured Silicon boundary returns invalid data.

Burst read operations occur only to the main flash memory arrays. The Configuration Register and protection bits are treated as single cycle reads, even when burst mode is enabled. Read operations to these locations results in the data remaining valid while $OE\#$ is at V_{IL} , regardless of the number of CLK cycles applied to the device.

8.4.1 2-, 4-, 8- Double Word Linear Burst Operation

In a linear burst read operation, a fixed number of words (2, 4, or 8 double words) are read from consecutive addresses that are determined by the group within which the starting address falls. Note that 1 double word = 32 bits. See Table 8.2 for all valid burst output sequences.

The IND/WAIT# signal, or End of Burst Indicator signal, transitions active (V_{IL}) during the last transfer of data in a linear burst read before a wrap around. This transition indicates that the system should initiate another ADV# to start the next burst access. If the system continues to clock the device, the next access wraps around to the starting address of the previous burst access. The IND/WAIT# signal is floating when not active.

Table 8.2 32- Bit Linear and Burst Data Order

| Data Transfer Sequence (Independent of the WORD# pin) | Output Data Sequence (Initial Access Address) (x16) |
|---|---|
| Two Linear Data Transfers | 0-1 (A0 = 0) 1-0 (A0 = 1) |
| Four Linear Data Transfers | 0-1-2-3 (A0:A-1/A1-A0 = 00) 1-2-3-0 (A0:A-1/A1-A0 = 01) 2-3-0-1 (A:A-1/A1-A0 = 10) 3-0-1-2 (A0:A-1/A1-A0 = 11) |
| Eight Linear Data Transfers | 0-1-2-3-4-5-6-7 (A1:A-1A2-A0 = 000) 1-2-3-4-5-6-7-0 (A1:A-1/A2-A0 = 001) 2-3-4-5-6-7-0-1 (A1:A-1/A2-A0 = 010) 3-4-5-6-7-0-1-2 (A1:A-1/A2-A0 = 011) 4-5-6-7-0-1-2-3 (A1:A-1/A2-A0 = 100) 5-6-7-0-1-2-3-4 (A1:A-1/A2-A0 = 101) 6-7-0-1-2-3-4-5 (A1:A-1/A2-A0 = 110) 7-0-1-2-3-4-5-6 (A1:A-1/A2-A0 = 111) |

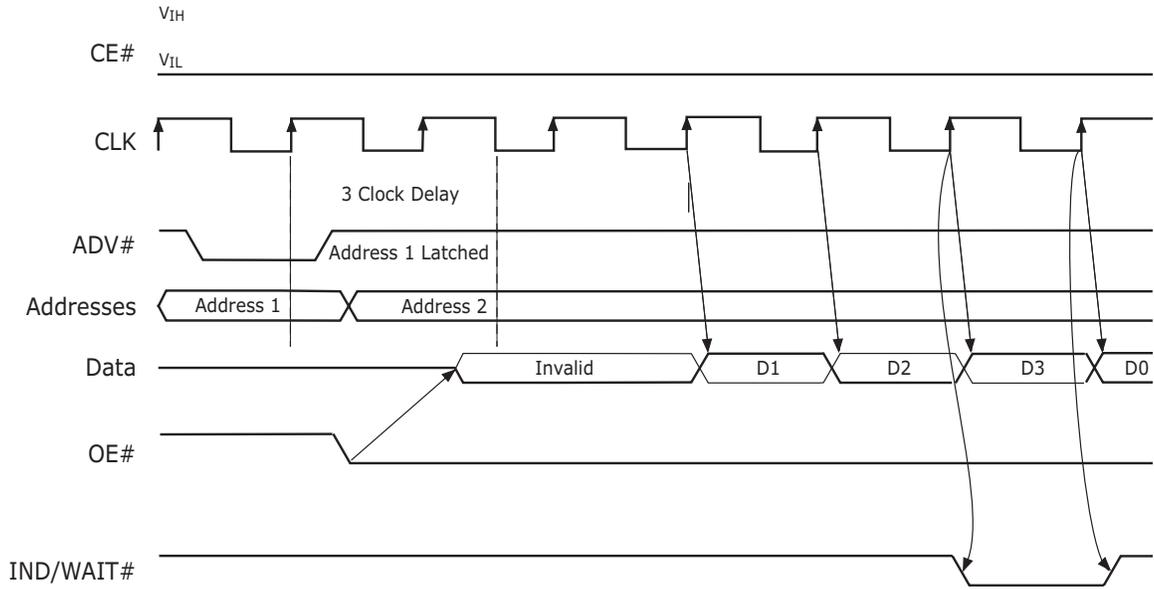

The IND/WAIT# signal is controlled by the OE# signal. If OE# is at V_{IH} , the IND/WAIT# signal floats and is not driven. If OE# is at V_{IL} , the IND/WAIT# signal is driven at V_{IH} until it transitions to V_{IL} , indicating the end of the burst sequence. Table 8.3 lists the valid combinations of the Configuration Register bits that impact the IND/WAIT# timing. See Figure 8.3 for the IND/WAIT# timing diagram.

Notes:

- The default configuration in the Control Register for Bit 6 is "1," indicating that the device delivers data on the rising edge of the CLK signal.
- The device is capable of holding data for one CLK cycle.
- If RESET# is asserted low during a burst access, the burst access is immediately terminated and the device defaults back to asynchronous read mode. When this happens, the DQ data bus signal floats and the Configuration Register contents are reset to their default conditions.
- CE# must meet the required burst read setup times for burst cycle initiation. If CE# is taken to V_{IH} at any time during the burst linear or burst cycle, the device immediately exits the burst sequence and floats the DQ bus signal.
- Restarting a burst cycle is accomplished by taking CE# and ADV# to V_{IL} .
- A burst access is initiated and the address is latched on the first rising CLK edge when ADV# is active or upon a rising ADV# edge, whichever occurs first. If the ADV# signal is taken to V_{IL} prior to the end of a linear burst sequence, the previous address is discarded and subsequent burst transfers are invalid. A new burst is initiated when ADV# transitions back to V_{IH} before a clock edge.
- The OE# (Output Enable) pin is used to enable the linear burst data on the DQ data bus pin. De-asserting the OE# pin to V_{IH} during a burst operation floats the data bus, but the device continues to operate internally as if the burst sequence continues until the linear burst is complete. The OE# pin does not halt the burst sequence. The DQ bus remains in the float state until OE# is taken to V_{IL} .
- Halting the burst sequence is accomplished by either taking CE# to V_{IH} or re-issuing a new ADV# pulse.

Table 8.3 Valid Configuration Register Bit Definition for IND/WAIT#

| CR9 (DOC) | CR8 (WC) | CR6 (CC) | Definition |
|-----------|----------|----------|--|
| 0 | 0 | 1 | IND/WAIT# = V_{IL} for 1-CLK cycle, Active on last transfer, Driven on rising CLK edge |
| 0 | 1 | 1 | IND/WAIT# = V_{IL} for 1-CLK cycle, Active on second to last transfer, Driven on rising CLK edge |

Note: Operation is shown for the 32-bit data bus. Figure shown with 3-CLK initial access delay configuration, linear address, 4-doubleword burst, output on rising CLD edge, data hold for 1-CLK, IND/WAIT# asserted on the last transfer before wrap-around.

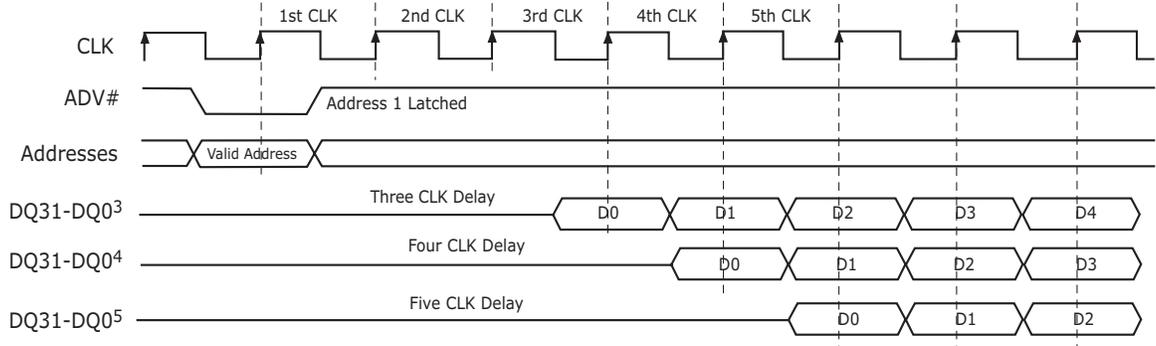

Figure 8.3 End of Burst Indicator (IND/WAIT#) Timing for Linear 8-Word Burst Operation

8.4.2 Initial Burst Access Delay

Initial Burst Access Delay is defined as the number of clock cycles that must elapse from the first valid clock edge after ADV# assertion (or the rising edge of ADV#) until the first valid CLK edge when the data is valid. Burst access is initiated and the address is latched on the first rising CLK edge when ADV# is active or upon a rising ADV# edge, whichever comes first. The Initial Burst Access Delay is determined in the Configuration Register (CR13-CR10). Refer to [Table 8.5](#) for the initial access delay configurations under CR13-CR10. See [Figure 8.4](#) for the Initial Burst Delay Control timing diagram. Note that the Initial Access Delay for a burst access has no effect on asynchronous read operations.

Table 8.4 Burst Initial Access Delay

| CR13 | CR12 | CR11 | CR10 | Initial Burst Access (CLK cycles) |
|------|------|------|------|-----------------------------------|
| 0 | 0 | 0 | 1 | 3 |
| 0 | 0 | 1 | 0 | 4 |
| 0 | 0 | 1 | 1 | 5 |
| 0 | 1 | 0 | 0 | 6 |
| 0 | 1 | 0 | 1 | 7 |
| 0 | 1 | 1 | 0 | 8 |
| 0 | 1 | 1 | 1 | 9 |

Notes:

1. Burst access starts with a rising CLK edge and when ADV# is active.
2. Configurations register 6 is always set to 1 (CR6 = 1). Burst starts and data outputs on the rising CLK edge.
3. CR [13-10] = 1 or three clock cycles
4. CR [13-10] = 2 or four clock cycles
5. CR [13-10] = 3 or five clock cycles

Figure 8.4 Initial Burst Delay Control

8.4.3 Configuration Register

The configuration register sets various operational parameters associated with burst mode. Upon power-up or hardware reset, the device defaults to the asynchronous read mode and the configuration register settings are in their default state. (See [Table 8.6](#) for the default Configuration Register settings.) The host system determines the proper settings for the entire configuration register, and then execute the Set Configuration Register command sequence before attempting burst operations. The configuration register is not reset after deasserting CE#.

The Configuration Register does not occupy any addressable memory location, but rather, is accessed by the Configuration Register commands. The Configuration Register is readable at any time, however, writing the Configuration Register is restricted to times when the Embedded Algorithm™ is not active. If the user attempts to write the Configuration Register while the Embedded Algorithm™ is active, the write operation is ignored and the contents of the Configuration Register remain unchanged.

The Configuration Register is a 16 bit data field which is accessed by DQ15–DQ0. During a read operation, DQ31–DQ16 returns all zeroes. Also, the Configuration Register reads operate the same as the Autoselect command reads. When the command is issued, the bank address is latched along with the command. Read operations to the bank that was specified during the Configuration Register read command return Configuration Register contents. Read operations to the other bank return flash memory data. Either bank address is permitted when writing the Configuration Register read command.

The configuration register can be read with a four-cycle command sequence. See *Command Definitions* on [page 71](#) for sequence details.

Table 8.5 describes the Configuration Register settings.

Table 8.5 Configuration Register

| Configuration Register | |
|--|--|
| CR15 = Read Mode (RM) 0 = Synchronous Burst Reads Enabled 1 = Asynchronous Reads Enabled (Default) | |
| CR14 = Reserved for Future Enhancements These bits are reserved for future use. Set these bits to 0. | |

8.5 Autoselect

The autoselect mode provides manufacturer and device identification, and sector protection verification, through identifier codes output on DQ7–DQ0. This mode is primarily intended for programming equipment to automatically match a device to be programmed with its corresponding programming algorithm. However, the autoselect codes can also be accessed in-system through the command register.

When using programming equipment, the autoselect mode requires VID on address pin A9. Address pins A6, A1, and A0 must be as shown in Table 8.7. In addition, when verifying sector protection, the sector address must appear on the appropriate highest order address bits. Table 8.7

shows the remaining address bits that are don't care. When all necessary bits have been set as required, the programming equipment may then read the corresponding identifier code on DQ7–DQ0.

In order to access the autoselect codes in-system, the host system can issue the autoselect command via the command. This method does not require VID. See *Command Definitions on page 71* for details on using the autoselect mode. Autoselect mode can be used in either synchronous (Burst) mode or asynchronous (Non Burst) mode.

The system must write the reset command to exit the autoselect mode and return to reading the array data. See [Table 8.7](#) for command sequence details.

Table 8.7 S29CD-J & S29CL-J Flash Family Autoselect Codes (High Voltage Method)

| Description | CE# | OE# | WE# | A19 to A11 | A10 | A9 | A8 | A7 | A6 | A5 to A4 | A3 | A2 | A1 | A0 | DQ7 to DQ0 |
|---------------------------|--------------|-----|-----|------------|-----|-----------------|-----------------|----|----|----------|----|----|----|----|---|
| Manufacturer ID: Spansion | L | L | H | X | X | V _{ID} | X | X | L | X | X | X | L | L | 0001h |
| Autoselect Device Code | Read Cycle 1 | L | L | H | X | X | V _{ID} | X | L | L | X | L | L | L | 007Eh |
| | Read Cycle 2 | L | L | H | X | X | V _{ID} | X | L | L | L | H | H | H | 08h or 36h for CD016J 46h for CL016J 09h for CD032J 49h for CL032J |
| | Read Cycle 3 | L | L | H | X | X | V _{ID} | X | L | L | L | H | H | H | 0000h Top Boot Option 0001h Bottom Boot Option |
| PPB Protection Status | L | L | H | SA | X | V _{ID} | X | L | L | L | L | L | H | L | 0000h (unprotected) |
| | | | | | | | | | | | | | | | 0001h (protected) |

Legend: L = Logic Low = V_{IL}, H = Logic High = V_{IH}, SA = Sector Address, X = Don't care.

Note: The autoselect codes can also be accessed in-system via command sequences. See [Table 20.2](#).

8.6 Versatile/O™ (V_{IO}) Control

The Versatile/O (V_{IO}) control allows the host system to set the voltage levels that the device generates at its data outputs and the voltages tolerated at its data inputs to the same voltage level that is asserted on the V_{IO} pin. The output voltage generated on the device is determined based on the V_{IO} (V_{CCQ}) level. For the 2.6 V (CD-J), a V_{IO} of 1.65 V - 3.6 V (CD032J has a V_{IO} of 1.65V to 2.75V) allows the device to interface with I/Os lower than 2.5 V. For a 3.3 V V_{CC} (CL-J), a V_{IO} of 1.65 V-3.60 V allows the device to interface with I/Os lower than 3.0 V.

8.7 Program/Erase Operations

These devices are capable of several modes of programming and or erase operations which are described in detail in the following sections. However, prior to any programming and or erase operation, devices must be set up appropriately as outlined in the configuration register ([Table 8.5 on page 27](#)). During a synchronous write operation, to write a command or command sequence (including programming data to the device and erasing sectors of memory), the system must drive AVD# and CE# to V_{IL}, and OE# to V_{IH} when providing an address to the device, and drive WE# and CE# to V_{IL}, and OE# to V_{IH} when writing commands or programming data.

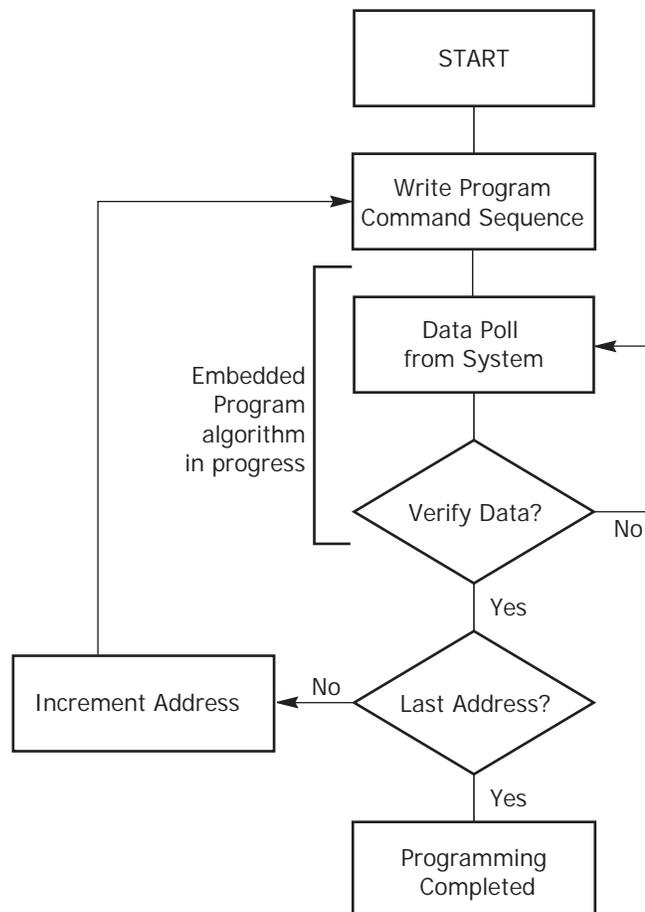

8.7.1 Programming

Programming is a four-bus-cycle operation. The program command sequence is initiated by writing two unlock write cycles, followed by the program setup command. The program address and data are written next, which in turn initiate the Embedded Program algorithm. The system is not

required to provide further controls or timings. The device automatically generates the program pulses and verifies the programmed cell margin. *Command Definitions on page 71* shows the address and data requirements for the program command sequence.

