

500kHz, Serial Input, Programmable Sine Wave Generator with Digital Gain Control

GENERAL DESCRIPTION

The ML2037 is a precision programmable sine wave generator with a frequency range of DC to 500kHz. The device is capable of generating a wide frequency range of low distortion sine waves with no external passive components. The frequency of the sine wave output is programmed by a 16-bit word that is loaded through a serial input. The sine wave output frequency is determined by the programmed value and the clock frequency. The clock frequency is derived from either an external crystal connected to the device or an external clock input to provide a stable and accurate frequency reference.

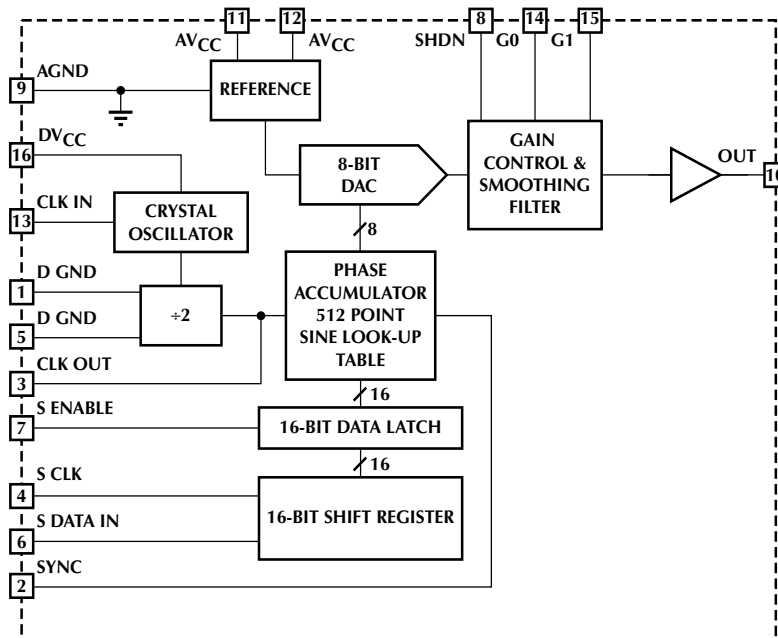

The sine wave output of the ML2037 is filtered and has a programmable amplitude that is digitally programmed in 0.5V steps. The maximum amplitude is 2.0V_{P-P} centered at a 2.5V level. The device functions from a single 5V power supply and has a shutdown pin to put the device into a low power mode that disables the output. A sync input is provided to allow the synchronization of more than one device in a system.

FEATURES

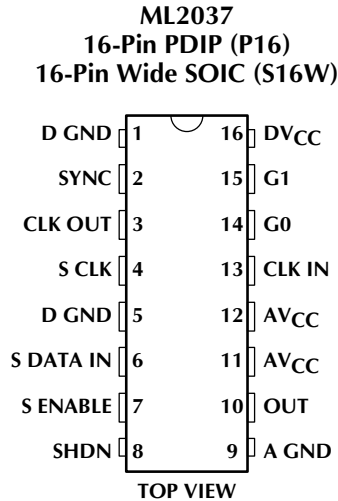

- Programmable output frequency:
DC to 400kHz—using a crystal
DC to 500kHz—using an external digital clock
- 3-wire SPI compatible serial interface with double buffered latch for programming the frequency
- Digital gain control for programming output amplitude
- SYNC input for synchronization of multiple sine waves
- Shutdown pin for sleep mode
- Single 5V power supply operation

* This Part Is End Of Life As Of August 1, 2000

BLOCK DIAGRAM

PIN CONFIGURATION

PIN DESCRIPTION

| PIN | NAME | FUNCTION | PIN | NAME | FUNCTION |
|------|-----------|--|-------|------------------|--|
| 1, 5 | D GND | Ground connection for the digital sections of the IC. | 9 | A GND | Ground reference for analog sections of the IC and reference for OUT. |
| 2 | SYNC | Synchronization input. Holding this pin low stops the sine wave output, and resets the phase to zero. | 10 | OUT | Sine wave output. The amplitude of the sine wave will vary around a 2.5V DC level. |
| 3 | CLK OUT | Output of the internal high frequency clock generator. $f_{CLK\ OUT} = \frac{1}{2}f_{CLK\ IN}$. | 11,12 | AV _{CC} | Power supply for the analog sections of the IC. |
| 4 | S CLK | Serial data clock input. Serial data is clocked into the shift register on falling edges of S CLK. | 13 | CLK IN | Input of the internal high frequency clock generator. This pin is either driven from an external clock input or connected to a crystal for use with the internal oscillator. |
| 6 | S DATA IN | Serial data input for programming the output frequency. | 14 | G0 | Output gain control. Works with G1 to set the output amplitude to one of four different full scale ranges. |
| 7 | S ENABLE | Serial interface enable control. A logic high on this pin allows data to be entered into the latch. | 15 | G1 | Output gain control. Works with G0 to set the output amplitude to one of four different full scale ranges. |
| 8 | SHDN | A logic high on this pin causes the output of the generator to shut off and places the IC in a low power standby mode. | 16 | DV _{CC} | Power supply for the digital sections of the IC. |

ABSOLUTE MAXIMUM RATINGS

Absolute maximum ratings are those values beyond which the device could be permanently damaged. Absolute maximum ratings are stress ratings only and functional device operation is not implied.

