The S-29430A is high speed, low power 8K-bit serial E²PROM with a wide operating voltage range. It is organized as 512-word×16-bit. It is capable of sequential read, where addresses are automatically incremented in 16-bit blocks. The instruction code is compatible with the NM93C Series.

■ Features

- Low power consumption
Standby : 1 μ A Max.
Operating : 1.2 mA Max. ($V_{CC}=5.5$ V)
 : 0.4 mA Max. ($V_{CC}=2.5$ V)
- Wide operating voltage range
Write : 2.5 to 5.5 V
Read : 1.8 to 5.5 V
- Sequential read capable
- Endurance : 10^5 cycles/word
- Data retention : 10 years

■ Pin Assignment

Figure 1

CS	Chip select input
SK	Serial clock input
DI	Serial data input
DO	Serial data output
GND	Ground (0 V)
V_{CC}	Power supply
TEST	Test pin (normally kept open) (can be connected to GND or V_{CC})

■ Block Diagram

■ Operation

Instructions (in the order of start-bit, instruction, address, and data) are latched to DI in synchronization with the rising edge of SK after CS goes high. A start-bit can only be recognized when the high of DI is latched at the rising edge of SK after changing CS to high, it is impossible for it to be recognized as long as DI is low, even if there are SK pulses after CS goes high. Any SK pulses input while DI is low before receiving a start-bit are called "dummy clocks." The number of clocks transmitted by the serial interface in a CPU and the number of clocks needed for operation of the serial memory IC can be adjusted by inserting several dummy clocks before a start-bit. Instruction finishes when CS goes low, where it must be low between commands during t_{CDS} .

All input, including DI and SK signals, is ignored while CS is low.

1. Read

The READ instruction reads data from a specified address. After A0 is latched at the rising edge of SK, DO output changes from a high-impedance state (Hi-Z) to low level output. 16-bit data is continuously output in synchronization with the rise of SK.

When all of the data (D₁₅ to D₀) in the specified address has been read, addresses are automatically incremented and the data in the next address can be read with the input of another SK clock. Thus, the data over whole area of the memory can be read by continuously inputting SK clocks as long as CS is high.

The last address (A_n ... A₁ A₀ = 1 ... 11) rolls over to the top address (A_n ... A₁ A₀ = 0 ... 00).

Figure 5 Read Timing

2. Write (WRITE, ERASE)

There are two write instructions, WRITE, ERASE. Each automatically begins writing to the non-volatile memory when CS goes low at the completion of the specified clock input.

The write operation is completed in 10 ms (t_{PR} Max.), and the typical write period is less than 5 ms. In the S-29430A Series, it is easy to VERIFY the completion of the write operation in order to minimize the write cycle by setting CS to "H" and checking the DO pin after the write operation begins by setting CS to "L." VERIFY operations to detect changes in the DO output can be executed in succession. One is a change from "L" to "H" with CS="H." The other is a change from "L" to "H" after setting CS to "H" and returning CS to "L" repeatedly.

Because all SK and DI inputs are ignored during the write operation, any input of instruction will also be disregarded. When DO outputs high after completion of the write operation or if it is in the high-impedance state (Hi-Z), the input of instructions is available. Even if the DO pin remains high, it will enter the high-impedance state upon the recognition of a high of DI (start-bit) attached to the rising edge of an SK pulse.

2.1 WRITE

This instruction writes 16-bit data to a specified address.
After changing CS to high, input a start-bit, op-code (WRITE), address, and 16-bit data. If there is a data overflow of more than 16 bits, only the last 16-bits of the data is considered valid. Changing CS to low will start the WRITE operation. It is not necessary to make the data "1" before initiating the WRITE operation.

Figure 6 WRITE Timing

2.2 ERASE

This command erases 16-bit data in a specified address.
After changing CS to high, input a start-bit, op-code (ERASE), and address. It is not necessary to input data. Changing CS to low will start the ERASE operation, which changes every bit of the 16 bit data to "1."

Figure 7 ERASE Timing

3. Write enable (EWEN) and Write disable (EWDS)

The EWEN instruction puts the S-29430A into write enable mode, which accepts WRITE, ERASE instructions. The EWDS instruction puts the S-29430A into write disable mode, which refuses WRITE, ERASE instructions. The S-29430A powers on in write disable mode, which protects data against unexpected, erroneous write operations caused by noise and/or CPU malfunctions. It should be kept in write disable mode except when performing write operations.

Figure 8 EWEN/EWDS Timing

■ Receiving a Start-Bit

A start-bit can be recognized by latching the high level of DI at the rising edge of SK after changing CS to high (Start-Bit Recognition). The write operation begins by inputting the write instruction and setting CS to low. The DO pin then outputs low during the write operation and high at its completion by setting CS to high (Verify Operation). Therefore, only after a write operation, in order to accept the next command by having CS go high, the DO pin is switched from a state of high-impedance to a state of data output; but if it recognizes a start-bit, the DO pin returns to a state of high-impedance (see Figure 9).

Make sure that data output from the CPU does not interfere with the data output from the serial memory IC when you configure a 3-wire interface by connecting DI input pin and DO output pin. Such interference may cause a start-bit fetch problem.

Figure 9 Start bit latching timing

■ Three-wire Interface (DI-DO direct connection)

Although the normal configuration of a serial interface is a 4-wire interface to CS, SK, DI, and DO, a 3-wire interface is also a possibility by connecting DI and DO. However, since there is a possibility that the DO output from the serial memory IC will interfere with the data output from the CPU with a 3-wire interface, install a resistor between DI and DO in order to give preference to data output from the CPU to DI (See Figure 10).