Note the following:

- When the Embedded Program algorithm is complete, the device returns to the read mode and address are no longer latched. An address change is required to begin reading valid array data.
- The system can determine the status of the program operation by using DQ7, DQ6 or RY/BY#. Refer to *Write Operation Status on page 33* for information on these status bits.
- A "0" cannot be programmed back to a "1." Attempting to do so may halt the operation and set DQ5 to 1, or cause the Data# Polling algorithm to indicate the operation was successful. . A succeeding read shows that the data is still "0." Only erase operations can convert a "0" to a "1."
- Any commands written to the device during the Embedded Program Algorithm are ignored except the Program Suspend command.
- A hardware reset immediately terminates the program operation; the program command sequence should be re-initiated once the device has returned to the read mode, to ensure data integrity.

Note: See [Table 19.1](#) and [Table 20.2](#) for program command sequence.

Figure 8.5 Program Operation

8.7.2 Sector Erase

The sector erase function erases one or more sectors in the memory array. (See [Table 20.1, Memory Array Command Definitions \(x32 Mode\), on page 71](#) and [Figure 8.6, Erase Operation, on page 31](#).) The device does not require the system to preprogram prior to erase. The Embedded Erase algorithm automatically programs and verifies the entire memory for an all-zero data pattern prior to electrical erase. After a successful sector erase, all locations within the erased sector contain FFFFh. The system is not required to provide any controls or timings during these operations.

After the command sequence is written, a sector erase time-out of no less than 80 μ s occurs. During the time-out period, additional sector addresses and sector erase commands may be written. Loading the sector erase buffer may be done in any sequence, and the number of sectors may be from one sector to all sectors. The time between these additional cycles must be less than 80 μ s. Any sector erase address and command following the exceeded time-out (80 μ s) may or may not be accepted. A time-out of 80 μ s from the rising edge of the last WE# (or CE#) initiates the execution of the Sector Erase command(s). If another falling edge of the WE# (or CE#) occurs within the 80 μ s time-out window, the timer is reset. Any command other than Sector Erase or Erase Suspend during the time-out period resets that bank to the read mode. The system can monitor DQ3 to determine if the sector erase timer has timed out (See [DQ3: Sector Erase Timer on page 39](#).) The time-out begins from the rising edge of the final WE# pulse in the command sequence.

When the Embedded Erase algorithm is complete, the bank returns to reading array data; addresses are no longer latched. The system can determine the status of the erase operation by reading DQ7 or DQ6/DQ2 in the erasing bank. Refer to [Write Operation Status on page 33](#) for information on these status bits.

Once the sector erase operation has begun, only the Erase Suspend command is valid. All other commands are ignored. However, note that a hardware reset immediately terminates the erase operation. If that occurs, the sector erase command sequence should be re-initiated once that bank has returned to reading array data, in order to ensure data integrity.

[Figure 8.6](#) illustrates the algorithm for the erase operation. Refer to [Program/Erase Operations on page 28](#) for parameters and timing diagrams.

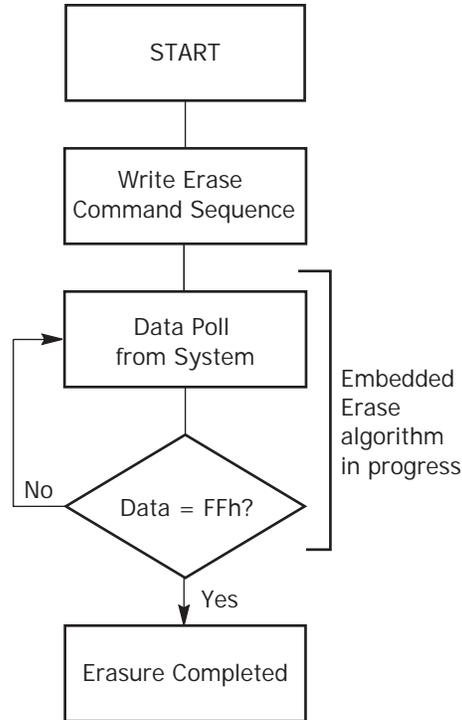

8.7.3 Chip Erase

Chip erase is a six-bus cycle operation as indicated by [Command Definitions on page 71](#). The Chip Erase command is used to erase the entire flash memory contents of the chip by issuing a single command. However, chip erase does not erase protected sectors.

This command invokes the Embedded Erase algorithm, which does not require the system to preprogram prior to erase. The Embedded Erase algorithm automatically preprograms and verifies the entire memory for an all-zero data pattern prior to electrical erase. After a successful chip erase, all locations of the chip contain FFFFh. The system is not required to provide any controls or timings during these operations. [Command Definitions on page 71](#) in the appendix shows the address and data requirements for the chip erase command sequence.

When the Embedded Erase algorithm is complete, that bank returns to the read mode and addresses are no longer latched. The system can determine the status of the erase operation by using DQ7, DQ6 or the RY/BY#. Refer to [Write Operation Status on page 33](#) for information on these status bits.

Any commands written during the chip erase operation are ignored. However, note that a hardware reset immediately terminates the erase operation. If that occurs, the chip erase command sequence should be reinitiated once that bank has returned to reading array data, to ensure data integrity.

**Notes:**

1. See [Command Definitions on page 71](#) for erase command sequence.
2. See ["DQ3: Sector Erase Timer"](#) for more information.

Figure 8.6 Erase Operation**8.7.4 Erase Suspend / Erase Resume Commands**

The Erase Suspend command allows the system to interrupt a sector erase operation and then read data from, or program data to, any sector not selected for erasure. When the Erase Suspend command is written during the sector erase time-out, the device immediately terminates the time-out period and suspends the erase operation. The bank address is required when writing this command. This command is valid only during the sector erase operation, including the minimum 80- μ s time-out period during the sector erase command sequence. The Erase Suspend command is ignored if written during the chip erase operation.

When the Erase Suspend command is written after the 80- μ s time-out period has expired and during the sector erase operation, the device takes 20 μ s maximum to suspend the erase operation.

After the erase operation has been suspended, the bank enters the erase-suspend-read mode. The system can read data from or program data to any sector that is not selected for erasure. (The device "erase suspends" all sectors selected for erasure.) Note that when the device is in the Erase Suspend mode, the Reset command is not required for read operations and is ignored.

Further nesting of erase operation is not permitted. Reading at any address within erase suspended sectors produces status information on DQ7-DQ0. The system can use DQ6 and DQ2 together, to determine if a sector is actively erasing or is erase-suspended. Refer to Table 8.8 on page 37 for information on these status bits.

A read operation from the erase-suspended bank returns polling data during the first 8 μ s after the erase suspend command is issued; read operations thereafter return array data. Read operations from the other bank return array data with no latency.

After an erase-suspended program operation is complete, the bank returns to the erase-suspend read mode. The system can determine the status of the program operation using the DQ7, DQ6, and/or RY/BY# status bits, just as in the standard program operation.

To resume the sector erase operation, the system must write the Erase Resume command. The bank address of the erase-suspended bank is required when writing this command. Further writes of the Resume command are ignored. Another Erase Suspend command can be written after the chip has resumed erasing.

The following are the allowable operations when Erase Suspend is issued under certain conditions:

For the Busy Sectors, the host system may

- Read status
- Write the Erase Resume command

For the Non Busy Sectors, the system may

- Read data
- Program data or write the Suspend/Resume Erase command

8.7.5 Program Suspend/Program Resume Commands

The Program Suspend command allows the system to interrupt an embedded programming operation so that data can read from any non-suspended sector. When the Program Suspend command is written during a programming process, the device halts the programming operation and updates the status bits.

After the programming operation has been suspended, the system can read array data from any non-suspended sector. If a read is needed from the Secured Silicon Sector area, then user must use the proper command sequences to enter and exit this region. The Sector Erase and Program Resume Command is ignored if the Secured Silicon sector is enabled.

After the Program Resume command is written, the device reverts to programming. The system can determine the status of the program operation using the DQ7, DQ6, and/or RY/BY# status bits, just as in the standard program operation. See *Write Operation Status* [on page 33](#) for more information.

The system must write the Program Resume command in order to exit the Program Suspend mode, and continue the programming operation. Further writes of the Program Resume command are ignored. Another Program Suspend command can be written after the device has resumed programming.

The following are the allowable operations when Program Suspend is issued under certain conditions:

- For the Busy Sectors, the host system may write the Program Resume command
- For the Non Busy Sectors, the system may read data

8.7.6 Accelerated Program and Erase Operations

Accelerated programming and erasing is enabled through the ACC function. This method is faster than the standard program command sequences.

The device offers accelerated program/erase operations through the ACC pin. When the system asserts V_{HH} (12V) on the ACC pin, the device automatically enters the Unlock Bypass mode. The system may then write the two-cycle Unlock Bypass program command sequence to do accelerated programming. The device uses the higher voltage on the ACC pin to accelerate the operation. Any sector that is being protected with the WP# pin is still protected during accelerated program or Erase. Removing V_{HH} from the ACC input, upon completion of the embedded program or erase operation, returns the device to normal operation.

Notes:

- In this mode, the write protection function is bypassed unless the PPB Lock Bit = 1.
- The ACC pin must not be at V_{HH} for operations other than accelerated programming and accelerated chip erase, or device damage may result.
- The ACC pin must not be left floating or unconnected; inconsistent behavior of the device may result.
- The Accelerated Program command is not permitted if the Secured Silicon sector is enabled.

8.7.7 Unlock Bypass

The device features an Unlock Bypass mode to facilitate faster programming, erasing (Sector and Chip Erase), as well as CFI commands. Once the device enters the Unlock Bypass mode, only two write cycles are required to program or erase data, instead of the normal four cycles. This results in faster total programming/erasing time.

Command Definitions on page 71 shows the requirements for the unlock bypass command sequences.

During the unlock bypass mode only the Read, Unlock Bypass Program and Unlock Bypass Reset commands are valid. To exit the unlock bypass mode, the system must issue the two-cycle unlock bypass reset command sequence, which returns the device to read mode.

Notes:

1. The Unlock Bypass Command is ignored if the Secured Silicon sector is enabled.
2. Unlike the standard program or erase commands, there is no Unlock Bypass Program/Erase Suspend or Program/Erase Resume command.

8.7.8 Simultaneous Read/Write

The simultaneous read/write feature allows the host system to read data from one bank of memory while programming or erasing in another bank of memory.

The Simultaneous Read/Write feature can be used to perform the following:

- Programming in one bank, while reading in the other bank
- Erasing in one bank, while reading in the other bank
- Programming a PPB, while reading data from the large bank or status from the small bank
- Erasing a PBB, while reading data from the large bank or status from the small bank
- Any of the above situations while in the Secured Silicon Sector Mode

The Simultaneous R/W feature can not be performed during the following modes:

- CFI Mode
- Password Program operation
- Password Verify operation

As an alternative to using the Simultaneous Read/Write feature, the user may also suspend an erase or program operation to read in another location within the same bank (except for the sector being erased).

8.8 Write Operation Status

The device provides several bits to determine the status of a program or erase operation. The following subsections describe the function of DQ7, DQ6, DQ2, DQ5, DQ3, and RY/BY#.

8.8.1 DQ7: Data# Polling

The Data# Polling bit, DQ7, indicates to the host system whether an Embedded Program or Erase algorithm is in progress or completed, or whether a bank is in Erase Suspend. Data# Polling is valid after the rising edge of the final WE# pulse in the command sequence. Note that Data# Polling returns invalid data for the address being programmed or erased.

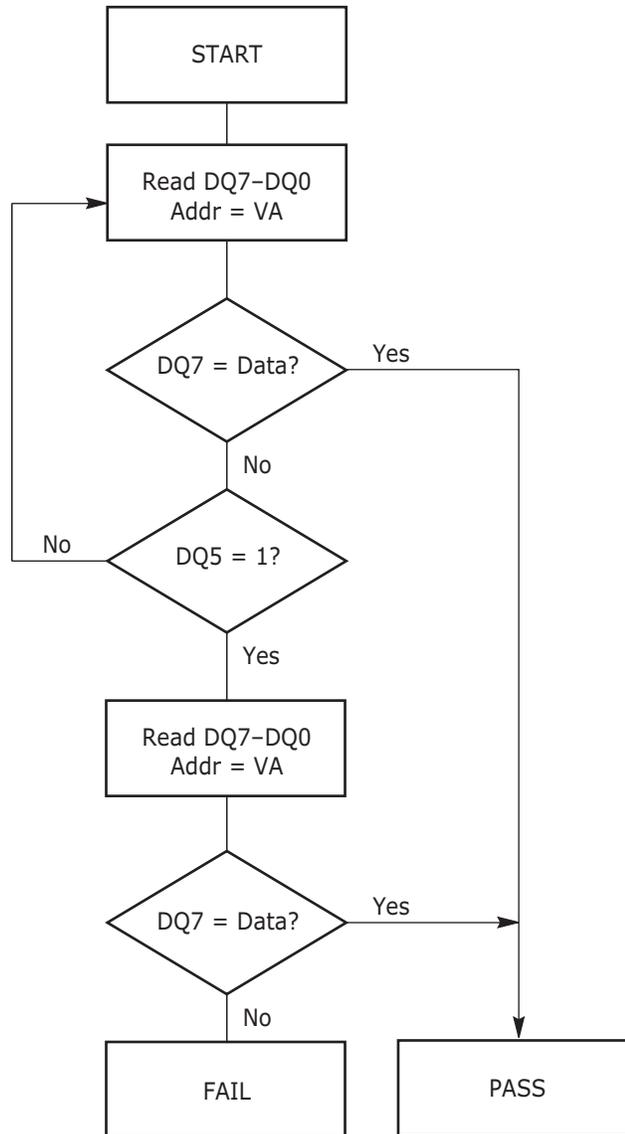

During the Embedded Program algorithm, the device outputs on DQ7 the complement of the datum programmed to DQ7. This DQ7 status also applies to programming during Erase Suspend. When the Embedded Program algorithm is complete, the device outputs the datum programmed to DQ7. The system must provide the program address to read valid status information on DQ7.

If a program address falls within a protected sector, Data# polling on DQ7 is active for approximately 1 μ s, then that bank returns to the read mode without programming the sector. If an erase address falls within a protected sector, Toggle BIT (DQ6) is active for 150 ns, then the device returns to the read mode without erasing the sector. Please note that Data# polling (DQ7) may give misleading status when an attempt is made to program or erase a protected sector.

During the Embedded Erase Algorithm, Data# polling produces a "0" on DQ7. When the Embedded Erase algorithm is complete Data# Polling produces a "1" on DQ7. The system must provide an address within any of the sectors selected for erasure to read valid status information on DQ7.

In asynchronous mode, just prior to the completion of an Embedded Program or Erase operation, DQ7 may change asynchronously with DQ6-DQ0 while Output Enable (OE#) is asserted low. That is, the device may change from providing status information to valid data on DQ7. Depending on when the system samples the DQ7 output, it may read the status or valid data. Even if the device has completed the program or erase operation and DQ7 has valid data, the data outputs on DQ6-DQ0 may be still invalid. Valid data on DQ7-DQ0 appears on successive read cycles.

See the following for more information: [Table 8.9, Write Operation Status on page 40](#) shows the outputs for Data# Polling on DQ7. [Figure 8.7, Data# Polling Algorithm, on page 35](#) shows the Data# Polling timing diagram.

**Notes:**

1. *VA = Valid address for programming. During a sector erase operation, a valid address is an address within any sector selected for erasure. During chip erase, a valid address is any non-protected sector address.*
2. *DQ7 should be rechecked even if DQ5 = 1 because DQ7 may change simultaneously with DQ5*

Figure 8.7 Data# Polling Algorithm**8.8.2 DQ6: Toggle Bit I**

Toggle Bit I on DQ6 indicates whether an Embedded Program or Erase algorithm is in progress or complete, or whether the device has entered the Erase Suspend mode.

Toggle Bit I may be read at any address in the same bank, and is valid after the rising edge of the final WE# pulse in the command sequence (prior to the program or erase operation), and during the sector erase time-out.

During an Embedded Program or Erase algorithm operation, two immediate consecutive read cycles to any address cause DQ6 to toggle. When the operation is complete, DQ6 stops toggling. For asynchronous mode, either OE# or CE# can be used to control the read cycles. For synchronous mode, the rising edge of ADV# is used or the rising edge of clock while ADV# is Low.

After an erase command sequence is written, if all sectors selected for erasing are protected, DQ6 toggles for approximately 100 μ s, then returns to reading array data. If not all selected sectors are protected, the Embedded Erase algorithm erases the unprotected sectors, and ignores the selected sectors that are protected.

The system can use DQ6 and DQ2 together to determine whether a sector is actively erasing or is erase-suspended. When the device is actively erasing (that is, the Embedded Erase algorithm is in progress), DQ6 toggles. When the device enters the Erase Suspend mode, DQ6 stops toggling. However, the system must also use DQ2 to determine which sectors are erasing or erase-suspended. Alternatively, the system can use DQ7 (see the subsection on DQ7: Data# Polling).

If a program address falls within a protected sector, DQ6 toggles for approximately 1 μ s after the program command sequence is written, then returns to reading array data.

DQ6 also toggles during the erase-suspend-program mode, and stops toggling once the Embedded Program Algorithm is complete.

