

# 2.5V or 3.3V, 200-MHz, 12-Output Zero Delay Buffer

## Features

- Output frequency range: 8.33 MHz to 200 MHz
- Input frequency range: 6.25 MHz to 125 MHz
- 2.5V or 3.3V operation
- Split 2.5V/3.3V outputs
- ±2% max. Output duty cycle variation
- 7 ps RMS typical Cycle-to-cycle jitter
- 6 ps RMS typical Period jitter
- 12 clock outputs: drive up to 24 clock lines
- One feedback output
- Three reference clock inputs: crystal or LVCMOS
- 300 ps max. output-output skew
- Phase-locked loop (PLL) bypass mode
- Spread Aware™
- Output enable/disable
- Pin-compatible with MPC9772 and MPC972
- Industrial temperature range: -40°C to +85°C
- 52-pin 1.0-mm TQFP package

## Description

The CY29772 is a low-voltage high-performance 200-MHz PLL-based zero delay buffer designed for high-speed clock-distribution applications.

The CY29772 features one on-chip crystal oscillator and two LVCMOS reference clock inputs and provides 12 outputs partitioned in three banks of four outputs each. Each bank divides the VCO output per SEL(A:C) settings, see *Functional Table*. These dividers allow output to input ratios of 8:1, 6:1, 5:1, 4:1, 3:1, 8:3, 5:2, 2:1, 5:3, 3:2, 4:3, 5:4, 1:1, and 5:6. Each LVCMOS-compatible output can drive 50Ω series- or parallel-terminated transmission lines. For series-terminated transmission lines, each output can drive one or two traces, giving the device an effective fanout of 1:24.

The PLL is ensured stable given that the VCO is configured to run between 200 MHz to 500 MHz. This allows a wide range of output frequencies from 8 MHz to 200 MHz. For normal operation, the external feedback input, FB\_IN, is connected to the feedback output, FB\_OUT. The internal VCO is running at multiples of the input reference clock set by the feedback divider, see *Frequency Table*.

When PLL\_EN is LOW, PLL is bypassed and the reference clock directly feeds the output dividers. This mode is fully static and the minimum input clock frequency specification does not apply.

**Notes:**

1. PU = Internal pull-up, PD = Internal pull-down.
2. A 0.1- $\mu$ F bypass capacitor should be placed as close as possible to each positive power pin (<0.2"). If these bypass capacitors are not close to the pins their high-frequency filtering characteristics will be cancelled by the lead inductance of the traces.
3. AVDD and VDD pins must be connected to a power supply level that is at least equal or higher than that of VDDQA, VDDQB, and VDDQC power supply pins.

**SYNC Output**

In situations where output frequency relationships are not integer multiples of each other the SYNC output provides a signal for system synchronization. The CY29772 monitors the relationship between the QA and the QC output clocks. It provides a low going pulse, one period in duration, one period prior to the coincident rising edges of the QA and QC outputs.

The duration and the placement of the pulse depend on the higher of the QA and QC output frequencies. *Figure 1* illustrates various waveforms for the SYNC output. Note that the SYNC output is defined for all possible combinations of the QA and QC outputs even though under some relationships the lower frequency clock could be used as a synchronizing signal.

**Figure 1.**

## Power Management

The individual output enable/freeze control of the CY29772 allows the user to implement unique power management schemes into the design. The outputs are stopped in the logic '0' state when the freeze control bits are activated. The serial input register contains one programmable freeze enable bit for 12 of the 14 output clocks. The QC0 and FB\_OUT outputs can not be frozen with the serial port, this avoids any potential lock up situation should an error occur in the loading of the serial

data. An output is frozen when a logic '0' is programmed and enabled when a logic '1' is written. The enabling and freezing of individual outputs is done in such a manner as to eliminate the possibility of partial "runt" clocks.

The serial input register is programmed through the SDATA input by writing a logic '0' start bit followed by 12 NRZ freeze enable bits. The period of each SDATA bit equals the period of the free running SCLK signal. The SDATA is sampled on the rising edge of SCLK.

Start Bit	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	D10	D11
-----------	----	----	----	----	----	----	----	----	----	----	-----	-----

D0-D3 are the control bits for QA0-QA3, respectively  
D4-D7 are the control bits for QB0-QB3, respectively  
D8-D10 are the control bits for QC1-QC3, respectively  
D11 is the control bit for SYNC
