

AT&T DSP3207 Digital Signal Processor

The Solution for Concurrent Telephony and Audio for PCs

Features and Benefits

Feature	Benefit
66 MHz (60 ns) and 55 MHz (72 ns) operation @ 5 V (also available for 3.3 V operation).	Product offerings range from highest performance to lowest power dissipation.
Microprocessor bus compatibility: <ul style="list-style-type: none">■ 32-bit, byte-addressable address space■ Retry, relinquish/retry, and bus error support■ Page mode DRAM support■ Direct support for both 680x0 and 80x86 signaling	Designed for efficient bus master designs allowing the DSP3207 to be easily incorporated into μ P-based systems. The 32-bit, byte-addressable space enables the DSP3207 and a μ P to share common address space and pointer values as well.
AT&T VCOS [®] operating system: <ul style="list-style-type: none">■ Real-time, multitasking operating system■ Uses host rather than local memory■ True parallel processing■ Complete task management	Open development environment: <ul style="list-style-type: none">■ Dramatically lower system costs.■ Full utilization of both μP and DSP3207.■ Simplifies both algorithm and application development.
Low-power mode during wait for interrupt (<30 mW at 3.3 V) Clock gating pin for extremely low sleep power (<3 mW at 3.3 V)	Designed for systems requiring low power dissipation, especially when the machine is not in operation.
Object code compatible with DSP3210 Plug-in compatible with DSP3210	DSP3210 software investment preserved for DSP3207 designs. DSP3210 designs easily migrated to DSP3207 designs.
Full 32-bit floating-point arithmetic C-like assembly language Single-cycle PC relative addressing	Ease of programming/higher performance.
Instructions started every instruction cycle (four memory accesses per instruction cycle)	Higher performance.

Introduction

The DSP3207 provides a flexible signal processing platform designed especially for personal computers, opening a wide range of multimedia applications. More specifically, the DSP3207 is an optimized version of the DSP3210 that facilitates the integration of telephony and audio into personal computers. With the new I/O requirements of concurrent audio and telephony, a DSP3207-based design can be more flexible and cost-effective by separating the I/O and the signal processing operations.

In addition, particular attention is paid to primary bus interfacing; the DSP3207 is compatible with both i80x86 and 68030/40 microprocessor signaling. This allows designers to easily create low-cost systems using the DSP3207 as a bus-master device.

Introduction (continued)

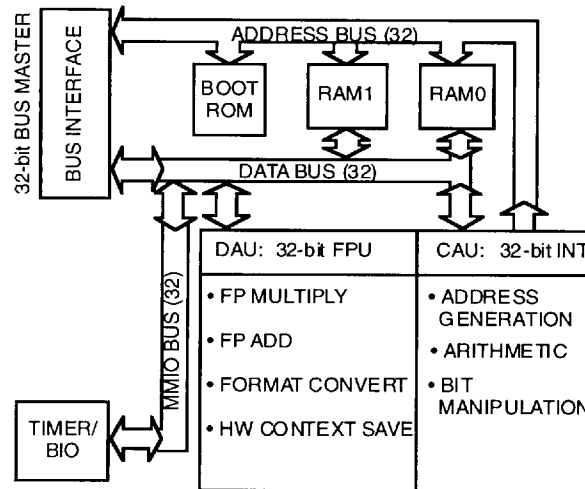

Figure 1. DSP3207 Block Diagram

The DSP3207 is offered in both 5 V and 3.3 V versions. At 5 V, the speed selections are 66 MHz (60 ns instruction cycle time) or 55 MHz (72 ns). For power-conscious systems, designers can take advantage of the 3.3 V DSP3207. For more power saving features, see the Low-Power, Powerdown Mode section.

Along with its optimizing C compiler and assembly-language software tools, the DSP3207 is further supported by AT&T's *VCOS* operating system.

The *VCOS* operating system provides a powerful real-time, multitasking and multiprocessing environment which effectively manages multimedia applications across various computer platforms. By employing innovative task- and code-management techniques, the *VCOS* operating system allows the DSP3207 to use existing system memory in PCs and workstations rather than the usual expensive dedicated SRAM for DSP program and data storage.

Complete real-time debugging tools are included to speed both application and algorithm development. By separating the application and algorithm development phases of multimedia software creation, the *VCOS* environment greatly simplifies and shortens development schedules.

The *VCOS* solution includes its own multimedia library, complete with speech processing, speech recognition, graphics, music processing, and modem modules. The *VCOS* system is an open environment, so application developers may access third-party modules as well as AT&T's library. In addition to new application software, the DSP3207 also has access to the large base of existing DSP32C and DSP3210 application software.

Figure 1 shows the DSP3207 block diagram. Following a brief description of the DSP3207's application in multimedia environments, each functional unit, the instruction set, and the processor control features are described.

This data sheet is designed to be a companion document to the *AT&T DSP3207 Information Manual*. The brief descriptions of the DSP3207's architecture and instruction set in this document are greatly expanded in the information manual. This data sheet is intended to give the latest, up-to-date timing specifications and boot ROM firmware descriptions, while the information manual contains the detailed information needed to understand the DSP3207's operation.

Applications

The DSP3207 may be used in a variety of applications due to its raw floating-point power, low cost, low power dissipation, and interfacing flexibility. However, integrating voice, audio, and telephony in personal computers was the application emphasized when designing the DSP3207.

PC/Workstation Multimedia Applications

DSP3207 Motherboard Implementations

The DSP3207 is intended to be used in PC system architectures in which the DSP3207 is a parallel processor to a host processor. The DSP3207 maintains a 32-bit bus-master interface to system memory (see Figure 2).

The primary benefit of this system architecture is the DSP's ability to access program and data from system memory without host intervention. Furthermore, expensive local SRAM is replaced by the computer's existing system memory.

DSP3207 Add-In Cards

Existing computers with EISA, ISA, MCA, *NuBus*^{*}, SBus, and proprietary bus or CPU direct-slot capabilities can be easily retrofitted with low-cost DSP3207 boards to perform identical applications to motherboard-equipped PCs. In systems with direct CPU slots or 32-bit buses capable of bus mastering, these DSP3207-based cards require no DSP memory (memory is accessed via the bus or CPU direct slot).

Using the visible caching technique native to the *VCOS* operating system, boards installed in lower-bandwidth I/O buses use inexpensive local 32-bit DRAM on the DSP3207 add-in card. In these environments, the DSP3207 uses the computer's I/O bus primarily to transfer tasks and data to and from the DSP3207 card.

^{*} *NuBus* is a registered trademark of Massachusetts Institute of Technology.