See [Figure 18.12, Toggle Bit Timings \(During Embedded Algorithms\)](#), on page 64 for additional information.

8.8.3 DQ2: Toggle Bit II

The “Toggle Bit II” on DQ2, when used with DQ6, indicates whether a particular sector is actively erasing (that is, the Embedded Erase algorithm is in progress), or whether that sector is erase-suspended. Toggle Bit II is valid after the rising edge of the final WE# pulse in the command sequence. DQ2 toggles when the system performs two consecutive reads at addresses within those sectors that have been selected for erasure. But DQ2 cannot distinguish whether the sector is actively erasing or is erase-suspended. DQ6, by comparison, indicates whether the device is actively erasing, or is in Erase Suspend, but cannot distinguish which sectors are selected for erasure. Thus, both status bits are required for sector and mode information. Refer to [Table 8.8](#) to compare outputs for DQ2 and DQ6. See [DQ6: Toggle Bit I on page 35](#) for additional information.

8.8.4 Reading Toggle Bits DQ6/DQ2

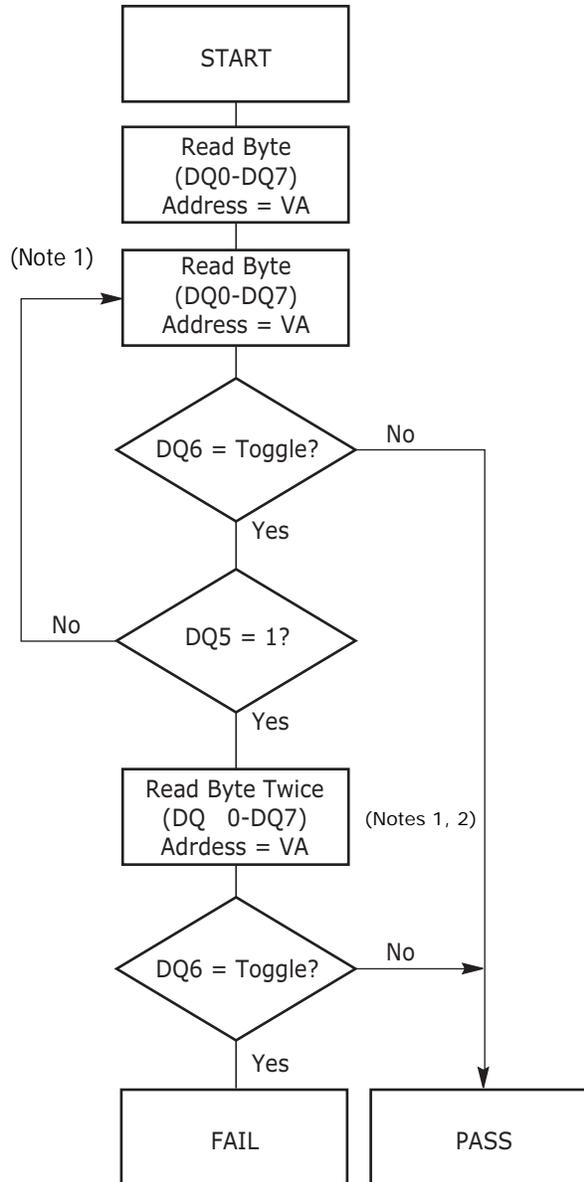

Whenever the system initially begins reading toggle bit status, it must perform two consecutive reads of DQ7-DQ0 in a row in order to determine whether a toggle bit is toggling. Typically, the system notes and stores the value of the toggle bit after the first read. After the second read, the system compares the new value of the toggle bit with the first. If the toggle bit is not toggling, the device completes the program or erases operation. The system can read array data on DQ7-DQ0 on the following read cycle.

However, if after the initial two read cycles, the system determines that the toggle bit is still toggling, the system also notes whether the value of DQ5 is high (see the section on DQ5). If it is, the system then determines again whether the toggle bit is toggling, since the toggle bit may have stopped toggling just as DQ5 went high. If the toggle bit is no longer toggling, the device has successfully completed the program or erases operation. If it is still toggling, the device had not completed the operation successfully, and the system writes the reset command to return to reading array data.

The remaining scenario is that the system initially determines that the toggle bit is toggling and DQ5 has not gone high. The system may continue to monitor the toggle bit and DQ5 through successive read cycles, determining the status as described in the previous paragraph. Alternatively, the system may choose to perform other system tasks. In this case, the system must start at the beginning of the algorithm when it returns to determine the status of the operation. Refer to [Figure 8.8](#) for more on the Toggle Bit Algorithm.

Table 8.8 DQ6 and DQ2 Indications

| If device is | and the system reads | then DQ6 | and DQ2 |
|-------------------------------|--|---------------------|---|
| programming, | at any address, | toggles, | does not toggle. |
| actively erasing, | at an address within a sector selected for erasure, | toggles, | also toggles. |
| | at an address within sectors not selected for erasure, | toggles, | does not toggle |
| erase suspended, | at an address within sectors selected for erasure, | does not toggle, | toggles. |
| | at an address within sectors not selected for erasure, | returns array data, | returns array data. The system can read from any sector not selected for erasure. |
| programming in erase suspend, | at any address, | toggles, | is not applicable. |

Notes:

1. Read toggle bit with two immediately consecutive reads to determine whether or not it is toggling.
2. Recheck toggle bit because it may stop toggling as DQ5 changes to 1.

Figure 8.8 Toggle Bit Algorithm

8.8.5 DQ5: Exceeded Timing Limits

DQ5 indicates whether the program or erase time has exceeded a specified internal pulse count limit. Under these conditions DQ5 produces a 1. This is a failure condition that indicates the program or erase cycle was not successfully completed.

The DQ5 failure condition may appear if the system tries to program a 1 to a location that is previously programmed to 0. Only an erase operation can change a 0 back to a 1. Under this condition, the device halts the operation, and when the operation has exceeded the timing limits, DQ5 produces a 1.

Under both these conditions, the system issues the reset command to return the device to reading array data.

8.8.6 DQ3: Sector Erase Timer

After writing a sector erase command sequence, the system may read DQ3 to determine whether or not erasure has begun. (The sector erase timer does not apply to the chip erase command.) If additional sectors are selected for erasure, the entire time-out also applies after each additional sector erase command. When the time-out period is complete, DQ3 switches from a "0" to a "1." If the time between additional sector erase commands from the system can be assumed to be less than 50 μ s, the system need not monitor DQ3. See *Sector Erase* on page 30 for more details.

After the sector erase command is written, the system reads the status of DQ7 (Data# Polling) or DQ6 (Toggle Bit I) to ensure that the device has accepted the command sequence, then reads DQ3. If DQ3 is "1," the Embedded Erase algorithm has begun; all further commands (except Erase Suspend) are ignored until the erase operation is complete. If DQ3 is "0," the device accepts additional sector erase commands.

To ensure the command has been accepted, the system software check the status of DQ3 prior to and following each sub-sequent sector erase command. If DQ3 is high on the second status check, the last command might not have been accepted. Table 8.9 shows the status of DQ3 relative to the other status bits.

8.8.7 RY/BY#: Ready/Busy#

The device provides a RY/BY# open drain output pin as a way to indicate to the host system that the Embedded Algorithms are either in progress or have been completed. If the output of RY/BY# is low, the device is busy with either a program, erase, or reset operation. If the output is floating, the device is ready to accept any read/write or erase operation. When the RY/BY# pin is low, the device will not accept any additional program or erase commands with the exception of the Erase suspend command. If the device has entered Erase Suspend mode, the RY/BY# output is floating. For programming, the RY/BY# is valid (RY/BY# = 0) after the rising edge of the fourth WE# pulse in the four write pulse sequence. For chip erase, the RY/BY# is valid after the rising edge of the sixth WE# pulse in the six write pulse sequence. For sector erase, the RY/BY# is also valid after the rising edge of the sixth WE# pulse.

If RESET# is asserted during a program or erase operation, the RY/BY# pin remains a 0 (busy) until the internal reset operation is complete, which requires a time of t_{READY} (during Embedded Algorithms). The system can thus monitor RY/BY# to determine whether the reset operation is complete. If RESET# is asserted when a program or erase operation is not executing (RY/BY# pin is floating), the reset operation is completed in a time of t_{READY} (not during Embedded Algorithms). The system can read data t_{RH} after the RESET# pin returns to V_{IH} .

Since the RY/BY# pin is an open-drain output, several RY/BY# pins can be tied together in parallel with a pull-up resistor to V_{CC} . An external pull-up resistor is required to take RY/BY# to a V_{IH} level since the output is an open drain.

Table 8.9 shows the outputs for RY/BY#, DQ7, DQ6, DQ5, DQ3 and DQ2. Figure 18.2, Figure 18.6, Figure 18.8 and Figure 18.9 show RY/BY# for read, reset, program, and erase operations, respectively.

Table 8.9 Write Operation Status

| Operation | | DQ7 (Note 2) | DQ6 | DQ5 (Note 1) | DQ3 | DQ2 (Note 2) | RY/BY# |
|--------------------|---|-----------------|-----------|-----------------|------|-----------------|--------|
| Standard Mode | Embedded Program Algorithm | DQ7# | Toggle | 0 | N/A | No toggle | 0 |
| | Embedded Erase Algorithm | 0 | Toggle | 0 | 1 | Toggle | 0 |
| Erase Suspend Mode | Reading within Erase Suspended Sector | 1 | No toggle | 0 | N/A | Toggle | 1 |
| | Reading within Non-Erase Suspended Sector | Data | Data | Data | Data | Data | 1 |
| | Erase-Suspend-Program | DQ7# | Toggle | 0 | N/A | N/A | 0 |

Notes:

1. DQ5 switches to 1 when an Embedded Program or Embedded Erase operation has exceeded the maximum timing limits. See DQ5: Exceeded Timing Limits on page 38 for more information.
2. DQ7 and DQ2 require a valid address when reading status information. See DQ7: Data# Polling on page 34 and DQ2: Toggle Bit II on page 36 for further details.

8.9 Reset Command

Writing the reset command resets the device to the read or erase-suspend-read mode. Address bits are don't cares for this command.

The reset command may be written between the cycles in an erase command sequence before erasing begins. This resets the device to the read mode. However, once erasure begins, the device ignores the reset commands until the operation is complete.

The reset command may be written between the cycles in a program command sequence before programming begins. This resets the device to the read mode. If the program command sequence is written while the device is in the Erase Suspend mode, writing the reset command returns the device to the erase-suspend-read mode. However, once programming begins, the device ignores the reset commands until the operation is complete.

The reset command may be written between the cycles in an autoselect command sequence. Once in the autoselect mode, the reset command must be written to exit the autoselect mode and return to the read mode.

If DQ5 goes high during a program or erase operation, writing the reset command returns the device to the read mode or erase-suspend-read-mode if the device was in Erase Suspend. When the reset command is written, before the embedded operation starts, the device requires t_{RR} before it returns to the read or erase-suspend-read mode.

Table 8.10 Reset Command Timing

| Parameter | Description | Max. | Unit |
|-----------|---|------|------|
| t_{RR} | Reset Command to Read Mode or Erase-Suspend-Read Mode | 250 | ns |

9 Advanced Sector Protection/Unprotection

The Advanced Sector Protection/Unprotection feature disables or enables programming or erase operations in any or all sectors and can be implemented through software and/or hardware methods, which are independent of each other. This section describes the various methods of protecting data stored in the memory array. An overview of these methods is shown in Figure 9.1.

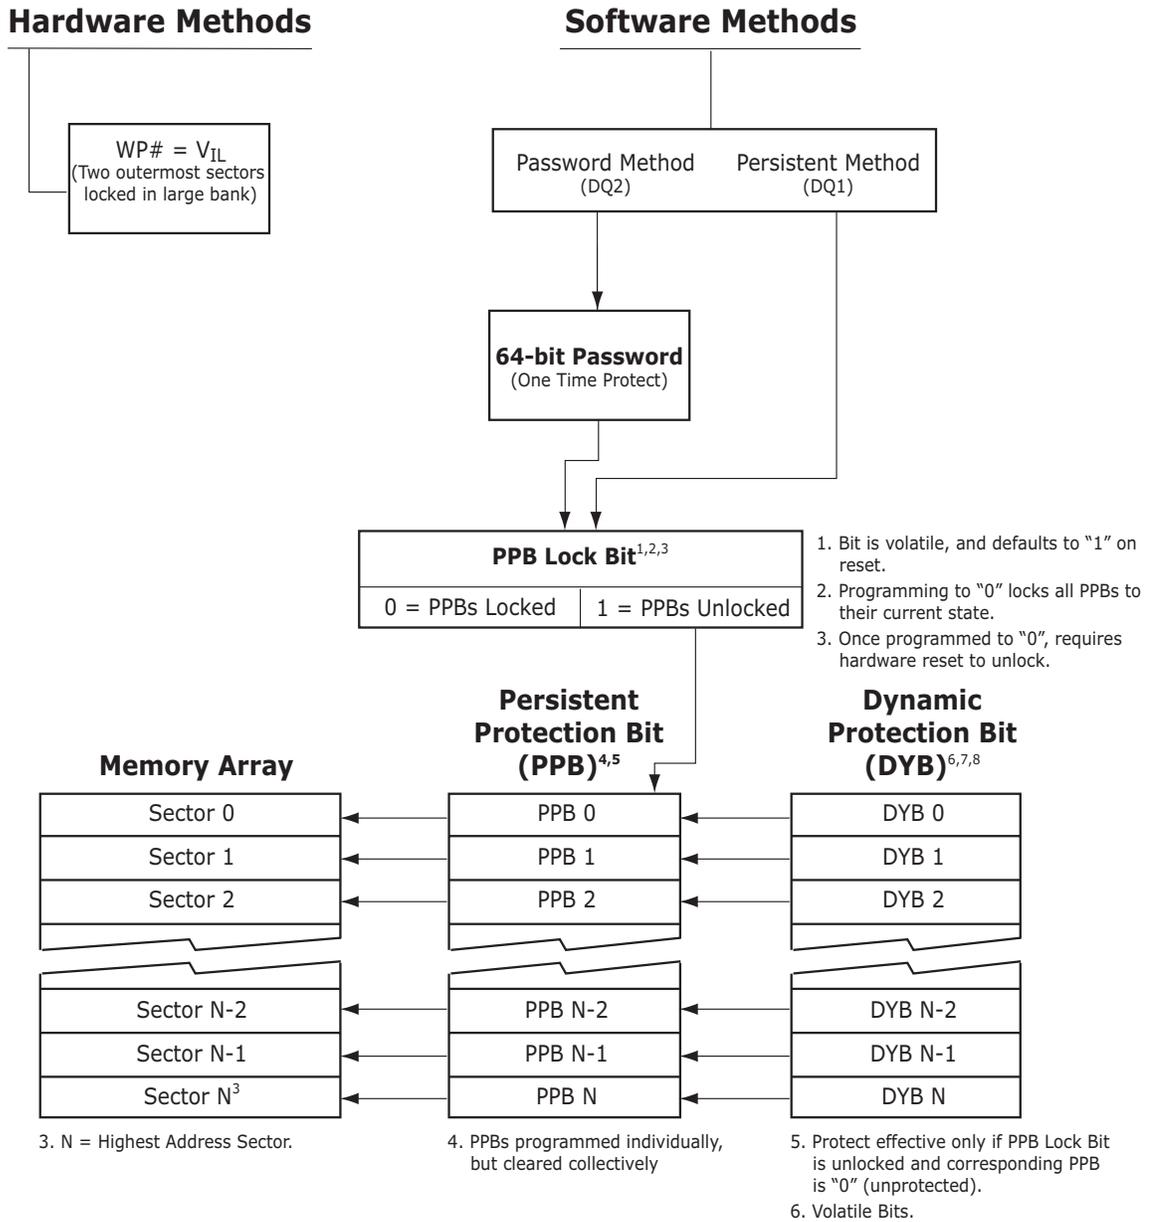

Figure 9.1 Advanced Sector Protection/Unprotection

9.1 Advanced Sector Protection Overview

As shipped from the factory, all devices default to the persistent mode when power is applied, and all sectors are unprotected. The device programmer or host system must then choose which sector protection method to use. Programming (setting to "0") any one of the following two one-time programmable, non-volatile bits locks the device permanently in that mode:

- Persistent Protection Mode Lock Bit
- Password Protection Mode Lock Bit

After selecting a sector protection method, each sector can operate in any of the following three states:

1. Persistently Locked. A sector is protected and cannot be changed.
2. Dynamically locked. The selected sectors are protected and can be altered via software commands.
3. Unlocked. The sectors are unprotected and can be erased and/or programmed.

These states are controlled by the bit types described between page 42 and page 45.

Notes:

1. If the password mode is chosen, the password must be programmed before setting the corresponding lock register bit. The user must be sure that the password is correct when the Password Mode Locking Bit is set, as there is no means to verify the password afterwards.
2. If both lock bits are selected to be programmed (to zeros) at the same time, the operation aborts.
3. Once the Password Mode Lock Bit is programmed, the Persistent Mode Lock Bit is permanently disabled, and no changes to the protection scheme are allowed. Similarly, if the Persistent Mode Lock Bit is programmed, the Password Mode is permanently disabled.
4. It is important that the mode is explicitly selected when the device is first programmed, rather than relying on the default mode alone. This is so that it is impossible for a system program or virus to later set the Password Mode Locking Bit, which would cause an unexpected shift from the default Persistent Sector Protection Mode into the Password Protection Mode.
5. If the user attempts to program or erase a protected sector, the device ignores the command and returns to read mode. A program command to a protected sector enables status polling for approximately 1 μ s before the device returns to read mode without modifying the contents of the protected sector. An erase command to a protected sector enables status polling for approximately 50 μ s, after which the device returns to read mode without having erased the protected sector.
6. For the command sequence required for programming the lock register bits, refer to *Command Definitions on page 71*.

9.2 Persistent Protection Bits

The Persistent Protection Bits are unique and nonvolatile. A single Persistent Protection Bit is assigned to a maximum for four sectors (see the sector address tables for specific sector protection groupings). All eight-Kbyte boot-block sectors have individual sector Persistent Protection Bits (PPBs) for greater flexibility.

Notes:

1. Each PPB is individually programmed and all are erased in parallel. There are no means for individually erasing a specific PPB and no specific sector address is required for this operation.
2. If a PPB requires erasure, all of the sector PPBs must first be programmed prior to PPB erasing. It is the responsibility of the user to perform the preprogramming operation. Otherwise, an already erased sector PPB has the potential of being over-erased. There is no hardware mechanism to prevent sector PPB over-erasure.

- If the PPB Lock Bit is set, the PPB Program or erase command does not execute and times-out without programming or erasing the PPB.

9.2.1 Programming PPB

The PPB Program Command is used to program, or set, a given PPB. The first three cycles in the PPB Program Command are standard unlock cycles. The fourth cycle in the PPB Program Command executes the pulse which programs the specified PPB. The user must wait either 100 μ s or until DQ6 stops toggling before executing the fifth cycle, which is the read verify portion of the PPB Program Command. The sixth cycle outputs the status of the PPB Program operation.

In the event that the program PPB operation was not successful, the user can loop directly to the fourth cycle of the PPB Program Command to perform the program pulse and read verification again. After four unsuccessful loops through the program pulse and read verification cycles the PPB programming operation should be considered a failure.

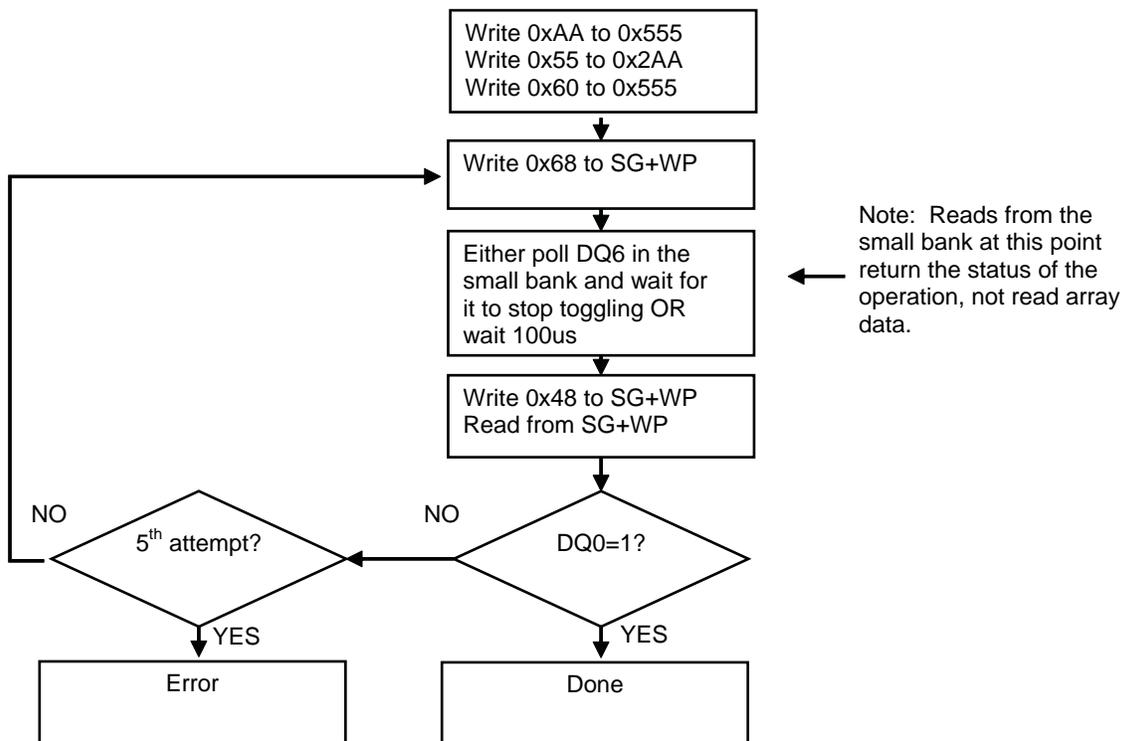

Figure 9.2 PPB Program Operation

9.2.2 Erasing PPB

The All PPB Erase command is used to erase all the PPBs in bulk. There are no means for individually erasing a specific PPB. The first three cycles of the PPB Erase command are standard unlock cycles. The fourth cycle executes the erase pulse to all the PPBs. The user must wait either 20ms or until DQ6 stops toggling before executing the fifth cycle, which is the read verify portion of the PPB Erase Command. The sixth cycle outputs the status of the PPB Erase operation.

In the event that the erase PPB operation was not successful, the user can loop directly to the fourth cycle of the All PPB Erase Command to perform the erase pulse and read verification again. After four unsuccessful loops through the erase pulse and read verification cycles, the PPB erasing operation should be considered a failure.

Note:

- All PPB must be preprogrammed prior to issuing the All PPB Erase Command.

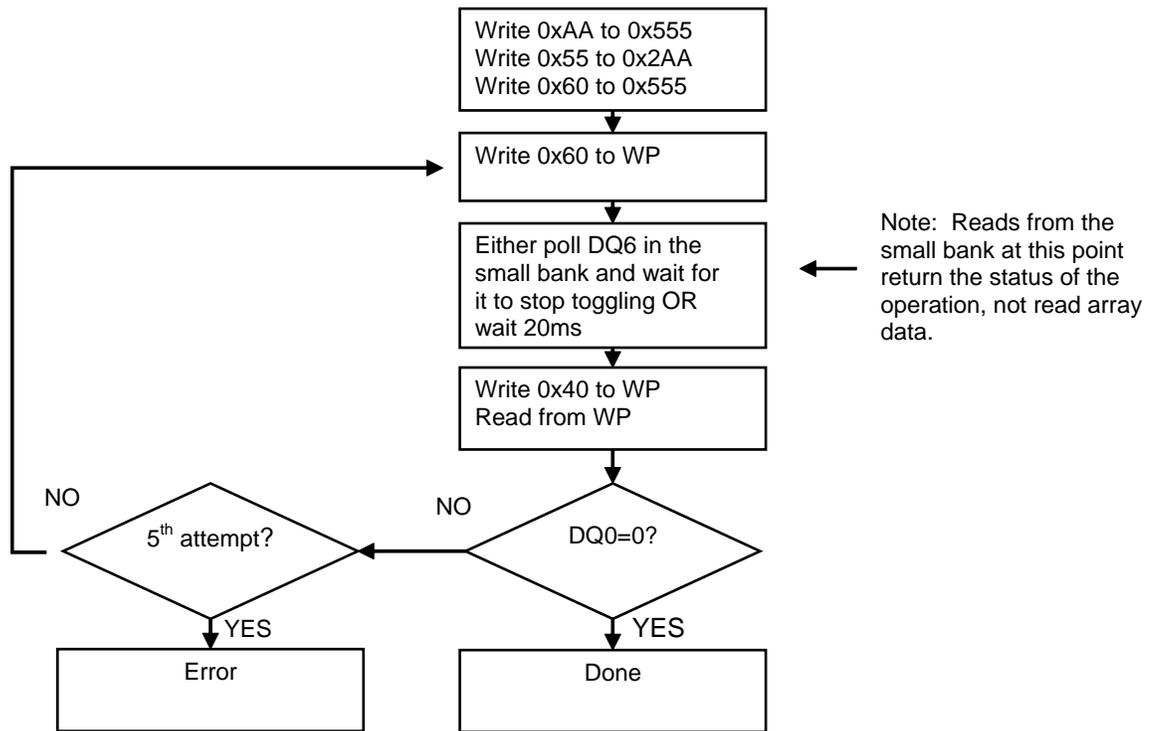

Figure 9.3 PPB Erase Operation

9.3 Persistent Protection Bit Lock Bit

The Persistent Protection Bit Lock Bit is a global volatile bit for all sectors. When set to "1", it locks all PPBs; when set to "0", it allows the PPBs to be changed. There is only one PPB Lock Bit per device.

Notes:

1. No software command sequence unlocks this bit unless the device is in the password protection mode; only a hardware reset or a power-up clears this bit.
2. The PPB Lock Bit must be set only after all PPBs are configured to the desired settings.

9.4 Dynamic Protection Bits

A Dynamic Protection Bit (DYB) is volatile and unique for each sector and can be individually modified. DYBs only control the protection scheme for unprotected sectors that have their PPBs set to "0". By issuing the DYB Set or Clear command sequences, the DYBs are set or cleared, thus placing each sector in the protected or unprotected state respectively. This feature allows software to easily protect sectors against inadvertent changes, yet does not prevent the easy removal of protection when changes are needed.

Notes:

1. The DYBs can be set or cleared as often as needed with the DYB Write Command.
2. When the parts are first shipped, the PPBs are cleared, the DYBs are cleared, and PPB Lock is defaulted to power up in the cleared state – meaning the PPBs are changeable. The DYB are also always cleared after a power-up or reset.
3. It is possible to have sectors that are persistently locked with sectors that are left in the dynamic state.

- The DYB Set or Clear commands for the dynamic sectors signify the protected or unprotected state of the sectors respectively. However, if there is a need to change the status of the persistently locked sectors, a few more steps are required. First, the PPB Lock Bit must be cleared by either putting the device through a power-cycle, or hardware reset. The PPBs can then be changed to reflect the desired settings. Setting the PPB Lock Bit once again locks the PPBs, and the device operates normally again.

Table 9.1 Sector Protection Schemes

| DYB | PPB | PPB Lock | Sector State |
|-----|-----|----------|---|
| 0 | 0 | 0 | Unprotected—PPB and DYB are changeable |
| 0 | 0 | 1 | Unprotected—PPB not changeable, DYB is changeable |
| 0 | 1 | 0 | Protected—PPB and DYB are changeable |
| 1 | 0 | 0 | |
| 1 | 1 | 0 | |
| 0 | 1 | 1 | Protected—PPB not changeable, DYB is changeable |
| 1 | 0 | 1 | |
| 1 | 1 | 1 | |

9.5 Password Protection Method

The Password Protection Method allows an even higher level of security than the Persistent Sector Protection Mode by requiring a 64-bit password for unlocking the device PPB Lock Bit. In addition to this password requirement, after power-up and reset, the PPB Lock Bit is set "1" in order to maintain the password mode of operation. Successful execution of the Password Unlock command by entering the entire password clears the PPB Lock Bit, allowing for sector PPBs modifications.

Notes:

- There is no special addressing order required for programming the password. Once the password is written and verified, the Password Mode Locking Bit must be set in order to prevent access.
- The Password Program Command is only capable of programming "0"s. Programming a "1" after a cell is programmed as a "0" results in a time-out with the cell as a "0". (This is an OTP area).
- The password is all "1"s when shipped from the factory.
- When the password is undergoing programming, Simultaneous Read/Write operation is disabled. Read operations to any memory location returns the programming status. Once programming is complete, the user must issue a Read/Reset command to return the device to normal operation.
- All 64-bit password combinations are valid as a password.
- There is no means to read, program or erase the password is after it is set.
- The Password Mode Lock Bit, once set, prevents reading the 64-bit password on the data bus and further password programming.
- The Password Mode Lock Bit is not erasable.
- The exact password must be entered in order for the unlocking function to occur.
- There is a built-in 2- μ s delay for each password check. This delay is intended to stop any efforts to run a program that tries all possible combinations in order to crack the password.

9.6 Hardware Data Protection Methods

The device offers several methods of data protection by which intended or accidental erasure of any sectors can be prevented via hardware means. The following subsections describe these methods.

9.6.1 WP# Method

The Write Protect feature provides a hardware method of protecting the two outermost sectors of the large bank.

If the system asserts V_{IL} on the WP# pin, the device disables program and erase functions in the two "outermost" boot sectors (8-Kbyte sectors) in the large bank. If the system asserts V_{IH} on the WP# pin, the device reverts to whether the boot sectors were last set to be protected or unprotected. That is, sector protection or unprotection for these sectors depends on whether they were last protected or unprotected.

Note that the WP# pin must not be left floating or unconnected as inconsistent behavior of the device may result.

The WP# pin must be held stable during a command sequence execution

9.6.2 Low V_{CC} Write Inhibit

When V_{CC} is less than V_{LKO} , the device does not accept any write cycles. This protects data during V_{CC} power-up and power-down.

The command register and all internal program/erase circuits are disabled, and the device resets to reading array data. Subsequent writes are ignored until V_{CC} is greater than V_{LKO} . The system must provide the proper signals to the control inputs to prevent unintentional writes when V_{CC} is greater than V_{LKO} .

9.6.3 Write Pulse "Glitch Protection"

Noise pulses of less than 5 ns (typical) on OE#, CE# or WE# do not initiate a write cycle.

9.6.4 Power-Up Write Inhibit

If $WE\# = CE\# = RESET\# = V_{IL}$ and $OE\# = V_{IH}$ during power-up, the device does not accept commands on the rising edge of WE#. The internal state machine is automatically reset to the read mode on power-up.

9.6.5 V_{CC} and V_{IO} Power-up And Power-down Sequencing

The device imposes no restrictions on V_{CC} and V_{IO} power-up or power-down sequencing. Asserting $RESET\#$ to V_{IL} is required during the entire V_{CC} and V_{IO} power sequence until the respective supplies reach the operating voltages. Once, V_{CC} and V_{IO} attain the operating voltages, deassertion of $RESET\#$ to V_{IH} is permitted.

9.6.6 Logical Inhibit

Write cycles are inhibited by holding any one of $OE\# = V_{IL}$, $CE\# = V_{IH}$, or $WE\# = V_{IH}$. To initiate a write cycle, CE# and WE# must be a logical zero (VIL) while OE# is a logical one (VIH).

10 Secured Silicon Sector Flash Memory Region

The Secured Silicon Sector provides an extra Flash memory region that enables permanent part identification through an Electronic Serial Number (ESN). The Secured Silicon Sector is a 256-byte flash memory area that is either programmable at the customer, or by Spansion at the request of the customer. See [Table 10.1](#) for the Secured Silicon Sector address ranges.

All Secured Silicon reads outside of the 256-byte address range return invalid data.

Table 10.1 Secured Silicon Sector Addresses

| Ordering Option | Sector Size (Bytes) | Address Range |
|-----------------|---------------------|--|
| Top Boot | 256 | 00000h-0003Fh (16 Mb & 32 Mb) |
| Bottom Boot | 256 | FFFC0h-FFFFFh (32 Mb) 7FFC0h-7FFFFh (16 Mb) |

The device allows Simultaneous Read/Write operation while the Secured Silicon Sector is enabled. However, several restrictions are associated with Simultaneous Read/Write operation and device operation when the Secured Silicon Sector is enabled:

1. The Secured Silicon Sector is not available for reading while the Password Unlock, any PPB program/erase operation, or Password programming are in progress. Reading to any location in the small bank will return the status of these operations until these operations have completed execution.
2. Programming the DYB associated with the overlaid boot-block sector results in the DYB NOT being updated. This occurs only when the Secured Silicon sector is not enabled.
3. Reading the DYB associated with the overlaid boot-block sector when the PPB Lock/DYB Verify command is issued, causes the read command to return invalid data. This function occurs only when the Secured Silicon Sector is not enabled.
4. All commands are available for execution when the Secured Silicon Sector is enabled, except the following:
 - Any Unlock Bypass command
 - CFI
 - Accelerated Program
 - Program and Sector Erase Suspend
 - Program and Sector Erase Resume

Issuing the above commands while the Secured Silicon Sector is enabled results in the command being ignored.

5. It is valid to execute the Sector Erase command on any sector other than the Secured Silicon Sector when the Secured Silicon Sector is enabled. However, it is not possible to erase the Secured Silicon Sector using the Sector Erase Command, as it is a one-time programmable (OTP) area that can not be erased.
6. Executing the Chip Erase command is permitted when the Secured Silicon Sector is enabled. The Chip Erase command erases all sectors in the memory array, except for sector 0 in top-boot block configuration, or sector 45 in bottom-boot block configuration. The Secured Silicon Sector is a one-time programmable memory area that cannot be erased.
7. Executing the Secured Silicon Sector Entry command during program or erase suspend mode is allowed. The Sector Erase/Program Resume command is disabled when the Secured Silicon sector is enabled; the user cannot resume programming of the memory array until the Exit Secured Silicon Sector command is written.
8. Address range 00040h-007FFh for the top bootblock, and FF00h-FFF7Fh return invalid data when addressed with the Secured Silicon sector enabled.

9. The Secured Silicon Sector Entry command is allowed when the device is in either program or erase suspend modes. If the Secured Silicon sector is enabled, the program or erase suspend command is ignored. This prevents resuming either programming or erasure on the Secured Silicon sector if the overlaid sector was undergoing programming or erasure. The host system must ensure that the device resume any suspended program or erase operation after exiting the Secured Silicon sector.

10.1 Secured Silicon Sector Protection Bit

The Secured Silicon Sector can be shipped unprotected, allowing customers to utilize that sector in any manner they choose.