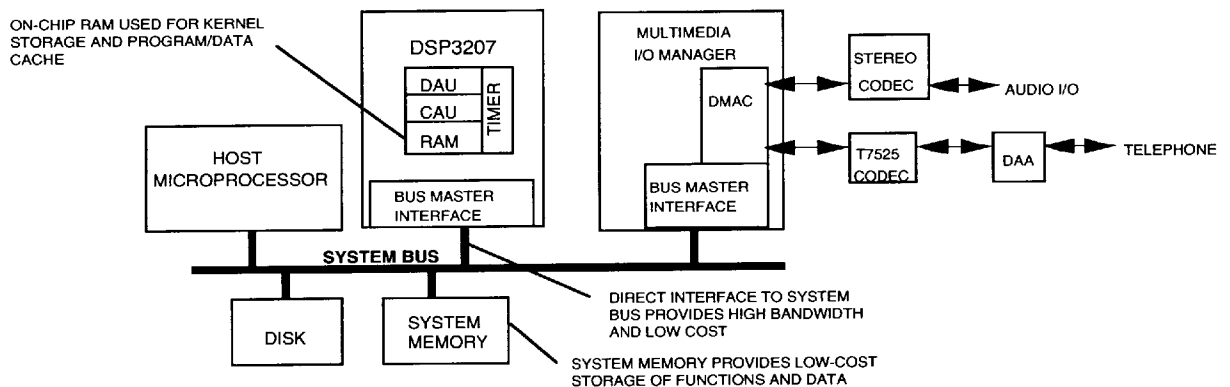

Figure 2. Typical DSP3207 PC/Workstation Motherboard Configuration

Applications (continued)

System Integration Under the VCOS Operating System

Since the DSP3207 supports both big- and little-endian byte ordering, sharing both data and pointer values with any host microprocessor is easily accomplished. This is especially useful in multimedia applications where intimate communications between the host microprocessor and DSP are necessary. For real-time signal processing under the VCOS operating system, on-chip SRAM is loaded with code and data from system memory before executing. Applications are broken into functions that are executed successively in this fashion. Nonreal-time background jobs may either be executed from system memory or cached into the DSP3207's internal memory.

Functional Description

Functional Units

The DSP3207 consists of five functional units: control arithmetic unit (CAU), data arithmetic unit (DAU), on-chip memory (RAM0, RAM1, boot ROM), bus interface, and timer/bit I/O (BIO) unit.

Control Arithmetic Unit (CAU)

The CAU is responsible for performing address calculations, branching control, and 16- or 32-bit integer arithmetic and logic operations. It is a RISC core consisting of a 32-bit arithmetic logic unit (ALU) that performs integer arithmetic and logical operations, a full 32-bit barrel shifter for efficient bit manipulation operations, a 32-bit program counter (PC), and twenty-two 32-bit general-purpose registers.

Figure 3. Control Arithmetic Unit (CAU)

The CAU performs two types of tasks: executing integer, data move, and control instructions (CA instructions), or generating addresses for the operands of floating-point instructions (DA instructions). CA instructions perform load/store, branching control, and 16- and 32-bit integer arithmetic and logical operations. DA instructions can have up to three operand memory accesses per instruction, and the CAU is responsible for generating these addresses using the postmodified, register-indirect addressing mode (one address is generated in each of three states of an instruction cycle).

Data Arithmetic Unit (DAU)

The DAU is the primary execution unit for signal processing algorithms. This unit contains a 32-bit floating-point multiplier, a 40-bit floating-point adder, four 40-bit accumulators, and a control register (dauc). The multiplier and adder work in parallel to perform 16.7 million computations per second, yielding 33 MFLOP performance. The multiplier and adder each produce one floating-point result per instruction cycle. The DAU contains a four-stage pipeline (fetch, multiply, accumulate, write). Thus, in any instruction cycle, the DAU may be processing four different instructions, each in a different stage of execution.

Figure 4. Data Arithmetic Unit (DAU)

The DAU supports two floating-point formats: single precision (32-bit) and extended single precision (40-bit). Extended single precision provides eight additional mantissa guard bits. Postnormalization logic transparently shifts binary points and adjusts exponents to prevent inaccurate rounding of bits when the floating-point numbers are added or multiplied. This eliminates concerns such as scaling and quantization error.

Functional Description (continued)

All normalization is done automatically, so the result in the accumulator is always fully normalized.

Single-instruction, data-type conversions are done in hardware in the DAU, thus reducing overhead required to do these conversions. The DAU performs data-type conversions between the DSP3207 32-bit floating-point format and IEEE P754 standard 32-bit floating-point, 16- and 32-bit integer, 8-bit unsigned, μ -law, and A-law formats. The DAU also provides an instruction to convert a 32-bit floating-point operand to a 3-bit seed value used for reciprocal approximation in division operations.

On-Chip Memory

The DSP3207 provides on-chip memory for instructions and data. Instructions and data can arbitrarily reside in any location in both on- and off-chip memory. The DSP3207 provides two 1K x 32 RAMs and a 256 x 32 boot ROM. The boot ROM is preprogrammed to enable the DSP3207 to boot directly from external memory, such as slow, inexpensive ROM or EPROM.

Bus Interface

The external address bus of the DSP3207 is 32 bits wide and fully byte-addressable, allowing the DSP3207 to directly address 4 Gbytes of memory or memory-mapped hardware. External memory is partitioned into two logical address spaces, A and B. Each partition contains 2 Gbytes of address space.

The number of wait-states for external memory partitions A and B are independently configurable via the **pcw** register. Configured waits of 0, 1, 2, or 3 or more wait-states are programmable; this simplifies the interface to fast external memory. Unlike most digital signal processors (which employ full-cycle wait-states), the DSP3207 offers much greater flexibility. This flexibility is achieved by offering 1/4 cycle wait-states. Each wait-state is 1/4 of an instruction cycle, allowing greater granularity in determining optimal speed/cost memory trade-offs. When waits are externally controlled, the DSP adds wait-states until the memory acknowledges the transaction via the SRDYN pin.

The bus interface supports retry, relinquish/retry, and bus error exception handling. All signaling provided to the external system is configurable on reset to simplify the interface to a variety of microprocessor system buses.

Sharing of the external memory interface is performed via a complete request/acknowledge protocol. System throughput is greatly enhanced by the DSP3207's ability to execute from internal memory while the DSP3207 does not have ownership of the bus.

The DSP3207 will continue to execute from internal memory until accesses to the external memory are needed. At that point, the DSP asserts the BRN signal and waits for BGN. The bus arbiter acknowledges the bus request by asserting the DSP3207's bus grant pin (BGN). The DSP3207, in turn, acknowledges the grant by asserting the bus grant acknowledge (BGACKN) and driving the external memory interface pins. When the BGN is negated, any ongoing external memory transaction is completed before the DSP relinquishes the bus by placing the external memory interface bus in the high-impedance state and negating BGACKN.

Timer/Bit I/O

The timer is a programmable 32-bit interval timer/counter used for interval timing, rate generation, event counting, or waveform generation. The input to the timer can be derived from the DSP3207 clock, or it may come from an external source. The output of the timer can generate a maskable interrupt, or it may be selected as an output of the chip to drive external hardware. It can be configured to count down to zero once or to count continuously by automatically reloading the counter with its initial value when it reaches zero. The count value may be read or changed at any time during operation. The registers associated with the timer are accessible as MMIO registers in the instruction set. By configuring the exception mask register (**emr**), interrupt requests may be generated when the count reaches zero.

Figure 5. Timer/Bit I/O (BIO)

Functional Description (continued)

The BIO is a general-purpose 8-bit input/output port. It includes features that make it suitable for board-level status signal generation and control signal testing by the DSP3207. The BIO interface consists of eight I/O lines, any of which can be independently configured as an input or an output. Outputs can be written with either 1 or 0, toggled, or left unchanged. Inputs can be directly read and loaded into a CAU register and then tested, or the inputs can be read and directly written to memory. The registers associated with the BIO are accessible as registers in the DSP3207 instruction set.

DSP3207 Instruction Set

The assembly language of the DSP3207 frees programmers from tedious memorization of assembly language mnemonics. DSP3207 instructions are patterned after the C programming language and are entered in a natural equation syntax. In addition to being easier to learn, the resulting code is far more readable than mnemonic-based assembly languages, making code maintenance much easier.

C-like assembly language = Easy to learn/excellent readability

Below is an example assembly language instruction:

```
*r1++ = a0 = a1 + *r2++ * *r3++
```

The execution of this instruction simply follows the conventions of the high-level C programming language:

"Multiply the two floating-point values stored in the memory locations pointed to by registers r2 and r3. Add the result to the contents of accumulator a1, store the result in accumulator a0, and write the result to the 32-bit memory location pointed to by register r1. Postincrement pointer registers r1, r2, and r3."

Processor Control Features

The DSP3207 supports advanced control features that simplify system design and improve software performance. This section describes error and interrupt exceptions, and the powerdown mode.

Exception Processing

Normal instruction processing can be altered by the introduction of interrupt routines or error handling routines. Exception processing is the set of activities performed by the processor in preparing to execute a handler routine or in returning to the program that took the exception. Error exception and interrupt exceptions cause different activities to be performed. In particular, error exceptions abort the current instruction and cannot resume processing. Interrupt exceptions shadow the current state of the processor before

taking the interrupt exception; therefore, when the interrupt routine is complete, the program can be reinstated and continued.

The error and interrupt exceptions are prioritized, and some error sources, in addition to all interrupt sources, are individually maskable via the emr. A relocatable vector table controls program flow based on the source of the interrupt exception. In response to a given exception, the DSP branches to the corresponding address in the exception vector table which contains pairs of 32-bit words.

The DSP3207 provides a zero-overhead context save of the entire DAU (floating-point unit) for interrupt processing. Interrupt latency is only two instruction cycles for interrupt entry and one instruction for interrupt exit. Before servicing the interrupt, the DSP3207 automatically saves the state of the machine that is invisible to the programmer, as well as the DAU accumulators a0—a3 (including guard bits), all DAU flag status information, and the dauc register. Internal states that are visible to the programmer are saved and restored by the interrupt service routine. To return to the interrupted program, the interrupt service routine restores the user-visible state of the DSP3207 (that was saved) and then executes the return instruction. This single-cycle interrupt return automatically restores the entire DAU state saved during interrupt entry. Quick interrupt entry/exit/context save is critical to real-time multimedia tasks.

Low-Power, Powerdown Modes

To address the low-power needs of computer platforms, the DSP3207 is equipped with two powerdown modes. One of the modes is implemented with the wait-for-interrupt instruction that stops internal execution in the DAU, CAU, ROM, and RAM sections of the DSP3207. The power consumption in this mode is lowered to less than 30 mW at 3.3 V (120 mW at 5 V). The external memory and internal memory operations execute to completion and then wait. To ensure maximum system functionality, the DSP3207 bus arbitration logic remains active in this mode, and all peripheral units (timer and BIO) remain active to perform I/O events. The interrupt handler is also active to sense interrupt requests. The DSP3207 exits the powerdown mode when either an unmasked interrupt is requested or an error exception occurs. The VCOS operating system takes advantage of this sleep mode feature by placing the DSP3207 in the sleep mode after all tasks have been executed during each frame.

The clock-gating low-power mode is activated by deasserting the CKGN pin, resulting in extremely low power dissipation (<3 mW at 3.3 V, <16 mW at 5 V) by suspending the DSP3207's internal clock. The internal state of the DSP3207 is preserved indefinitely, as well as the state of the output pins. When the clock gating mode is de-activated by asserting CKGN, the internal clock is enabled and the DSP3207 resumes operating from its previous state. For a detailed description of the CKGN pin, refer to the Timing Specifications section.

Boot ROM Code

F02 ac Boot ROM Code

The boot ROM code in DSP3207 devices offers the user three different processor start-up options plus a self-test routine. The processor self-test routine performs a limited functional test of both on-chip RAMs and arithmetic execution units (DAU and CAU). This routine is user-callable as described in the Detailed Description of Self-Test Routine section. The CHECKSUM values, which are located at offset 0x3FC from the beginning of the boot ROM, are unique for each version of the device and can be used as a serial number indicating the exact version of the DSP3207.

Start-Up Options

Since the DSP3207 is intended for a variety of environments, three different start-up options are provided for maximum flexibility. Although the DSP3207 contains an on-chip boot ROM, the first and simplest start-up option doesn't use this ROM. This start-up option works as follows:

- The DSP3207 begins execution at external memory location 0 immediately following reset.

The other two boot options are controlled by the on-chip boot ROM of the DSP3207. These two routines work as follows:

- The DSP3207 loads a 32-bit address from external location 0 and begins executing code at the location indicated by the 32-bit address. This technique, useful in systems where the DSP3207 shares memory with another processor, is known as starting address redirection (SAR).
- The DSP3207 loads and executes instructions from off-chip, byte-wide memory. This technique is frequently used in embedded systems and is known as the EPROM boot routine.

The three start-up options are controlled by bits 10 and 13 of the **pcw** (processor control word) register. In turn, these **pcw** bits are initialized based on the powerup state of external pins connected to bits 7 and 4, respectively, of the DSP3207's bit I/O (BIO) port. Thus, the selection of the start-up routine is based on the powerup status of two signal pins. Details of the three options with a description are given in Table 1. Also, the memory map for DSP3207 is shown in Figure 6.