Please note the following:

- The Secured Silicon Sector can be read any number of times, but can be programmed and locked only once. The Secured Silicon Sector Protection Bit must be used with caution as once locked, there is no procedure available for unlocking the Secured Silicon Sector area and none of the bits in the Secured Silicon Sector memory space can be modified in any way.
- Once the Secured Silicon Sector is locked and verified, the system must write the Exit Secured Silicon Sector Region command sequence to return the device to the memory array.

10.2 Secured Silicon Sector Entry and Exit Commands

The system can access the Secured Silicon Sector region by issuing the three-cycle Enter Secured Silicon Sector command sequence. The device continues to access the Secured Silicon Sector region until the system issues the four-cycle Exit Secured Silicon Sector command sequence. See the [Table 20.1, Memory Array Command Definitions \(x32 Mode\), on page 71](#) and [Table 20.2, Sector Protection Command Definitions \(x32 Mode\), on page 72](#) for address and data requirements for both command sequences.

The Secured Silicon Sector Entry Command allows the following commands to be executed

- Read Secured Silicon areas
- Program Secured Silicon Sector (only once)

After the system has written the Enter Secured Silicon Sector command sequence, it can read the Secured Silicon Sector by using the addresses listed in [Table 10.1, Secured Silicon Sector Addresses on page 47](#). This mode of operation continues until the system issues the Exit Secured Silicon Sector command sequence, or until power is removed from the device.

II Electronic Marking

Electronic marking has been programmed into the device, prior to shipment from Spansion, to ensure traceability of individual products. The electronic marking is stored and locked within a one-time programmable region. Detailed information on Electronic Marking will be provided in a datasheet supplement.

12 Power Conservation Modes

12.1 Standby Mode

When the system is not reading or writing to the device, it can place the device in standby mode. In this mode, current consumption is greatly reduced, and outputs are placed in a high impedance state, independent of OE# input. The device enters CMOS standby mode when the CE# and RESET# inputs are both held at $V_{CC} \pm 0.2$ V. The device requires standard access time (t_{CE}) for read access before it is ready to read data. If the device is deselected during erasure or programming, the device draws active current until the operation is completed.

I_{CC5} in *CMOS Compatible* on page 52 represents the standby current specification.

Caution: Entering standby mode via the RESET# pin also resets the device to read mode and floats the data I/O pins. Furthermore, entering ICC7 during a program or erase operation leaves erroneous data in the address locations being operated on at the time of the RESET# pulse. These locations require updating after the device resumes standard operations. See *Hardware RESET# Input Operation* for further discussion of the RESET# pin and its functions.

12.2 Automatic Sleep Mode

The automatic sleep mode minimizes Flash device energy consumption. The automatic sleep mode is independent of the CE#, WE# and OE# control signals. While in sleep mode, output data is latched and always available to the system.

While in asynchronous mode, the device automatically enables this mode when addresses remain stable for $t_{ACC} + 60$ ns. Standard address access timings provide new data when addresses are changed. While in synchronous mode, the device automatically enables this mode when either the first active CLK level is greater than t_{ACC} or the CLK runs slower than 5 MHz. A new burst operation is required to provide new data.

I_{CC8} in *CMOS Compatible* on page 52 represents the automatic sleep mode current specification.

12.3 Hardware RESET# Input Operation

The RESET# input provides a hardware method of resetting the device to reading array data. When RESET# is driven low, the device immediately terminates any operation in progress, tristates all outputs, resets the configuration register, and ignores all read/write commands for the duration of the RESET# pulse. The device also resets the internal state machine to reading array data. Any operation that was interrupted should be reinitiated once the device is ready to accept another command sequence, in order to ensure data integrity.

When RESET# is held at $V_{SS} \pm 0.2$ V, the device draws CMOS standby current (ICC4). If RESET# is held at V_{IL} but not within $V_{SS} \pm 0.2$ V, the standby current is greater.

RESET# may be tied to the system reset circuitry, thus a system reset would also reset the Flash memory, enabling the system to read the boot-up firmware from the Flash memory.

If RESET# is asserted during a program or erase operation, the RY/BY# pin remains low until the reset operation is internally complete. This action requires between 1 μ s and 7 μ s for either Chip Erase or Sector Erase. The RY/BY# pin can be used to determine whether the reset operation is complete. Otherwise, allow for the maximum reset time of 11 μ s.

If RESET# is asserted when a program or erase operation is not executing (RY/BY# = 1), the reset operation completes within 500 ns. The Simultaneous Read/Write feature of this device allows the user to read a bank after 500 ns if the bank is in the read/reset mode at the time RESET# is asserted. If one of the banks is in the middle of either a program or erase operation when RESET# is asserted, the user must wait 11 μ s before accessing that bank.

Asserting RESET# active during Vcc and VIO power up is required to guarantee proper device initialization until VCC and VIO have reached steady state voltages.

12.4 Output Disable (OE#)

When the OE# input is at V_{IH} , output from the device is disabled. The outputs are placed in the high impedance state.

13 Electrical Specifications

13.1 Absolute Maximum Ratings

| | |
|--|------------------------|
| Storage Temperature, Plastic Packages | -65°C to +150°C |
| Ambient Temperature with Power Applied | -65°C to +145°C |
| V_{CC} , V_{IO} (Note 1) for 2.6 V devices (S29CD-J) | -0.5V to +3.6 V |
| V_{CC} , V_{IO} (Note 1) for 3.3 V devices (S29CL-J) | -0.5V to +3.6V |
| ACC, A9, and RESET# (Note 2) | -0.5 V to +13.0 V |
| Address, Data, Control Signals (with the exception of CLK) (Note 1) | -0.5 V to +3.6V (16Mb) |
| | -0.5V to +2.75V (32Mb) |
| All other pins (Note 1) | -0.5 V to +3.6V (16Mb) |
| | -0.5V to +2.75V (32Mb) |
| Output Short Circuit Current (Note 3) | 200 mA |

Notes:

1. Minimum DC voltage on input or I/O pins is -0.5 V. During voltage transitions, input at I/O pins may overshoot V_{SS} to -2.0 V for periods of up to 20 ns. See Figure 13.2. Maximum DC voltage on output and I/O pins is 3.6 V. During voltage transitions output pins may overshoot to $V_{CC} + 2.0$ V for periods up to 20 ns. See Figure 13.1.
2. Minimum DC input voltage on pins ACC, A9, and RESET# is -0.5 V. During voltage transitions, A9 and RESET# may overshoot V_{SS} to -2.0 V for periods of up to 20 ns. See Figure 13.1. Maximum DC input voltage on pin A9 is +13.0 V which may overshoot to 14.0 V for periods up to 20 ns.
3. No more than one output may be shorted to ground at a time. Duration of the short circuit should not be greater than one second.
4. Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational sections of this data sheet is not implied. Exposure of the device to absolute maximum rating conditions for extended periods may affect device reliability.

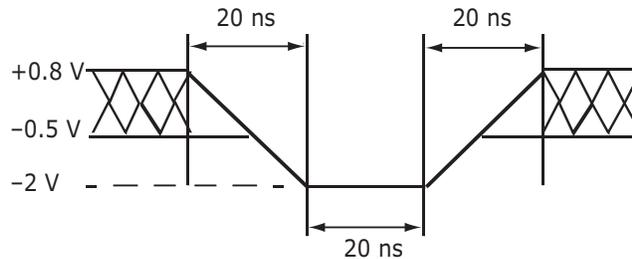

Figure 13.1 Maximum Negative Overshoot Waveform

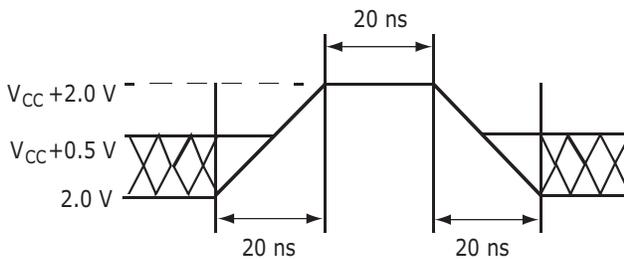

Figure 13.2 Maximum Positive Overshoot Waveform

I4 Operating Ranges

Industrial Devices

Ambient Temperature (T_A) -40°C to $+85^{\circ}\text{C}$

Extended Devices

Ambient Temperature (T_A) -40°C to $+125^{\circ}\text{C}$

V_{CC} Supply Voltages

V_{CC} for 2.6 V regulated voltage range (S29CD-J devices) 2.50 V to 2.75 V

V_{CC} for 3.3 V regulated voltage range (S29CL-J devices) 3.00 V to 3.60 V

V_{IO} Supply Voltages

V_{IO} (S29CD-J devices) 1.65V to 2.75V

V_{IO} (S29CL-J devices) 1.65V to 3.6V

Operating ranges define those limits between which the functionality of the device is guaranteed.

15 DC Characteristics

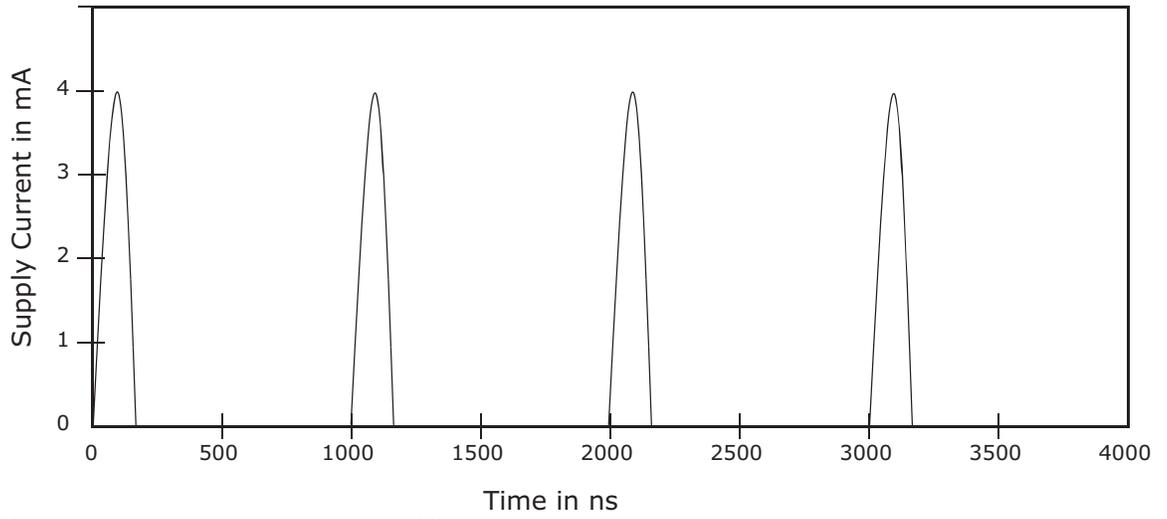

15.1 CMOS Compatible

| Parameter | Description | Test Conditions | Min | Typ | Max | Unit |
|-------------|--|--|----------------------|-----|---------------------|---------|
| I_{LI} | Input Load Current | $V_{IN} = V_{SS}$ to V_{IO} , $V_{IO} = V_{IO\ max}$ | | | ± 1.0 | μA |
| I_{LIWP} | WP# Input Load Current | $V_{IN} = V_{SS}$ to V_{IO} , $V_{IO} = V_{IO\ max}$ | | | -25 | μA |
| I_{LIT} | A9, ACC Input Load Current | $V_{CC} = V_{CC\ max}$; A9 = 12.5 V | | | 35 | μA |
| I_{LO} | Output Leakage Current | $V_{OUT} = V_{SS}$ to V_{CC} , $V_{CC} = V_{CC\ max}$ | | | ± 1.0 | μA |
| I_{CCB} | V_{CC} Active Burst Read Current (1) | CE# = V_{IL} , OE# = V_{IL} 56 MHz, 66, 75 MHz 8 Double Word | | 45 | 55 | mA |
| I_{CC1} | V_{CC} Active Asynchronous Read Current (1) | CE# = V_{IL} , OE# = V_{IL} 1 MHz | | | 4 | mA |
| I_{CC3} | V_{CC} Active Program Current (2, 3, 4) | CE# = V_{IL} , OE# = V_{IH} , ACC = V_{IH} | | 40 | 50 | mA |
| I_{CC4} | V_{CC} Active Erase Current (2, 3, 4) | CE# = V_{IL} , OE# = V_{IH} , ACC = V_{IH} | | 20 | 50 | mA |
| I_{CC5} | V_{CC} Standby Current (CMOS) | $V_{CC} = V_{CC\ max}$, CE# = $V_{CC} \pm 0.3\ V$ | | | 60 | μA |
| I_{CC6} | V_{CC} Active Current (Read While Write) (3) | CE# = V_{IL} , OE# = V_{IL} | | 30 | 90 | mA |
| I_{CC7} | V_{CC} Reset Current | RESET# = V_{IL} | | | 60 | μA |
| I_{CC8} | Automatic Sleep Mode Current | $V_{IH} = V_{CC} \pm 0.3\ V$, $V_{IL} = V_{SS} \pm 0.3\ V$ | | | 60 | μA |
| I_{ACC} | V_{ACC} Acceleration Current | ACC = V_{HH} | | | 20 | mA |
| V_{IL} | Input Low Voltage | | -0.5 | | $0.3 \times V_{IO}$ | V |
| V_{IH} | Input High Voltage | | $0.7 \times V_{IO}$ | | V_{CC} | V |
| V_{ILCLK} | CLK Input Low Voltage | | -0.2 | | $0.3 \times V_{IO}$ | V |
| V_{IHCLK} | CLK Input High Voltage | | $0.7 \times V_{CC}$ | | 2.75 | V |
| V_{ID} | Voltage for Autoselect | $V_{CC} = 2.5\ V$ | 11.5 | | 12.5 | V |
| V_{OL} | Output Low Voltage | $I_{OL} = 4.0\ mA$, $V_{CC} = V_{CC\ min}$ | | | 0.45 | V |
| I_{OLRB} | RY/BY#, Output Low Current | $V_{OL} = 0.4\ V$ | 8 | | | mA |
| V_{HH} | Accelerated (ACC pin) High Voltage | $I_{OH} = -2.0\ mA$, $V_{CC} = V_{CC\ min}$ | $0.85 \times V_{CC}$ | | | V |
| V_{OH} | Output High Voltage | $I_{OH} = -100\ \mu A$, $V_{CC} = V_{CC\ min}$ | $V_{IO} - 0.1$ | | | V |
| V_{LKO} | Low V_{CC} Lock-Out Voltage (3) | | 1.6 | | 2.0 | V |

Notes:

1. The I_{CC} current listed includes both the DC operating current and the frequency dependent component.
2. I_{CC} active while Embedded Erase or Embedded Program is in progress.
3. Not 100% tested.
4. Maximum I_{CC} specifications are tested with $V_{CC} = V_{CC\ max}$.