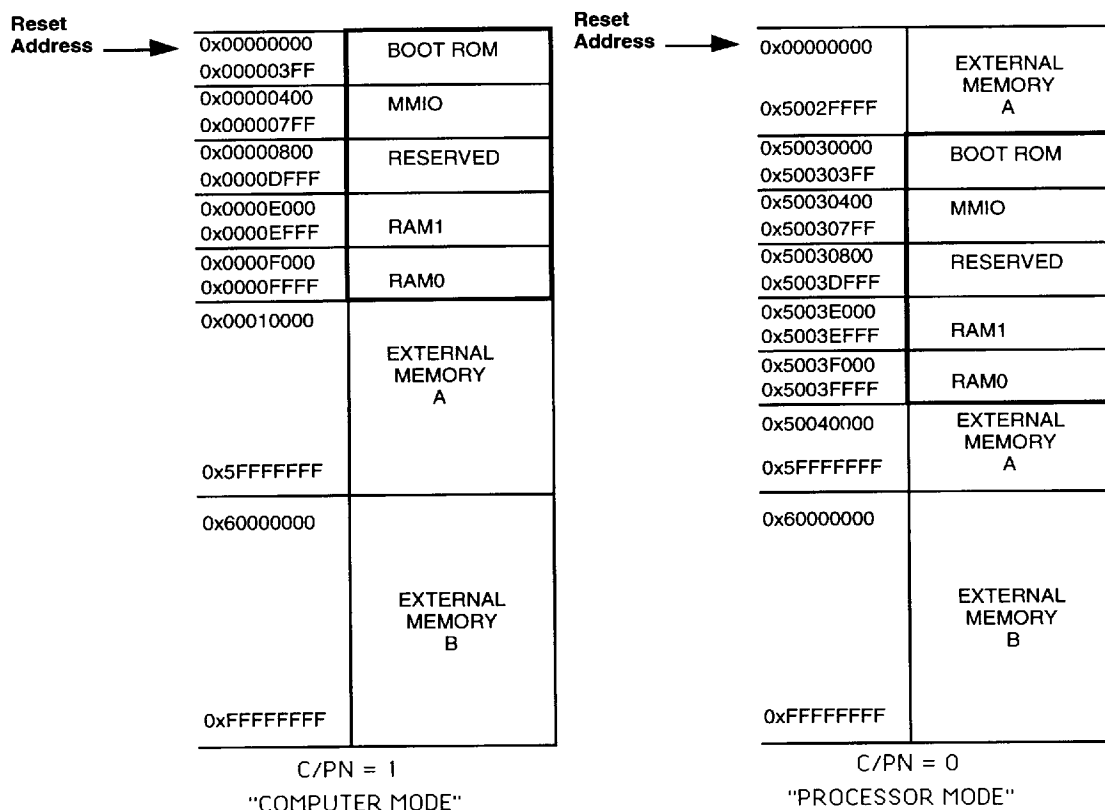

Figure 6. Memory Map

Boot ROM Code (continued)**Table 1. Operation of Boot ROM Routines**

Option	pcw[10]	pcw[13]	Operations
1	0	X (don't care)	Begin execution at external memory location 0 (external memory A) following reset.
2 (SAR)	1	0	<ol style="list-style-type: none"> 1. Interrupt 1 is enabled. 2. Wait-for-interrupt mode is invoked. 3. When interrupt 1 is acknowledged, memory map is changed to processor mode. 4. System host starts the DSP3207; it places a vector to the DSP3207 external memory boot procedure into physical location 0. 5. System host pulses the IREQ1 pin on the DSP3207 and begins polling physical location zero. 6. The DSP3207 acknowledges the interrupt via the IACK1 pin and vectors to location 0x50030078 in the boot ROM. Also location 0 in the external memory is written with a zero. 7. Interrupt 1 is disabled. 8. Prior to return from interrupt, pcsh is loaded from location zero (which is now in external memory) to let the DSP3207 branch to the address supplied by the host processor. 9. The DSP3207 returns from interrupt, which executes a NOP from the shadow instruction register followed by the instruction which was fetched from the vector supplied by the host.
3 (EPROM)	1	1*	<ol style="list-style-type: none"> 1. Read 4 bytes, organized as the least significant byte of the first four word addresses, from external memory starting at 0x60000000 into a 32-bit pointer (this value is known as Address). 2. Read the next 4 bytes, organized as the least significant byte of the next four word addresses, from external memory starting at 0x60000010 into a 32-bit integer (define this as the Count). 3. If Count is zero and Address is nonzero, branch to Address. 4. If Count is nonzero, read Count number of bytes from external memory starting at 0x60000020 and write them to Address to form words and then branch to Address.

* When **pcw**[13] is initialized to 1 via the bio[4] pin, future modification of the **pcw** is **not** disabled. Modification of the **pcw** is disabled only after **pcw**[13] is written with a 1 by a DSP3207 instruction.

Detailed Description of Start-up Boot Routines

Following reset, program execution always begins with the instruction at physical address 0. Physical address 0 will be either in boot ROM or external memory, depending on the state of **pcw** bit 10 (the C/PN bit). This bit selects one of two possible address maps, a computer mode address map or a processor mode address map, thus determining the address of the boot ROM. If C/PN is initialized to a 1 (computer mode), the boot ROM is mapped to begin at physical location 0, and the execution begins from the first location in the boot ROM. If C/PN is initialized to a 0 (processor mode), external memory A is mapped to physical location 0, execution begins there, and the boot ROM is ignored.

Processor Mode Boot

When C/PN = 0, the boot ROM is mapped to address 50030000. The boot ROM code is not executed since execution begins at address 0, which now lies within external memory A. Therefore, the DSP3207

executes code starting from location 0 of its off-chip memory.

Starting Address Redirection (SAR) Boot

When C/PN = 1, execution begins from the boot ROM, which is mapped to address 0. The boot routine tests **pcw** bit 13. If bit 13 = 0, the starting address redirection routine is selected. This is typically used in shared memory systems where a host microprocessor loads the DSP3207 instructions into a shared address space before the DSP3207 begins execution. The microprocessor then passes the starting address to the DSP3207 and signals the DSP3207 to begin execution.

The starting address redirection (SAR) routine begins in computer mode (with the boot ROM beginning at location 0) and ends with the DSP3207 configured in processor mode. The dynamic switching from computer mode to processor mode allows the DSP3207 to execute a start-up routine from boot ROM address 0 and still communicate with a host processor through memory location 0. At the beginning of the

Boot ROM Code (continued)

SAR routine, the DSP3207 sets r22 (also known as exception vector table pointer (**evtp**)) to point to memory location 0x5003000, which will be the address of the first location in boot ROM when the DSP3207 is reconfigured into processor mode (the first 32 word locations in the boot ROM are configured as an exception table). Next, the **emr** register is set to enable external interrupt 1. The DSP3207 then clears **pcw**[10] without changing the other bits in **pcw**. This places the DSP3207 into processor mode which maps external memory to begin at physical address 0.

Finally, the DSP3207 goes into wait-for-interrupt mode with its memory map set for processor mode and the **evtp** pointing to the boot ROM (which now begins at location 0x5003000). Note that the DSP3207 changes its memory map **while entering** the interrupt level. Following the memory map change, the DSP3207 attempts to prefetch an instruction at what was the boot ROM address **boot_error** from **external** memory.

This will appear as address 0xFC on the external address bus. (Recall that the boot ROM is initially mapped to begin at location zero, but external memory A is dynamically mapped to location zero while the DSP3207 enters the interrupt routine.) Even though this fetch is discarded (the contents of external memory at this location are unimportant), **the external system must complete this read transaction** with the DSP3207, or the DSP3207 will hang while waiting to complete this read.

When the system host decides to wake up the DSP3207 (hopefully after it has loaded executable DSP3207 instructions to memory), it places a vector to the starting address of the DSP3207 program at physical location zero. The system host then pulses IREQ1 pin (external interrupt 1 request) on the DSP3207 and begins polling physical location zero. The DSP3207 then clears the EMR register to prevent any further interrupts. The DSP3207 acknowledges the interrupt via the IACK1 pin and vectors to location 0x50030078 in boot ROM. The DSP3207 loads the pc shadow register (**pcsh**) from location zero (now in external memory) to cause the DSP3207 to branch to the address supplied by the host microprocessor when returning from the interrupt routine.

The DSP3207 then performs a return from interrupt instruction (**ireturn**) which executes the *r0 = r0 instruction from the instruction shadow register (which was prefetched while the latent instruction **pcw** = r1 was executed following the waiti instruction). This instruction clears location 0 which signals the host processor that the boot is complete, and the DSP3207 is now executing instructions at the vector location supplied by the host.

Note that if the system is configured for *Intel*^{*}-style signaling, the **pcw** register field M/IN (bit 9) **must** be configured to zero by the DSP3207 program before the DSP3207 attempts to perform byte or 16-bit read and/or write operations. If the system is also

configured for little-endian byte ordering (typically, *Intel*-style systems are also little-endian), the **pcw** register field B/LN (bit 8) should also be set to 0 prior to any byte or 16-bit read and/or write operations (see Chapter 6 of the *DSP3207 Information Manual* for more details on the operation of the DSP3207 external bus interface).

EPROM Boot

When C/PN = 1 and the boot routine test of the **pcw** shows bit 13 = 1, the boot ROM executes a program that boots from an external 8-bit wide memory device, such as an EPROM, and begins execution. This routine is typically used in embedded applications. The EPROM must be 8 bits wide and is mapped to begin at external memory address 0x60000000.

Figure 7 shows the organization of data in the byte-wide EPROM.

The DSP3207 first performs 32-bit reads to eight consecutive 32-bit word locations in the external EPROM, but it only recognizes the data stored in bits 0—7. The least significant byte of the first 4 words makes up the address where the remaining contents of EPROM will be stored and where the DSP3207 will branch to upon completing the boot procedure (Address). During the boot procedure, each word read from external memory contains only 1 byte of information; therefore, four word reads are required to enter 32 bits of information from external memory.

Note the ordering of the bytes which make up each 32-bit word read from external memory; they are read into the DSP3207 with the first byte read occupying the most significant byte of the address word. The least significant bytes of the next four words form a 32-bit word that contains the number of bytes which are to be copied (Count) from the remaining locations into the memory beginning at Address. Again, note that the four bytes of Count are read from external memory, one byte at a time, with first byte read occupying the most significant byte of the Count word.

^{*} *Intel* is a registered trademark of Intel Corporation.

Boot ROM Code (continued)

If Count is 0 and Address is nonzero, the DSP3207 jumps directly to Address and begins execution. If the count is nonzero, the DSP3207 proceeds to load Count number of bytes from EPROM into DSP3207 memory space. Since all DSP3207 executable

instructions are 32-bit words, big-endian byte ordering requires that they be loaded most significant byte first from the boot memory to create valid instructions in the DSP3207's physical memory (see Figure 7). Upon completion of the copy operation, the DSP3207 branches to Address. Note that the memory map remains in the computer mode.

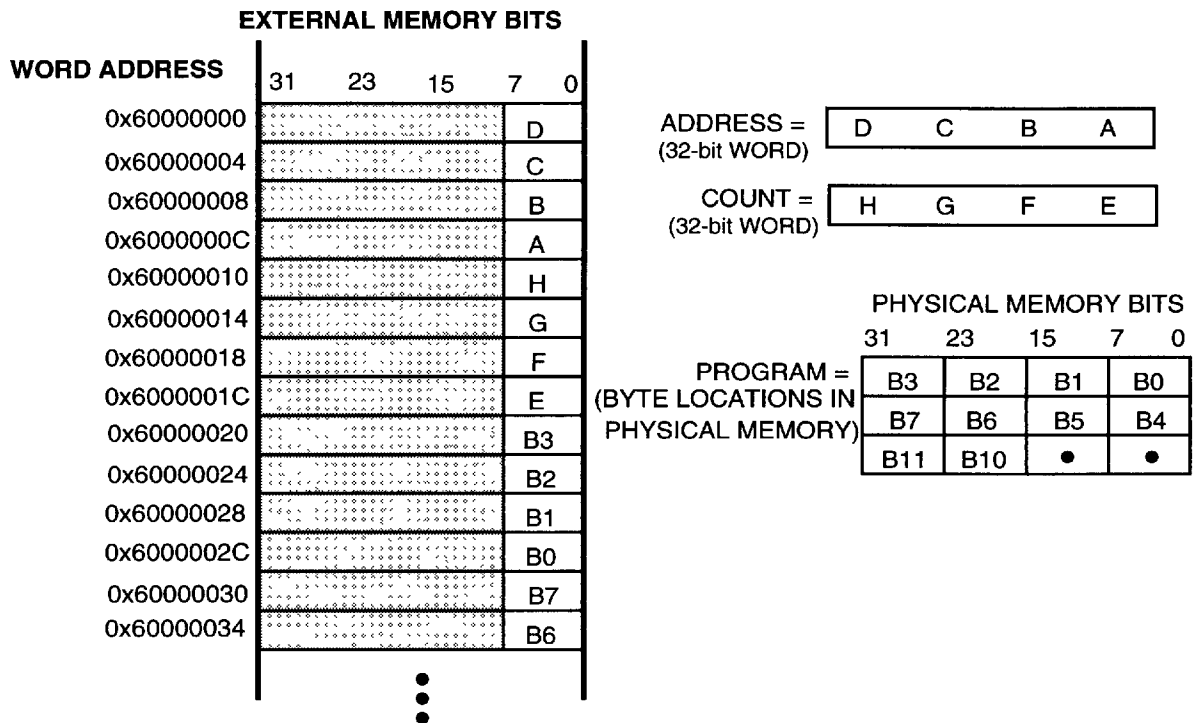

Figure 7. EPROM Data Organization (DSP3207 Begins Execution in Big-Endian Mode)