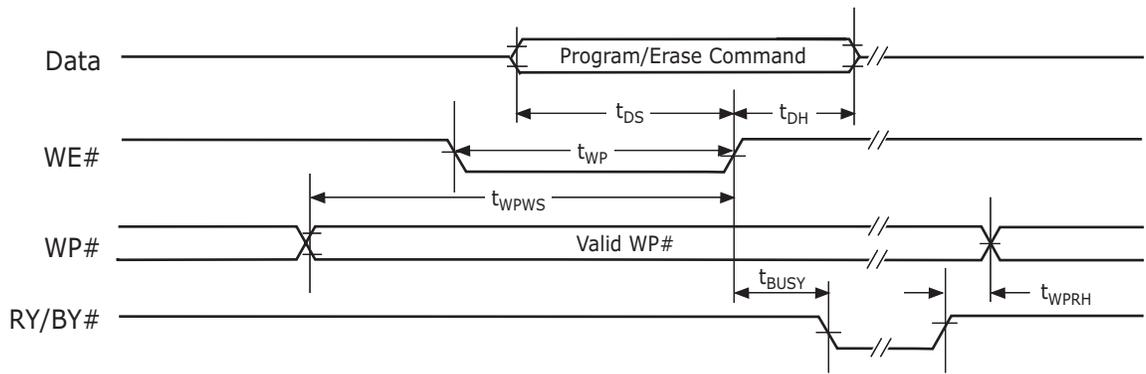

Figure 18.7 WP# Timing

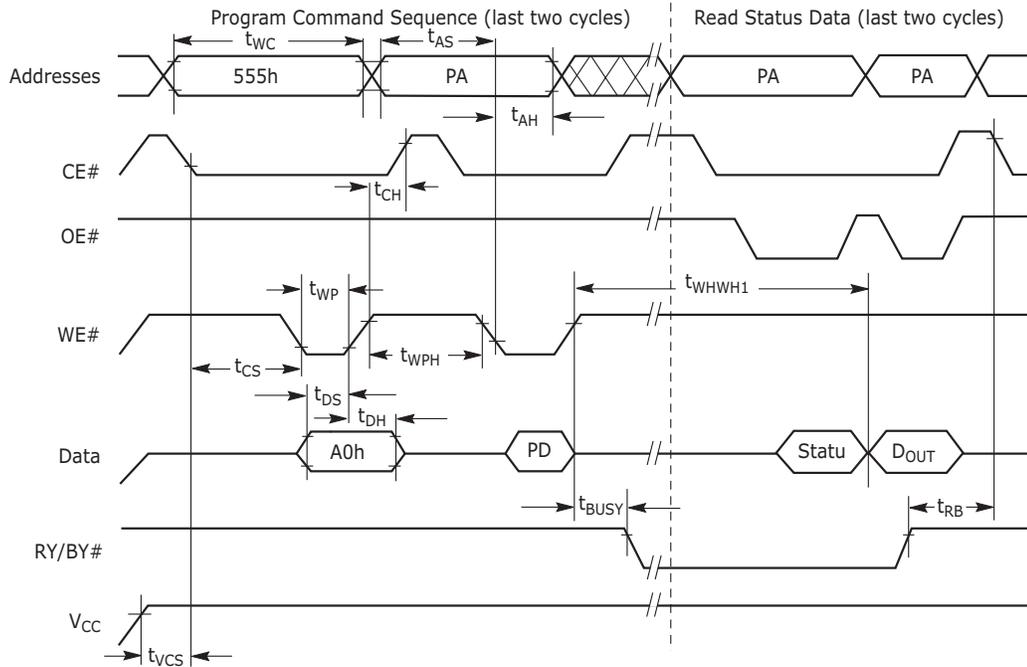

18.6 Erase/Program Operations

Table 18.5 Erase/Program Operations

| Parameter | | Description | | All Speed Options | | Unit |
|-------------|-------------|--|-------------|-------------------|-----|---------|
| JEDEC | Std. | | | Min | Max | |
| t_{AVAV} | t_{WC} | Write Cycle Time (Note 1) | Min | 60 | | ns |
| t_{AVWL} | t_{AS} | Address Setup Time | Min | 0 | | ns |
| t_{WLAX} | t_{AH} | Address Hold Time | Min | 25 | | ns |
| t_{DVWH} | t_{DS} | Data Setup to WE# Rising Edge | Min | 18 | | ns |
| t_{WHDX} | t_{DH} | Data Hold from WE# Rising Edge | Min | 2 | | ns |
| t_{GHWL} | t_{GHWL} | Read Recovery Time Before Write (OE# High to WE# Low) (Note 1) | Min | 0 | | ns |
| t_{ELWL} | t_{CS} | CE# Setup Time | Min | 0 | | ns |
| t_{WHEH} | t_{CH} | CE# Hold Time | Min | 0 | | ns |
| t_{WLWH} | t_{WP} | WE# Width | Min | 25 | | ns |
| t_{WHWL} | t_{WPH} | Write Pulse Width High | Min | 30 | | ns |
| t_{WHWH1} | t_{WHWH1} | Programming Operation (Note 2) | Double-Word | Typ | 9 | μ s |
| t_{WHWH2} | t_{WHWH2} | Sector Erase Operation (Note 2) | | Typ | 0.5 | sec. |
| | t_{VCS} | VCC Setup Time (Note 1) | Min | 50 | | μ s |
| | t_{RB} | Recovery Time from RY/BY# (Note 1) | Min | 0 | | ns |
| | t_{BUSY} | RY/BY# Delay After WE# Rising Edge (Note 1) | Max | 90 | | ns |
| | t_{WPWS} | WP# Setup to WE# Rising Edge with Command (Note 1) | Min | 20 | | ns |
| | t_{WPRH} | WP# Hold after RY/BY# Rising Edge (Note 1) | Max | 2 | | ns |

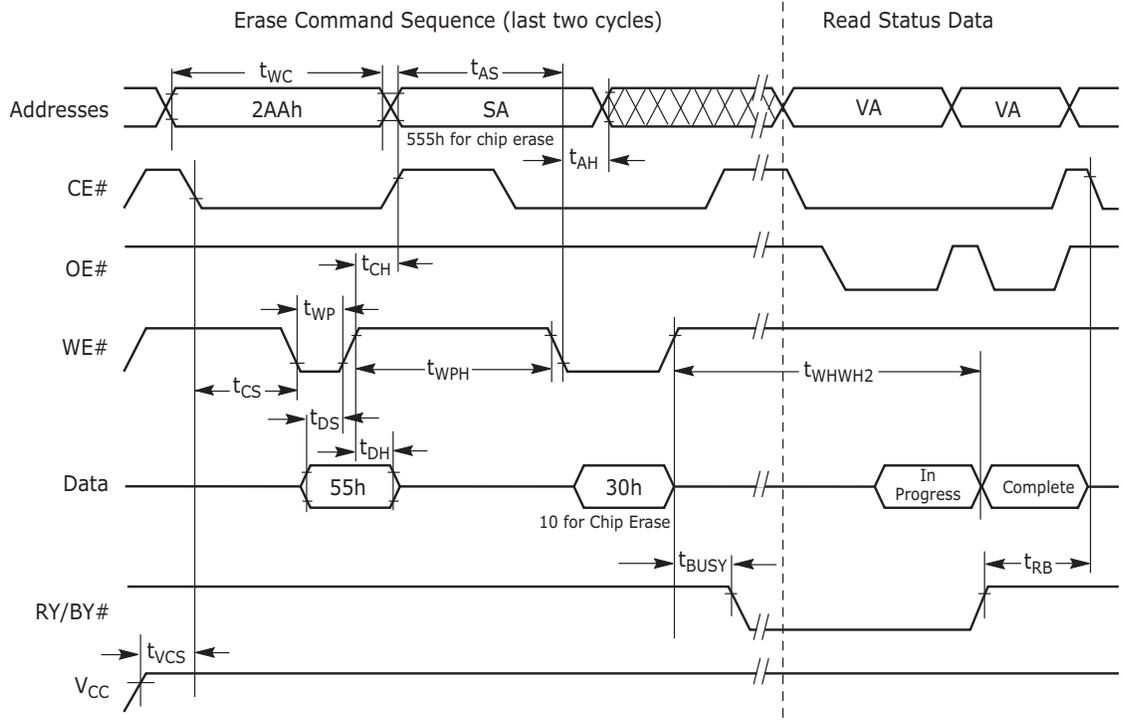

Notes:

1. Not 100% tested.
2. See Command Definitions on page 71 for more information.
3. Program Erase Parameters are the same, regardless of Synchronous or Asynchronous mode.

Note: PA = program address, PD = program data, D_{OUT} is the true data at the program address.

Figure 18.8 Program Operation Timings

Note: SA = sector address (for Sector Erase), VA = Valid Address for reading status data (see "Write Operation Status").

Figure 18.9 Chip/Sector Erase Operation Timings

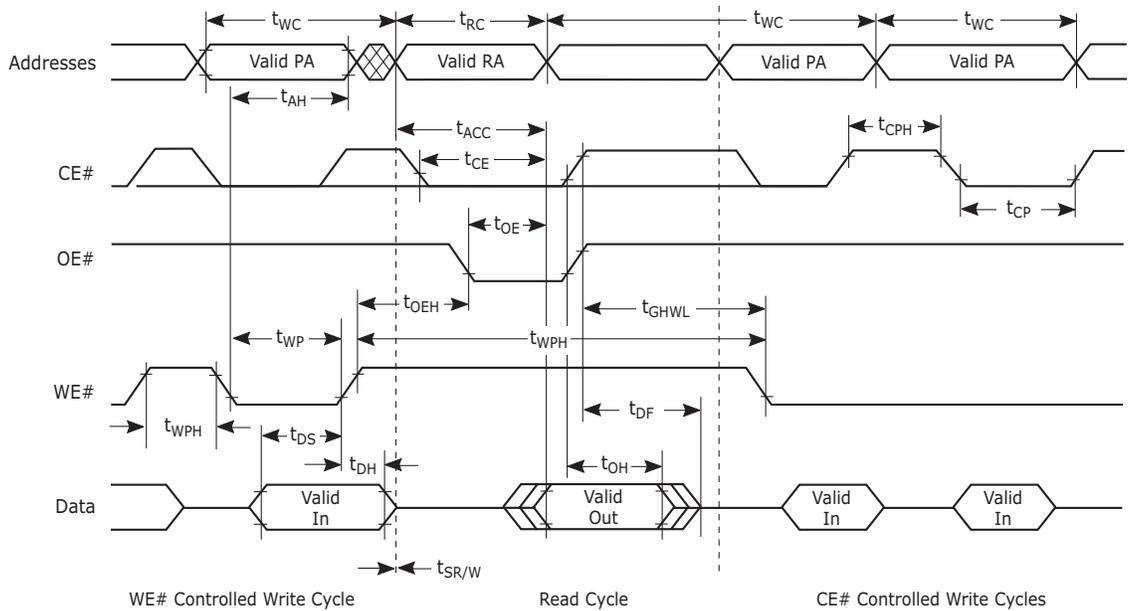

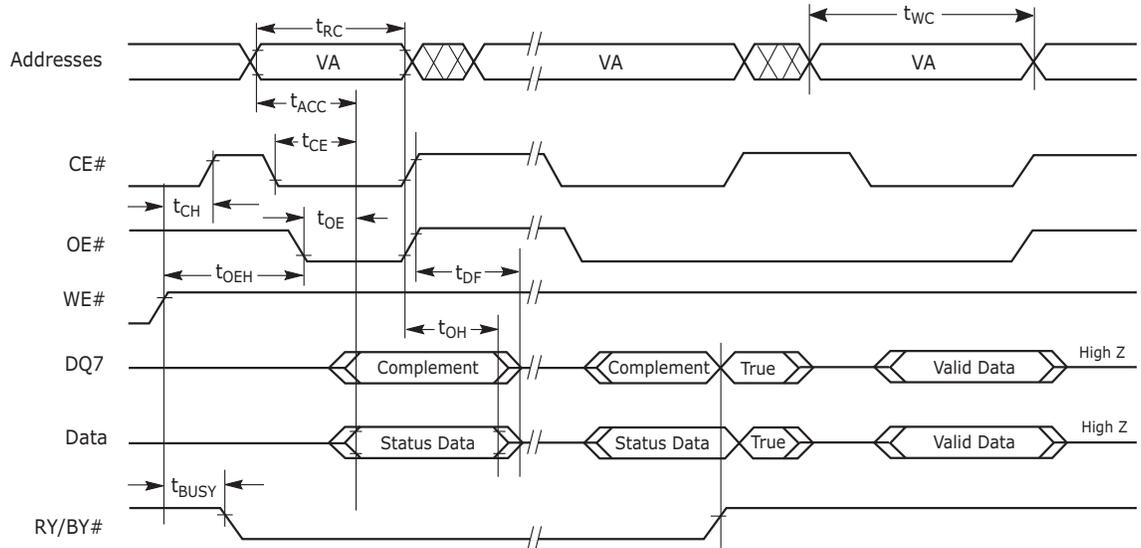

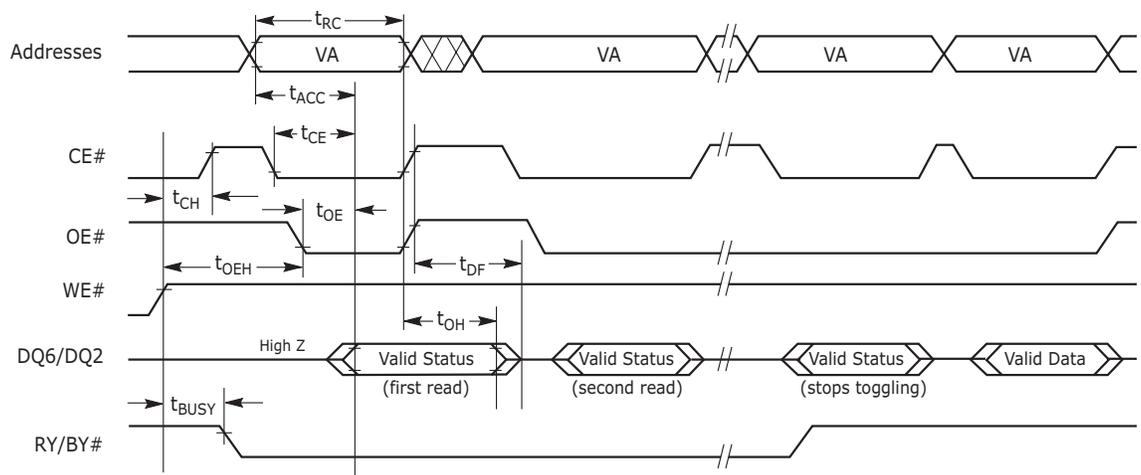

Figure 18.10 Back-to-back Cycle Timings

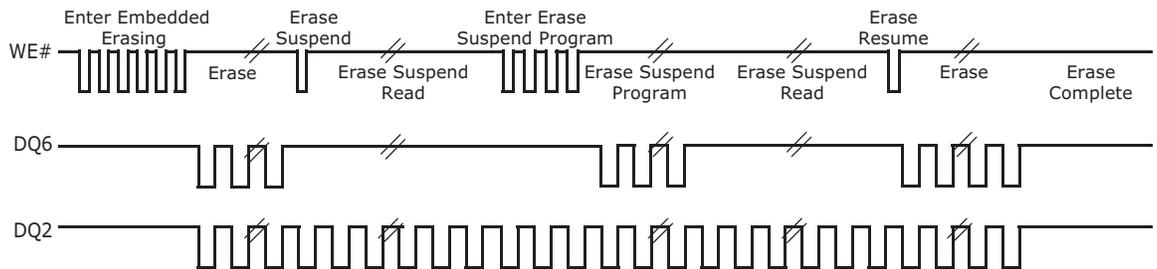

Note: VA = Valid address. Illustration shows first status cycle after command sequence, last status read cycle, and array data read cycle.

Figure I8.II Data# Polling Timings (During Embedded Algorithms)

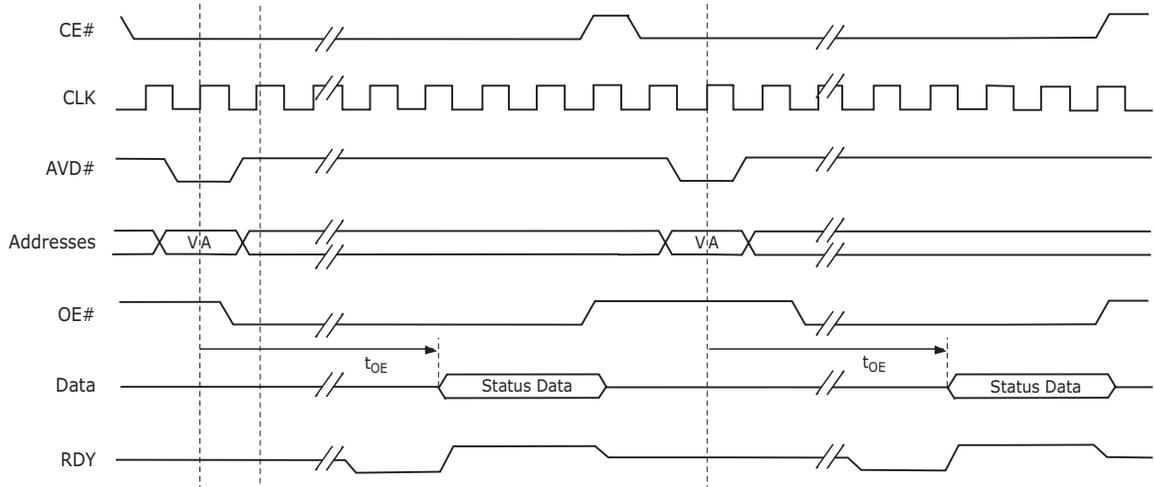

Note: VA = Valid address; not required for DQ6. Illustration shows first two status cycle after command sequence, last status read cycle, and array data read cycle.

Figure I8.I2 Toggle Bit Timings (During Embedded Algorithms)

Note: The system may use CE# or OE# to toggle DQ2 and DQ6. DQ2 toggles only when read at an address within an erase-suspended sector.

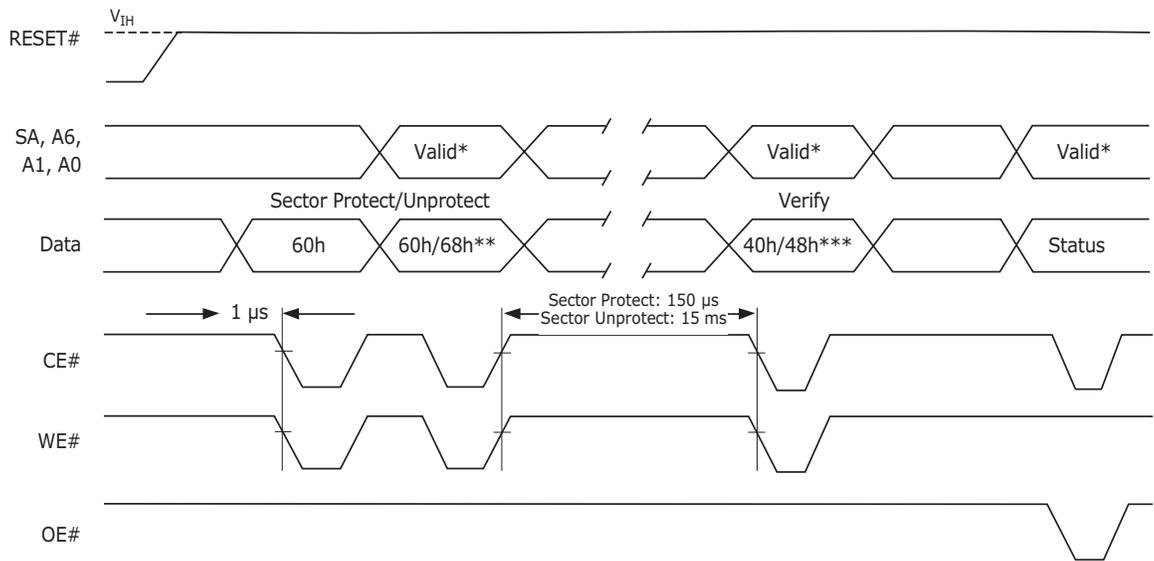

Figure I8.I3 DQ2 vs. DQ6 for Erase/Erase Suspend Operations

Notes:

1. The timings are similar to synchronous read timings and asynchronous data polling Timings/Toggle bit Timing.
2. VA = Valid Address. Two read cycles are required to determine status. When the Embedded Algorithm operation is complete, the toggle bits will stop toggling.
3. RDY is active with data (A18 = 0 in the Configuration Register). When A18 = 1 in the Configuration Register, RDY is active one clock cycle before data.
4. Data polling requires burst access time delay.