Boot ROM Code (continued)

Special Note for *Intel*-Style Signaling Implementations (Alternate Loader Routines)

If the external memory of the DSP3207 system is configured in *Intel*-style signaling (with either big- or little-endian byte ordering), transfers directly from EPROM to external memory using the boot ROM procedure will not be correctly executed (since, after reset, the DSP3207 begins executing in the big-endian, *Motorola*-style signaling mode, and the write operation to external memory is a byte operation in the boot ROM program). To correctly load programs and/or data, an alternate loader routine must first be loaded from EPROM to the DSP3207's internal RAM (which is unaffected by the connections to the external memory interface). This alternate loader routine will be loaded into memory as shown in Figure 7.

This program, when executed, should first correctly configure the **pcw** register (bits 8 and 9) and then perform the data move operation from external EPROM to external RAM.

If the system is configured for big-endian byte ordering and *Intel*-style signaling, the read/write routine in the boot ROM listing (following the boot_begin label) can be used in the alternate loader routine. However, *Intel*-style signaling typically uses little-endian byte ordering. If the system is little-endian, the data from the EPROM to be loaded into memory should be ordered B0, B1, B2, B3, B4, B5, . . . to be loaded into physical memory as shown in Figure 7.

Detailed Description of Self-Test Routine

A user-callable self-test routine is included in DSP3207 devices. This routine performs a limited functional test of both on-chip arithmetic execution units (DAU and CAU) and the internal RAMs. During execution, the self-test routine attempts to exercise as many different instruction types as possible.

The self-test routine is located in the boot ROM at location `boot_rom + 0x58`. Recall that the address of the boot ROM within the DSP3207 address map is relocatable, depending upon the C/PN bit in the **pcw** register. If in microcomputer mode (C/PN = 1), `boot_rom` is located at address 0x00000000; if in microprocessor mode (C/PN = 0), `boot_rom` is located at address 0x50030000.

The user invokes the self-test by calling the routine from the user program, with **r1** used as the return address. During self-test execution, all user-visible registers and the internal RAMs are overwritten (except **r1**); therefore, previous register contents are not saved. The self-test routine returns a value of zero in CAU register **r2** if the test was successful. Otherwise, the routine returns a value in **r2** equal to one, indicating failure. The following code sample shows typical usage of the DSP3207 self-test routine:

```
/* Define location of self-test routine using */
/* microprocessor mode (BROM_ADDR should */
/* be defined equal to 0x00000000 if using */
/* microcomputer mode) */

#define BROM_ADDR 0x50030000
#define SELFTEST 0x58

        r10 = (long) BROM_ADDR
        call r10 + SELFTEST (r1)
        nop
        r2 = r0
        if (ne) goto failed /* test r2 contents */
passed:  nop
```

The self-test routine starts by automatically determining its location within the DSP3207 address map, as well as the location of on-chip RAM. It then initializes **r2** to a nonzero value and proceeds to copy the contents of boot ROM to RAM. Registers **a0** and **r17** are cleared for use as checksum registers. Both the DAU and CAU execution units are simultaneously used to compute the arithmetic sum (16-bit values) of the first 256 words in ROM (the length of boot ROM). The total should add to zero; the last value stored in boot ROM (the CHECKSUM value) ensures this. The computed DAU and CAU checksum values are compared at the end of the routine.

Similarly, the CAU is used to perform a 32-bit addition of the entire RAM. The result, which should also equal zero, is tested at the end of the routine. The self-test routine also performs dummy reads of the timer and **dauc** registers to exercise their respective peripheral buses.

Lastly, if the computed checksums yield a zero arithmetic sum (indicating the device passed), a value of zero is stored in **r2**, and program flow branches back to the user via the return address stored in register **r1**.

Absolute Maximum Ratings

Stresses in excess of the Absolute Maximum Ratings can cause permanent damage to the device. These are absolute stress ratings only. Functional operation of the device is not implied at these or any other conditions in excess of those given in the operational sections of the data sheet. Exposure to Absolute Maximum Ratings for extended periods can adversely affect device reliability.

Parameter	Value
Voltage Range on Any Pin with Respect to Ground	−0.5 V to +6 V
Ambient Temperature Range	−40 °C to +120 °C
Storage Temperature Range	−65 °C to +150 °C

Warning: All CMOS devices are prone to latch-up if excessive current is injected to/from the substrate. To prevent latch-up at powerup, no input pin should be subjected to input voltages greater than V_{IL} or less than $V_{SS} - 0.5$ V before V_{DD} is applied. After powerup, input should not be greater than $V_{DD} + 0.5$ V or less than $V_{SS} - 0.5$ V.

Handling Precautions

All MOS devices must be handled with certain precautions to avoid damage due to the accumulation of static charge. **Although input protection circuitry has been incorporated into the devices to minimize the effect of this static buildup, proper precautions should be taken to avoid exposure to electrostatic discharge during handling and mounting.** AT&T employs a human-body model for ESD susceptibility testing. Since the failure voltage of electronic devices is dependent on the current and voltage and, hence, the resistance and capacitance, it is important that standard values be employed to establish a reference by which to compare test data. Values of 100 pF and 1500 Ω are the most common and are the values used in the AT&T human-body model test circuit. The breakdown voltage for the DSP3207 is greater than 1500 V, according to the human-body model. ESD data for the charged-device model is available on request.

Electrical Specifications

The parameters below are valid for the following conditions: $T_A = 0\text{ }^{\circ}\text{C}$ to $70\text{ }^{\circ}\text{C}$ ($T_J \leq 125\text{ }^{\circ}\text{C}$); $V_{DD} = 5\text{ V} \pm 5\%$; $V_{SS} = 0\text{ V}$.