Figure 18.14 Synchronous Data Polling Timing/Toggle Bit Timings

- * Valid address for sector protect: A[7:0] = 3Ah. Valid address for sector unprotect: A[7:0] = 3Ah.
- ** Command for sector protect is 68h. Command for sector unprotect is 60h.
- *** Command for sector protect verify is 48h. Command for sector unprotect verify is 40h.

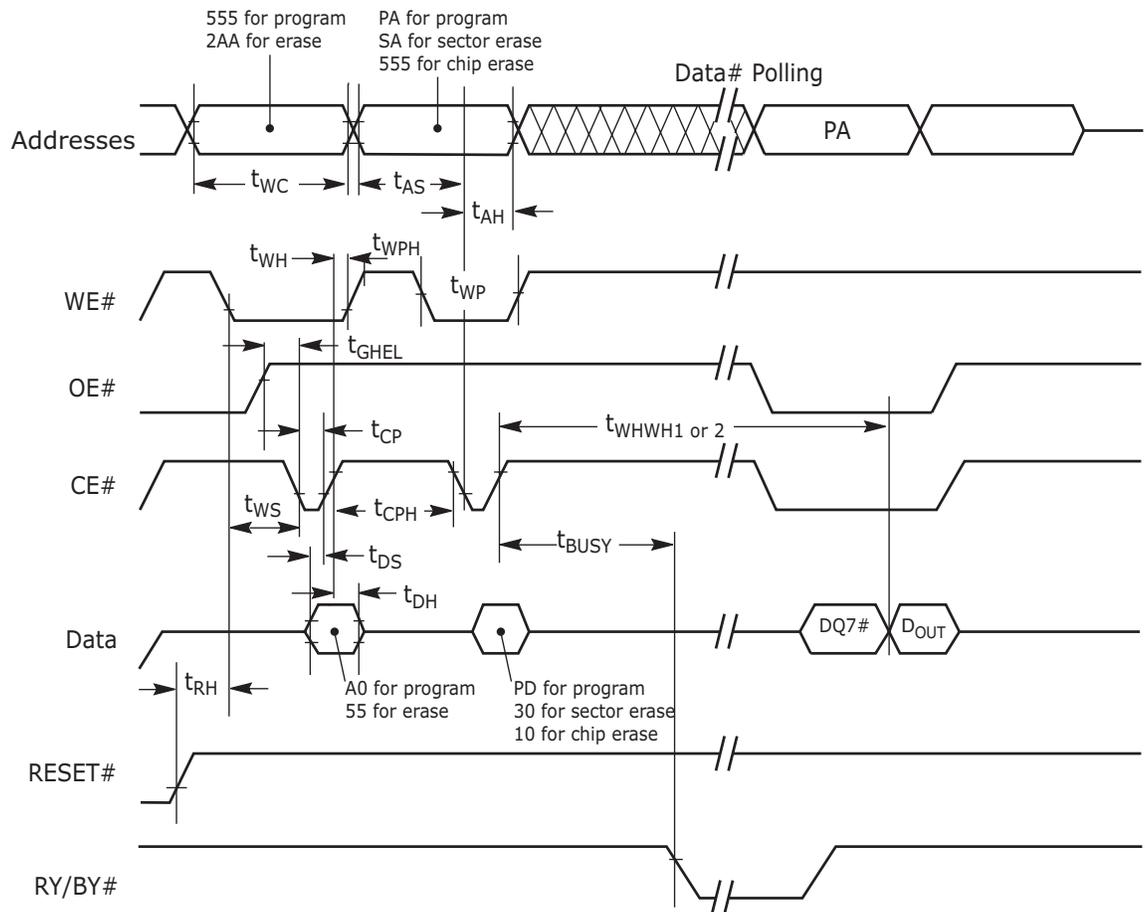

Figure 18.15 Sector Protect/Unprotect Timing Diagram

18.7 Alternate CE# Controlled Erase/Program Operations

| Parameter | | Description | | All Speed Options | Unit | |
|-------------|-------------|--|-------------|-------------------|------|---------|
| JEDEC | Std. | | | | | |
| t_{AVAV} | t_{WC} | Write Cycle Time (Note 1) | Min | 65 | ns | |
| t_{AVEL} | t_{AS} | Address Setup Time | Min | 0 | ns | |
| t_{ELAX} | t_{AH} | Address Hold Time | Min | 45 | ns | |
| t_{DVEH} | t_{DS} | Data Setup Time | Min | 35 | ns | |
| t_{EHDX} | t_{DH} | Data Hold Time | Min | 2 | ns | |
| t_{GHEL} | t_{GHEL} | Read Recovery Time Before Write(OE# High to WE# Low) | Min | 0 | ns | |
| t_{WLEL} | t_{WS} | WE# Setup Time | Min | 0 | ns | |
| t_{EHWH} | t_{WH} | WE# Hold Time | Min | 0 | ns | |
| | t_{WP} | WE# Width | Min | 25 | ns | |
| t_{ELEH} | t_{CP} | CE# Pulse Width | Min | 20 | ns | |
| t_{EHEL} | t_{CPH} | CE# Pulse Width High | Min | 30 | ns | |
| t_{WHWH1} | t_{WHWH1} | Programming Operation (Note 2) | Double-Word | Typ | 9 | μ s |
| t_{WHWH2} | t_{WHWH2} | Sector Erase Operation (Note 2) | | Typ | 0.5 | sec |
| | t_{WADVS} | WE# Rising Edge Setup to ADV# Falling Edge | Min | 11.75 | ns | |
| | t_{WCKS} | WE# Rising Edge Setup to CLK Rising Edge | Min | 5 | ns | |

Notes:

1. Not 100% tested.
2. See Command Definitions on page 71 for more information.

Notes:

1. PA = program address, PD = program data, $DQ7\#$ = complement of the data written to the device, D_{OUT} = data written to the device.
2. Figure indicates the last two bus cycles of the command sequence.

Figure 18.16 Alternate CE# Controlled Write Operation Timings

18.8 Erase and Programming Performance

Table 18.6 Erase and Programming Performance

| Parameter | Typ (Note 1) | Max (Note 2) | Unit | Comments |
|--------------------------------------|---------------------------------|----------------------------|------|---|
| Sector Erase Time | 0.5 | 5 | s | Excludes 00h programming prior to erasure (Note 4) |
| Chip Erase Time | 16 Mb = 46 32 Mb = 78 | 16 Mb = 230 32 Mb = 460 | s | |
| Double Word Program Time | 8 | 130 | μs | Excludes system level overhead (Note 5) |
| Accelerated Double Word Program Time | 8 | 130 | μs | |
| Accelerated Chip Program Time | 16 Mb = 5 32 Mb = 10 | 16 Mb = 50 32 Mb = 100 | s | |
| Chip Program Time (Note 3) | x32 16 Mb = 12 32 Mb = 24 | 16 Mb = 120 32 Mb = 240 | s | |

Notes:

1. Typical program and erase times assume the following conditions: 25°C, 2.5 V V_{CC} , 100K cycles. Additionally, programming typicals assume checkerboard pattern.
2. Under worst case conditions of 145°C, $V_{CC} = 2.5$ V, 1M cycles.
3. The typical chip programming time is considerably less than the maximum chip programming time listed.
4. In the pre-programming step of the Embedded Erase algorithm, all bytes are programmed to 00h before erasure.
5. System-level overhead is the time required to execute the two- or four-bus-cycle sequence for the program command. See Table 20.1 and Table 20.2 for further information on command definitions.
6. PPBs have a program/erase cycle endurance of 100 cycles.
7. Guaranteed cycles per sector is 100K minimum.

18.9 Latchup Characteristics

Table 18.7 Latchup Characteristics

| Description | Min | Max |
|---|---------|------------------|
| Input voltage with respect to V_{SS} on all pins except I/O pins (including A9, ACC, and WP#) | -1.0 V | 12.5 V |
| Input voltage with respect to V_{SS} on all I/O pins | -1.0 V | $V_{CC} + 1.0$ V |
| V_{CC} Current | -100 mA | +100 mA |

Note: Includes all pins except V_{CC} . Test conditions: $V_{CC} = 3.0$ V, one pin at a time.

18.10 PQFP and Fortified BGA Pin Capacitance

Table 18.8 PQFP and Fortified BGA Pin Capacitance

| Parameter Symbol | Parameter Description | Test Setup | Typ | Max | Unit |
|------------------|-------------------------|---------------|-----|-----|------|
| C_{IN} | Input Capacitance | $V_{IN} = 0$ | 6 | 7.5 | pF |
| C_{OUT} | Output Capacitance | $V_{OUT} = 0$ | 8.5 | 12 | pF |
| C_{IN2} | Control Pin Capacitance | $V_{IN} = 0$ | 7.5 | 9 | pF |

Notes:

1. Sampled, not 100% tested.
2. Test conditions $T_A = 25^\circ\text{C}$, $f = 1.0$ MHz.

19 Appendix I

19.1 Common Flash Memory Interface (CFI)

The Common Flash Interface (CFI) specification outlines device and host system software interrogation handshake, which allows specific vendor-specified software algorithms to be used for entire families of devices. Software support can then be device-independent, JEDEC ID-independent, and forward- and backward-compatible for the specified flash device families. Flash vendors can standardize existing interfaces for long-term compatibility.

This device enters the CFI Query mode when the system writes the CFI Query command, 98h, to address 55h in word mode (or address AAh in byte mode), any time the device is ready to read array data. The system can read CFI information at the addresses given in [Table 19.1-Table 19.3](#). In order to terminate reading CFI data, the system must write the reset command.

The system can also write the CFI query command when the device is in the autoselect mode. The device enters the CFI query mode, and the system can read CFI data at the addresses given in [Table 19.1-Table 19.3](#). The system must write the reset command to return the device to the autoselect mode.

For further information, please refer to the CFI Specification and CFI Publication 100, available via the World Wide Web at <http://www.amd.com/products/nvd/overview/cfi.html> or contact a Spansion representative for copies of these documents.

Table 19.1 CFI Query Identification String

| Addresses | Data | Description |
|-------------------|-------------------------|--|
| 10h 11h 12h | 0051h 0052h 0059h | Query Unique ASCII string <i>QRY</i> |
| 13h 14h | 0002h 0000h | Primary OEM Command Set |
| 15h 16h | 0040h 0000h | Address for Primary Extended Table |
| 17h 18h | 0000h 0000h | Alternate OEM Command Set (00h = none exists) |
| 19h 1Ah | 0000h 0000h | Address for Alternate OEM Extended Table (00h = none exists) |

Table 19.2 CFI System Interface String

| Addresses | Data | Description |
|-----------|-------------------|--|
| 1Bh | (see description) | V _{CC} Min. (write/erase) DQ7–DQ4: volts, DQ3–DQ0: 100 millivolt 0023h = S29CD-J devices 0030h = S29CL-J devices |
| 1Ch | (see description) | V _{CC} Max. (write/erase) DQ7–DQ4: volts, DQ3–DQ0: 100 millivolt 0027h = S29CD-J devices 0036h = S29CL-J devices |
| 1Dh | 0000h | V _{PP} Min. voltage (00h = no V _{PP} pin present) |
| 1Eh | 0000h | V _{PP} Max. voltage (00h = no V _{PP} pin present) |
| 1Fh | 0004h | Typical timeout per single word/doubleword program 2 ⁿ μs |
| 20h | 0000h | Typical timeout for Min. size buffer program 2 ⁿ μs (00h = not supported) |
| 21h | 0009h | Typical timeout per individual block erase 2 ⁿ ms |
| 22h | 0000h | Typical timeout for full chip erase 2 ⁿ ms (00h = not supported) |
| 23h | 0005h | Max. timeout for word/doubleword program 2 ⁿ times typical |
| 24h | 0000h | Max. timeout for buffer write 2 ⁿ times typical |
| 25h | 0007h | Max. timeout per individual block erase 2 ⁿ times typical |
| 26h | 0000h | Max. timeout for full chip erase 2 ⁿ times typical (00h = not supported) |

Table 19.3 Device Geometry Definition

| Addresses | Data | Description |
|--------------------------|--|---|
| 27h | (see description) | Device Size = 2 ⁿ byte 0015h = 16 Mb device 0016h = 32 Mb device |
| 28h 29h | 0003h 0000h | Flash Device Interface description (for complete description, please refer to CFI publication 100) 0000 = x8-only asynchronous interface 0001 = x16-only asynchronous interface 0002 = supports x8 and x16 via BYTE# with asynchronous interface 0003 = x 32-only asynchronous interface 0005 = supports x16 and x32 via WORD# with asynchronous interface |
| 2Ah 2Bh | 0000h 0000h | Max. number of byte in multi-byte program = 2 ⁿ (00h = not supported) |
| 2Ch | 0003h | Number of Erase Block Regions within device |
| 2Dh 2Eh 2Fh 30h | 0007h 0000h 0020h 0000h | Erase Block Region 1 Information (refer to the CFI specification or CFI publication 100) |
| 31h 32h 33h 34h | (See description) 0000h 0000h 0001h | Erase Block Region 2 Information (refer to the CFI specification or CFI publication 100) Address 31h data: 001Dh = 16 Mb device 003Dh = 32 Mb device |
| 35h 36h 37h 38h | 0007h 0000h 0020h 0000h | Erase Block Region 3 Information (refer to the CFI specification or CFI publication 100) |
| 39h 3Ah 3Bh 3Ch | 0000h 0000h 0000h 0000h | Erase Block Region 4 Information (refer to the CFI specification or CFI publication 100) |

Table 19.4 CFI Primary Vendor-Specific Extended Query

| Addresses | Data | Description |
|-------------------|-------------------------|--|
| 40h 41h 42h | 0050h 0052h 0049h | Query-unique ASCII string <i>PRI</i> |
| 43h | 0031h | Major version number, ASCII (reflects modifications to the silicon) |
| 44h | 0033h | Minor version number, ASCII (reflects modifications to the CFI table) |
| 45h | 0004h | Address Sensitive Unlock (DQ1, DQ0) 00 = Required, 01 = Not Required Silicon Revision Number (DQ5–DQ2) 0000 = CS49 0001 = CS59 0010 = CS99 0011 = CS69 0100 = CS119 |
| 46h | 0002h | Erase Suspend (1 byte) 00 = Not Supported 01 = To Read Only 02 = To Read and Write |
| 47h | 0001h | Sector Protect (1 byte) 00 = Not Supported, X = Number of sectors in per group |
| 48h | 0000h | Temporary Sector Unprotect 00h = Not Supported, 01h = Supported |
| 49h | 0006h | Sector Protect/Unprotect scheme (1 byte) 01 = 29F040 mode, 02 = 29F016 mode 03 = 29F400 mode, 04 = 29LV800 mode 05 = 29BDS640 mode (Software Command Locking) 06 = BDD160 mode (New Sector Protect) 07 = 29LV800 + PDL128 (New Sector Protect) mode |
| 4Ah | 0037h | Simultaneous Read/Write (1 byte) 00h = Not Supported, X = Number of sectors in all banks except Bank 1 |
| 4Bh | 0001h | Burst Mode Type 00h = Not Supported, 01h = Supported |
| 4Ch | 0000h | Page Mode Type 00h = Not Supported, 01h = 4 Word Page, 02h = 8 Word Page |
| 4Dh | 00B5h | ACC (Acceleration) Supply Minimum 00h = Not Supported (DQ7–DQ4: volt in hex, DQ3–DQ0: 100 mV in BCD) |
| 4Eh | 00C5h | ACC (Acceleration) Supply Maximum 00h = Not Supported, (DQ7–DQ4: volt in hex, DQ3–DQ0: 100 mV in BCD) |
| 4Fh | 0001h | Top/Bottom Boot Sector Flag (1 byte) 00h = Uniform device, no WP# control, 01h = 8 x 8 Kb sectors at top and bottom with WP# control 02h = Bottom boot device 03h = Top boot device 04h = Uniform, Bottom WP# Protect 05h = Uniform, Top WP# Protect If the number of erase block regions = 1, then ignore this field |
| 50h | 0001h | Program Suspend 00 = Not Supported 01 = Supported |
| 51h | 0000h | Write Buffer Size 2 ^(N+1) word(s) |
| 57h | 0002h | Bank Organization (1 byte) 00 = If data at 4Ah is zero XX = Number of banks |
| 58h | 0017h | Bank 1 Region Information (1 byte) XX = Number of Sectors in Bank 1 |
| 59h | 0037h | Bank 2 Region Information (1 byte) XX = Number of Sectors in Bank 2 |
| 5Ah | 0000h | Bank 3 Region Information (1 byte) XX = Number of Sectors in Bank 3 |
| 5Bh | 0000h | Bank 4 Region Information (1 byte) XX = Number of Sectors in Bank 4 |

20 Appendix 2

20.1 Command Definitions

Table 20.1 Memory Array Command Definitions (x32 Mode)

| Command (Notes) | | Cycles | Bus Cycles (Notes 1–4) | | | | | | | | | | | |
|------------------------------------|-----------------|--------|------------------------|------|--------|------|--------|------|--------|------|--------|------|--------|-------|
| | | | First | | Second | | Third | | Fourth | | Fifth | | Sixth | |
| | | | Addr | Data | Addr | Data | Addr | Data | Addr | Data | Addr | Data | Addr | Data |
| Read (5) | | 1 | RA | RD | | | | | | | | | | |
| Reset (6) | | 1 | XXX | FO | | | | | | | | | | |
| Autoselect (7) | Manufacturer ID | 4 | 555 | AA | 2AA | 55 | 555 | 90 | BA+X00 | 01 | | | | |
| | Device ID (11) | 6 | 555 | AA | 2AA | 55 | 555 | 90 | BA+X01 | 7E | BA+X0E | 09 | BA+X0F | 00/01 |
| Program | | 4 | 555 | AA | 2AA | 55 | 555 | A0 | PA | PD | | | | |
| Chip Erase | | 6 | 555 | AA | 2AA | 55 | 555 | 80 | 555 | AA | 2AA | 55 | 555 | 10 |
| Sector Erase | | 6 | 555 | AA | 2AA | 55 | 555 | 80 | 555 | AA | 2AA | 55 | SA | 30 |
| Program/Erase Suspend (12) | | 1 | BA | B0 | | | | | | | | | | |
| Program/Erase Resume (13) | | 1 | BA | 30 | | | | | | | | | | |
| CFI Query (14, 15) | | 1 | 55 | 98 | | | | | | | | | | |
| Accelerated Program (16) | | 2 | XX | A0 | PA | PD | | | | | | | | |
| Configuration Register Verify (15) | | 3 | 555 | AA | 2AA | 55 | BA+555 | C6 | BA+XX | RD | | | | |
| Configuration Register Write (17) | | 4 | 555 | AA | 2AA | 55 | 555 | D0 | XX | WD | | | | |
| Unlock Bypass Entry (18) | | 3 | 555 | AA | 2AA | 55 | 555 | 20 | | | | | | |
| Unlock Bypass Program (18) | | 2 | XX | A0 | PA | PD | | | | | | | | |
| Unlock Bypass Erase (18) | | 2 | XX | 80 | XX | 10 | | | | | | | | |
| Unlock Bypass CFI (14, 18) | | 1 | XX | 98 | | | | | | | | | | |
| Unlock Bypass Reset (18) | | 2 | XX | 90 | XX | 00 | | | | | | | | |

Legend:

BA = Bank Address. The set of addresses that comprise a bank. The system may write any address within a bank to identify that bank for a command.