Parameter	Symbol	Min	Max	Unit
Input Voltage except CKI:				
Low	V_{IL}	—	0.8	V
High	V_{IH}	2.0	—	V
Input Voltage for CKI:				
Low	V_{ILC}	—	0.8	V
High	V_{IHC}	2.4	—	V
Output Voltage:				
($I_{OL} = 6\text{ mA}$) Low (TTL)	V_{OL}	—	0.4	V
($I_{OL} = 50\text{ }\mu\text{A}$) Low (CMOS)	V_{OL}	—	0.2	V
($I_{OH} = -2\text{ mA}$) High (TTL)	V_{OH}	2.4	—	V
($I_{OH} = -50\text{ }\mu\text{A}$) High (CMOS)	V_{OH}	$V_{DD} - 0.2$	—	V
Output Current:				
($V_{OL} = 0.4\text{ V}$) Low	I_{OL}	—	6.0	mA
($V_{OH} = 2.4\text{ V}$) High	I_{OH}	-2.0	—	mA
Input Leakage except ZN:				
($V_{IL} = 0\text{ V}$) Low	I_{IL}	-5	—	μA
($V_{IH} = 5.25\text{ V}$) High	I_{IH}	—	5	μA
Input Leakage for ZN:				
($V_{IL} = 0\text{ V}$) Low	I_{IL}	-450	—	μA
($V_{IH} = 5.25\text{ V}$) High	I_{IH}	—	5	μA
Output Hi-Z Current:				
($V_{\text{applied}} = 0.0\text{ V}$) Low	I_{OZL}	-10	—	μA
($V_{\text{applied}} = 5.25\text{ V}$) High	I_{OZH}	—	10	μA
Input, Output, I/O Capacitance	C_i	—	10	pF
55 MHz:				
Power Supply Current* ($V_{DD} = 5.25\text{ V}$, CKI pd = 18 ns)	I_{DD}	—	244	mA
Power Dissipation† ($V_{DD} = 5.25\text{ V}$, CKI pd = 18 ns)	PD	—	1.28	W
66 MHz:				
Power Supply Current* ($V_{DD} = 5.25\text{ V}$, CKI pd = 15 ns)	I_{DD}	—	282	mA
Power Dissipation† ($V_{DD} = 5.25\text{ V}$, CKI pd = 15 ns)	PD	—	1.48	W

* Current in the input buffers is highly dependent on the input voltage level. At full CMOS levels, essentially no dc current is drawn, but for levels near the threshold of 1.4 V, high and unstable levels of current may flow. There are 56 input buffers on the chip. If all inputs are connected to a dc voltage of 1.4 V, an additional current in the range of 100 mA can be drawn.

† The power dissipation listed is for internal power dissipation only. Total power dissipation can be calculated based on the system configuration by adding $C \cdot V_{DD}^2 \cdot f$ for each output, where C is the load capacitance, and f is the output frequency.

Timing Specifications

The characteristics listed are valid under the following conditions: $T_A = 0^\circ\text{C}$ to 70°C ; $V_{DD} = 5\text{ V} \pm 5\%$; $V_{SS} = 0\text{ V}$.

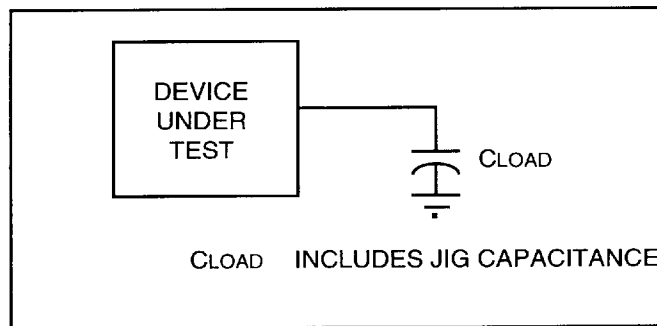

Figure 9. ac Testing Load Circuit

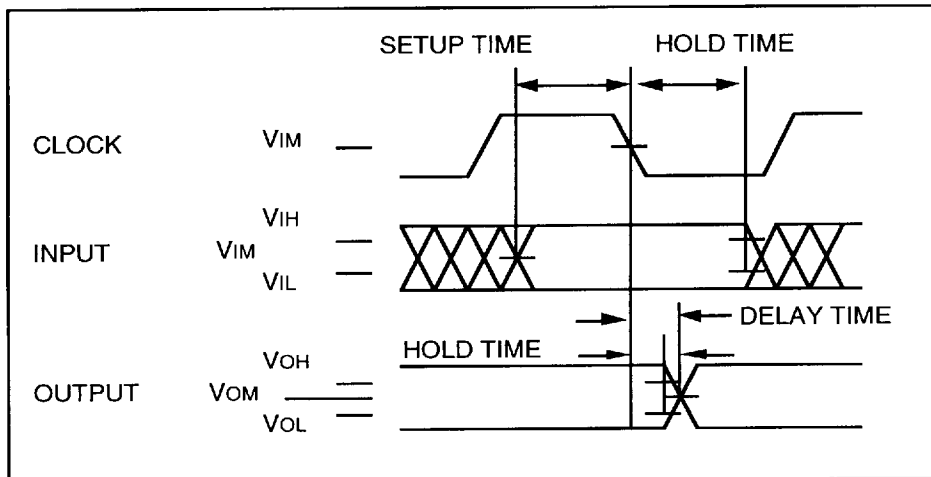

Figure 10. ac Testing Input/Output Waveform

Test conditions for inputs (unless otherwise specified):

- Rise and fall times of 4 ns or less.
- Timing reference level for setup times is $V_{IM} = 1.5\text{ V}$.
- Timing reference levels for hold times are V_{IH} , V_{IL} .

Test conditions for outputs (unless otherwise specified):

- $C_{LOAD} = 50\text{ pF}$ unless otherwise stated.
- Timing reference level for delay times is $V_{OM} = 1.5\text{ V}$.
- Timing reference levels for hold times are V_{OH} , V_{OL} .

Timing Specifications (continued)

Clock Gating Pin

The clock gating pin CKGN is an asynchronous active-low input which enables the DSP3207 input clock (CKI) to propagate throughout the chip. This pin should normally be set low to allow the DSP3207 to function. By setting the pin high, the master internal clock within the DSP3207 will be suspended at a low level. This clock suspension will cause the DSP3207 power consumption to drop below 3 mW at 3.3 V. The suspension of the clock inside the DSP3207 will begin several CKI cycles after CKGN has been raised. When the CKGN pin is reasserted, the internal master clock will resume operation. This will allow the DSP3207 to continue from its suspended point.

Extreme care should be taken when de-asserting CKGN. If the DSP3207 has been granted the bus when CKGN is set high, then the bus output pins will continue to be driven by the DSP3207. Therefore, it is recommended that the DSP3207 be placed in the wait-for-interrupt powerdown mode prior to de-asserting CKGN. This ensures that the DSP3207 will not be granted the bus when its internal clock is suspended. Refer to the *AT&T DSP3207 Information Manual* for further details.

The reset pin (RESTN) overrides the CKGN function. When the RESTN pin is set active-low, the DSP3207 will begin resetting independent of the state of the CKGN pin. When RESTN is de-asserted and the CKGN pin is high, the DSP3207 will then be suspended after several CKI cycles. When the CKGN pin is set active-low, the reset operation will then continue.

Timing Specifications (continued)

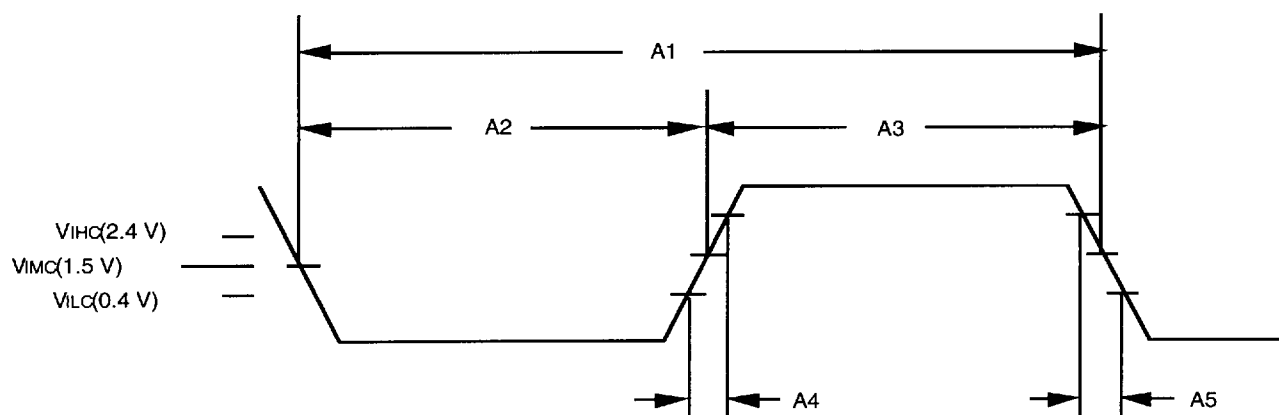

Figure 11. CKI Timing Specifications

Table 3. Timing Requirements for CKI (See Figure 11.)

Num*	Symbol	Parameter	55 MHz		66 MHz		Unit
			Min	Max	Min	Max	
A1	tCKILCKIL	Clock In Period†	18	—‡	15	—‡	ns
A2	tCKILCKIH	Clock In Low	8.1	—	6.75	—	ns
A3	tCKIHCKIL	Clock In High	8.1	—	6.75	—	ns
A4	tCKIRISE	Clock In Rise Time	—	4	—	4	ns
A5	tCKIFALL	Clock In Fall Time	—	4	—	4	ns

* This column in all timing requirements and/or characteristic tables refers to the internal alphanumeric symbol in the timing diagrams.

† tCKILCKIL is referred to as T for specifications that are a function of the period of CKI.

‡ This device is static. However, the maximum period guaranteed by test is 50 ns.

Table 4. Timing Requirements for Synchronous Bus Interface Inputs (See Figures 12 and 14.)

Num	Symbol	Parameter	55 MHz		66 MHz		Unit

D6	tCKILBIOV	BIO Delay	—	15	—	14	ns
D7	tCKILBIOX	BIO Hold	3	—	3	—	ns

Timing Specifications (continued)

Figure 16. Interrupt Timing

Table 13. Timing Requirements for Interrupts (See Figure 16.)

			55 MHz and 66 MHz		Unit
Num	Symbol	Parameter	Min	Max	
E1	tIRLCKIL	Interrupt Asserted Setup Time (synchronous)	4	—	ns
E2	tCKILIRX	Interrupt Asserted Hold Time (synchronous)	2	—	ns
E3	tIRLIRH	Interrupt Asserted Pulse Width (asynchronous)	T + 5	—	ns
E4	tIACKLIRH	Interrupt Acknowledge to Interrupt Negation *	—	2T	ns

* The interrupt request signal must be deasserted within two CKI periods of the interrupt acknowledgement signal's deassertion, in order to prevent a subsequent extraneous interrupt.

Table 14. Timing Characteristics for Interrupts (See Figure 16.)

			55 MHz		66 MHz		Unit
Num	Symbol	Parameter	Min	Max	Min	Max	
E5	tCKILIACKH	Interrupt Acknowledge Delay	—	15	—	14	ns
E6	tCKILIACKX	Interrupt Acknowledge Hold *	3	—	3	—	ns

* The interrupt acknowledge signal will remain asserted until the ireturn instruction is executed.

Timing Specifications (continued)

Figure 17. RESTN Test Load Circuit

Table 15. Timing Requirements for Reset (See Figures 17 to 19.)

Num	Symbol	Parameter	Min	Max	Unit
F1	tBIOVRESTH	BIO Setup to RESTN High* (55 MHz)	8	—	ns
F1	tBIOVRESTH	BIO Setup to RESTN High* (66 MHz)	6	—	ns
F2	tRESTHBIOX	BIO Hold after RESTN High	—	0	ns
F3	tRESTHZNH	ZN High after RESTN High	—	8T†	ns
F4	tRESTLRESTH	RESTN In Pulse Width	8T + 10	—	ns
F5	tRESTLRESTH	RESTN In Pulse Width	8T + 10	—	ns

* Only BIO4—BIO7 are latched into the device when RESTN makes a zero-to-one transition.

† ZN may be asserted at any time. This maximum specification permits correct DSP3207 operation in the run mode.

Table 16. Timing Characteristics for Reset and ZN (See Figures 17 to 19.)

Num	Symbol	Parameter	Min	55 MHz	66 MHz	Unit
				Max	Max	
F6	tRESTPU	Power-on RESTN Output Pulse Width	7T - 10	7T + 60	7T + 60	ns
F7	tCKILRESTV	Power-on RESTN Output Delay	—	60	60	ns
F8	tRESTLBIOZ	Power-on RESTN Low to BIO High Z (inputs)	—	9	9	ns
F9	tRESTLBISZ	Power-on RESTN Low to Bus Interface Signals High Z*	—	9	9	ns
F10	tRESTHBISE	RESTN High to Bus Interface Signals Low Z	—	12T + 18	12T + 15	ns
F11	tRESTLSOBZ	Power-on RESTN Low to Output and Biput Signals High Z†	—	9	9	ns
F12	tRESTLSOBE	Power-on RESTN Low to Output and Biput Signals Low Z	—	8T + 12	8T + 12	ns
F13	tZNLSOBZ	ZN Low to Output and Biput Signals High Z	—	12	9	ns
F14	tZNHSOBE	ZN High to Output and Biput Signals Low Z	—	12	9	ns
F15	tRESTILBIOZ	RESTN In Low to BIO High Z (Inputs)	—	12	9	ns
F16	tRESTILBISZ	RESTN In Low to Bus Interface Signals High Z	—	4T + 18	4T + 15	ns

* Bus interface signals are defined to be A2—A31, MS0—MS3, CSN, ASN, RW, PBD, MRN, MWN, and LOCKN.

† Outputs and biputs are defined to be BRN, BGACKN, BIO0—BIO7, and IACK0—IACK1.