PA = Program Address (Amax–A0). Addresses latch on the falling edge of the WE# or CE# pulse, whichever happens later.

PD = Program Data (DQmax–DQ0) written to location PA. Data latches on the rising edge of WE# or CE# pulse, whichever happens first.

Notes:

- See Table 8.1 for description of bus operations.
- All values are in hexadecimal.
- Shaded cells in table denote read cycles. All other cycles are write operations.
- During unlock cycles, (lower address bits are 555 or 2AAh as shown in table) address bits higher than A11 (except where BA is required) and data bits higher than DQ7 are don't cares.
- No unlock or command cycles required when bank is reading array data.
- The Reset command is required to return to the read mode (or to the erase-suspend-read mode if previously in Erase Suspend) when a bank is in the autoselect mode, or if DQ5 goes high (while the bank is providing status information).
- The fourth cycle of the autoselect command sequence is a read cycle. The system must provide the bank address to obtain the manufacturer ID or device ID information. See "Autoselect" for more information.
- This command cannot be executed until The Unlock Bypass command must be executed before writing this command sequence. The Unlock Bypass Reset command must be executed to return to normal operation.
- This command is ignored during any embedded program, erase or suspended operation.
- Valid read operations include asynchronous and burst read mode operations.
- The device ID must be read across the fourth, fifth, and sixth cycles. 00h in the sixth cycle indicates ordering option 00, 01h indicates ordering option 01.
- The system may read and program in non-erasing sectors when in the Program/Erase Suspend mode. The Program/Erase Suspend command is valid only during a sector erase operation, and requires the bank address.
- The Program/Erase Resume command is valid only during the Erase Suspend mode, and requires the bank address.
- Command is valid when device is ready to read array data.
- Asynchronous read operations.
- ACC must be at V_{LD} during the entire operation of this command.
- Command is ignored during any Embedded Program, Embedded Erase, or Suspend operation.
- The Unlock Bypass Entry command is required prior to any Unlock Bypass operation. The Unlock Bypass Reset command is required to return to the read mode.

RA = Read Address (Amax–A0).

RD = Read Data. Data DQmax–DQ0 at address location RA.

SA = Sector Address. The set of addresses that comprise a sector. The system may write any address within a sector to identify that sector for a command.

WD = Write Data. See "Configuration Register" definition for specific write data. Data latched on rising edge of WE#.

X = Don't care

Table 20.2 Sector Protection Command Definitions (x32 Mode)

| Command (Notes) | Cycles | Bus Cycles (Notes 1 – 4) | | | | | | | | | | | |
|---|--------|--------------------------|------|--------|------|--------|------|----------|----------|-------|------|-------|-------|
| | | First | | Second | | Third | | Fourth | | Fifth | | Sixth | |
| | | Addr | Data | Addr | Data | Addr | Data | Addr | Data | Addr | Data | Addr | Data |
| Reset | 1 | XXX | F0 | | | | | | | | | | |
| Secured Silicon Sector Entry | 3 | 555 | AA | 2AA | 55 | 555 | 88 | | | | | | |
| Secured Silicon Sector Exit | 4 | 555 | AA | 2AA | 55 | 555 | 90 | XX | 00 | | | | |
| Secured Silicon Protection Bit Program (5, 6) | 6 | 555 | AA | 2AA | 55 | 555 | 60 | OW | 68 | OW | 48 | OW | RD(0) |
| Secured Silicon Protection Bit Status | 6 | 555 | AA | 2AA | 55 | 555 | 60 | OW | RD(0) | | | | |
| Password Program (5, 7, 8) | 4 | 555 | AA | 2AA | 55 | 555 | 38 | PWA[0-1] | PWD[0-1] | | | | |
| Password Verify | 4 | 555 | AA | 2AA | 55 | 555 | C8 | PWA[0-1] | PWD[0-1] | | | | |
| Password Unlock (7, 8) | 5 | 555 | AA | 2AA | 55 | 555 | 28 | PWA[0-1] | PWD[0-1] | | | | |
| PPB Program (5, 6) | 6 | 555 | AA | 2AA | 55 | 555 | 60 | SG+WP | 68 | SG+WP | 48 | SG+WP | RD(0) |
| All PPB Erase (5, 9, 10) | 6 | 555 | AA | 2AA | 55 | 555 | 60 | WP | 60 | WP | 40 | WP | RD(0) |
| PPB Status (11, 12) | 4 | 555 | AA | 2AA | 55 | BA+555 | 90 | SA+X02 | 00/01 | | | | |
| PPB Lock Bit Set | 3 | 555 | AA | 2AA | 55 | 555 | 78 | | | | | | |
| PPB Lock Bit Status | 4 | 555 | AA | 2AA | 55 | BA+555 | 58 | SA | RD(1) | | | | |
| DYB Write (7) | 4 | 555 | AA | 2AA | 55 | 555 | 48 | SA | X1 | | | | |
| DYB Erase (7) | 4 | 555 | AA | 2AA | 55 | 555 | 48 | SA | X0 | | | | |
| DYB Status (12) | 4 | 555 | AA | 2AA | 55 | BA+555 | 58 | SA | RD(0) | | | | |
| PPMLB Program (5, 6) | 6 | 555 | AA | 2AA | 55 | 555 | 60 | PL | 68 | PL | 48 | PL | RD(0) |
| PPMLB Status (5) | 6 | 555 | AA | 2AA | 55 | 555 | 60 | PL | RD(0) | | | | |
| SPMLB Program (5, 6) | 6 | 555 | AA | 2AA | 55 | 555 | 60 | SL | 68 | SL | 48 | SL | RD(0) |
| SPMLB Status (5) | 6 | 555 | AA | 2AA | 55 | 555 | 60 | SL | RD(0) | | | | |

Legend:

DYB = Dynamic Protection Bit
 OW = Address (A5–A0) is (011X10).
 PPB = Persistent Protection Bit
 PWA = Password Address. A0 selects between the low and high 32-bit portions of the 64-bit Password
 PWD = Password Data. Must be written over two cycles.
 PL = Password Protection Mode Lock Address (A5–A0) is (001X10)
 RD(0) = Read Data DQ0 protection indicator bit. If protected, DQ0 = 1, if unprotected, DQ0 = 0.
 RD(1) = Read Data DQ1 protection indicator bit. If protected, DQ1 = 1, if unprotected, DQ1 = 0.

SA = Sector Address. The set of addresses that comprise a sector. The system may write any address within a sector to identify that sector for a command.
 SG = Sector Group Address
 BA = Bank Address. The set of addresses that comprise a bank. The system may write any address within a bank to identify that bank for a command.
 SL = Persistent Protection Mode Lock Address (A5–A0) is (010X10)
 WP = PPB Address (A5–A0) is (111010)
 X = Don't care
 PPMLB = Password Protection Mode Locking Bit
 SPMLB = Persistent Protection Mode Locking Bit

Notes:

- See Table 8.1 for description of bus operations.
- All values are in hexadecimal.
- Shaded cells in table denote read cycles. All other cycles are write operations.
- During unlock cycles, (lower address bits are 555 or 2AAh as shown in table) address bits higher than A11 (except where BA is required) and data bits higher than DQ7 are don't cares.
- The reset command returns the device to reading the array.
- The fourth cycle programs the addressed locking bit. The fifth and sixth cycles are used to validate whether the bit has been fully programmed. If DQ0 (in the sixth cycle) reads 0, the program command must be issued and verified again.
- Data is latched on the rising edge of WE#.
- The entire four bus-cycle sequence must be entered for each portion of the password.
- The fourth cycle erases all PPBs. The fifth and sixth cycles are used to validate whether the bits have been fully erased. If DQ0 (in the sixth cycle) reads 1, the erase command must be issued and verified again.
- Before issuing the erase command, all PPBs should be programmed in order to prevent over-erasure of PPBs.
- In the fourth cycle, 00h indicates PPB set; 01h indicates PPB not set.
- The status of additional PPBs and DYBs may be read (following the fourth cycle) without reissuing the entire command sequence.

2I Revision Summary

Revision A (March 1, 2005)

Initial release.

Revision AI (April 15, 2005)

Ordering Information and Valid Combinations tables

Updated to include lead (Pb)-free options

Rev A2 (January 20, 2006)

Ordering Information

Added "Contact factory" for 75 MHz

Modified Ordering Options for Characters 15 & 16 to reflect autoselect ID & top/bottom boot.

Changed "N" for Extended Temperature Range to "M".

Input/Output Descriptions

Removed Logic Symbol Diagrams

Additional Resources

Added Additional Resources section

Memory Address Map

Changed "Bank 2" to "Bank 1"

Simultaneous Read/Write Operation

Removed Ordering Options Table (Tables 3 & 4)

Advanced Sector Protection/Unprotection

Added Figure: Advanced Sector Protection/Unprotection

Added Figures for PPB Erase & Program Algorithm

Electronic Marking

Added in Electronic Marking section

Absolute Maximum Ratings

Modified V_{CC} Ratings to reflect 2.6 V and 3.6 V devices

Modified V_{CC} Ratings to reflect 16 Mb & 32 Mb devices

AC Characteristics

Added Note " t_{OE} during Read Array"

Table: Asynchronous Read Operation

Changed values of t_{AVAV} , t_{AVQV} , t_{ELQV} , t_{GLQV}

Figure: Conventional Read Operation Timings

Moved t_{DF} line to 90% on the high-Z output

Table: Burst Mode Read for 32 Mb & 16 Mb

Added t_{AAVS} and t_{AAVH} timing parameters.

Changed t_{CH} to t_{CLKH}

Changed t_{CL} to t_{CLKL}

Removed the following timing parameters

- t_{DS} (Data Setup to WE# Rising Edge)

- t_{DH} (Data Hold from WE# Rising Edge)
- t_{AS} (Address Setup to Falling Edge of WE#)
- t_{AH} (Address Hold from Falling Edge of WE#)
- t_{CS} (CE# Setup Time)
- t_{CH} (CE# Hold Time)
- t_{ACS} (Address Setup Time to CLK)
- t_{ACH} (Address Hold Time from ADV# Rising Edge of CLK while ADV# is Low)

Figure: Burst Mode Read (x32 Mode)

Added the following timing parameters

- t_{AAVS}
- t_{DVCH}
- t_{INDS}
- t_{INDH}

Figure: Asynchronous Command Write Timing

Changed t_{OEH} to t_{WEH}

Change t_{WPH} to t_{OEP}

Figure: Synchronous Command Write/Read Timing

Removed t_{WADVH} and t_{WCKS}

Figure: WP# Timing

Changed t_{CH} to t_{BUSY}

Table: Erase/Program Operations

Added Note 3: Program/Erase parameters are the same regardless of synchronous or asynchronous mode.

Add t_{OEP} (OE High Pulse)

Alternative CE# Controlled Erase/Program Operations

Removed t_{OES}

Added t_{WADVS} and t_{WCKS}

Appendix 2: Command Definitions

Removed "or when device is in autoselect mode" from Note 14

Rev B0 (June 12, 2006)

Global

Changed document status to Preliminary.

Distinctive Characteristics

Changed cycling endurance from typical to guaranteed.

Performance Characteristics

Updated Max Asynch. Access Time, Max CE# Access Time, and Max OE# Access time in table.

Ordering Information

Updated additional ordering options in designator breakout table. Updated valid combination tables.

Input/Output Descriptions and Logic Symbols

Changed RY/BY# description.

Physical Dimensions/Connection Diagrams

Changed note on connection diagrams.

Additional Resources

Updated contact information.

Hardware Reset (RESET#)

Added section.

Autoselect

Updated third and fourth paragraphs in section. Updated Autoselect Codes table.

Erase Suspend / Erase Resume Commands

Modified second paragraph. Replaced allowable operations table with bulleted list.

Program Suspend / Program Resume Commands

Replaced allowable operations table with bulleted list.

Reset Command

Added section.

Secured Silicon Sector Flash Memory Region

Modified Secured Silicon Sector Addresses table.

Absolute Maximum Ratings

Modified V_{CC} and V_{IO} ratings. Modified Note 1.

Operating Ranges

Modified specification titles and descriptions (no specification value changes).

DC Characteristics, CMOS Compatible table

Modified I_{CCB} specification. Deleted Note 5. Added Note 3 references to table.

Burst Mode Read for 32 Mb and 16 Mb table

Modified t_{ADVCS} , t_{CLKH} , t_{CLKL} , t_{AAVS} specifications. Added t_{RSTZ} , t_{WAVDH1} , and t_{WAVDH2} specifications. Added Notes 2 and 3, and note references to table.

Burst Mode Read (x32 Mode) figure

Added t_{AAVH} , deleted t_{DVCH} .

Synchronous Command Write/Read Timing figure

Added t_{WAVDH1} and t_{WAVDH2} to figure. Deleted t_{ACS} and t_{ACH} from figure.

Hardware Reset (RESET#)

Added table to section.

Erase/Program Operations table

Added note references. Deleted t_{OEP} specification.

Erase and Programming Performance

Changed Double Word Program Time specification.

Common Flash Memory Interface (CFI)

CFI System Interface String table: Changed description and data for addresses 1Bh and 1Ch.

Device Geometry Definition table: Changed description and data for address 27h.

Rev BI (September 27, 2006)**Distinctive Characteristics**

Changed cycling endurance specification to typical.

Performance Characteristics

Changed t_{BACC} specifications for 66 MHz, 56 MHz, 40 MHz speed options.

Ordering Information

Added quantities to packing type descriptions, restructured table for easier reference.

Table 8.7, S29CD-J & S29CL-J Flash Family Autoselect Codes (High Voltage Method)

Modified description of read cycle 3 DQ7–DQ0.

Table 8.8, DQ6 and DQ2 Indications

Corrected third column heading

Section 8.9, Reset Command

Added table.

Section 13.1, Absolute Maximum Ratings

Deleted OE# from section.

Table 18.3, Burst Mode Read for 32 Mb and 16 Mb

Changed t_{ADVCS} , t_{BDH} specifications. Modified description for t_{IACC} . Deleted minimum specifications for t_{AAVH} .

Figure 18.4, Burst Mode Read (x32 Mode)

Modified period for t_{IACC} in drawing.

Colophon

The products described in this document are designed, developed and manufactured as contemplated for general use, including without limitation, ordinary industrial use, general office use, personal use, and household use, but are not designed, developed and manufactured as contemplated (1) for any use that includes fatal risks or dangers that, unless extremely high safety is secured, could have a serious effect to the public, and could lead directly to death, personal injury, severe physical damage or other loss (i.e., nuclear reaction control in nuclear facility, aircraft flight control, air traffic control, mass transport control, medical life support system, missile launch control in weapon system), or (2) for any use where chance of failure is intolerable (i.e., submersible repeater and artificial satellite). Please note that Spansion will not be liable to you and/or any third party for any claims or damages arising in connection with above-mentioned uses of the products. Any semiconductor device has an inherent chance of failure. You must protect against injury, damage or loss from such failures by incorporating safety design measures into your facility and equipment such as redundancy, fire protection, and prevention of over-current levels and other abnormal operating conditions. If any products described in this document represent goods or technologies subject to certain restrictions on export under the Foreign Exchange and Foreign Trade Law of Japan, the US Export Administration Regulations or the applicable laws of any other country, the prior authorization by the respective government entity will be required for export of those products.