AV_{CC} , DV_{CC} 7V
 Voltage on any other pin AGND - 0.3V to AV_{CC} + 0.3V
 Input Current ± 25 mA
 Junction Temperature 150°C
 Storage Temperature Range -65°C to 150°C

Lead Temperature (Soldering, 10 sec) 260°C
 Thermal Resistance (θ_{JA})
 Plastic DIP 80°C/W
 SOIC 105°C/W

OPERATING CONDITIONS

Temperature Range
 ML2037CX 0°C to 70°C
 ML2037IX -40°C to 85°C
 AV_{CC} , DV_{CC} Range 4.75V to 5.25V

ELECTRICAL CHARACTERISTICS

Unless otherwise specified, $AV_{CC} = DV_{CC} = 4.75$ V to 5.25V, SHDN = 0V, CLK IN = 25.6MHz (crystal) or 32MHz (external clock), $C_L = 50$ pF, $R_L = 1$ k Ω , T_A = Operating Temperature Range (Note 1)

| | | $f_{\text{CLK IN}} = 32\text{MHz}$ | | 16 | 20 | mA |
| | | SHDN = 5V | | | 30 | μA |

Note 1: Limits are guaranteed by 100% testing, sampling, or correlation with worst case test conditions.

FUNCTIONAL DESCRIPTION

The ML2037 is composed of a programmable frequency generator, a sine wave generator, a crystal oscillator, and a digital interface. The functional block diagram is shown in Figure 1.

PROGRAMMABLE FREQUENCY GENERATOR

The programmable frequency generator produces a digital output whose frequency is determined by a 16-bit digital word.

The frequency generator is composed of a phase accumulator which is clocked at $f_{CLK\ IN}$. The value stored in the data latch is added to the phase accumulator every two cycles of CLK IN. The frequency of the analog output is equal to the rate at which the accumulator overflows and is given by the following equation:

$$f_{OUT} = \frac{f_{CLKIN} \times (D15 \rightarrow D0)_{DEC}}{2^{22}} \quad (1)$$

Where (D15–D0) is the decimal value of the programming word.

The frequency resolution and the minimum frequency are the same and can be calculated using:

$$\Delta f_{MIN} = \frac{f_{CLKIN}}{2^{22}} \quad (2)$$

When $f_{CLK\ IN} = 25\text{MHz}$, $\Delta f_{MIN} = 5.96\text{Hz}$ ($\pm 2.98\text{Hz}$). Lower output frequencies are obtained by using a lower clock frequency.

The maximum frequency output can be easily calculated with the following equation:

$$f_{OUT(MAX)} = \frac{f_{CLKIN}}{2^6} \quad (3)$$

When $f_{CLK\ IN} = 25\text{MHz}$, $f_{OUT(MAX)} = 391\text{kHz}$. Higher frequencies, up to 500kHz, are obtained by using an external clock, where $25\text{MHz} < f_{CLK\ IN} < 32\text{MHz}$.

Due to the phase quantization nature of the frequency generator, spurious tones can be present in the output in the range of -50dB relative to fundamental. The energy from these tones is included in the signal to noise + distortion specification (SND) given in the electrical table. The frequency of these tones can be very close to the fundamental, and it is not practical to filter them out.

SINEWAVE GENERATOR

The sinewave generator is composed of a sine lookup table, an 8-bit DAC, an output smoothing filter, and an amplifier. The sine lookup table is addressed by the phase accumulator. The DAC is driven by the output of the table and generates a staircase representation of a sine wave.

The output filter smooths the analog output by removing the high frequency sampling components. The resultant voltage on V_{OUT} is a sinusoid with the second and third harmonic distortion components at least 40dB below the fundamental.

The ML2037 has a 2-bit (G1, G0) digital gain control. With the gain input equal to logic 00, the sine wave amplitude is equal to $0.5V_{P-P}$. Incrementing the gain control input increases the output amplitude in 0.5V steps to a maximum of $2.0V_{P-P}$. The output amplitude is accurate to within $\pm 0.5\text{dB}$ over the frequency range.

| G1 | G0 | P-P OUTPUT AMPLITUDE |
|----|----|----------------------|
| 0 | 0 | .5V |
| 0 | 1 | 1.0V |
| 1 | 0 | 1.5V |
| 1 | 1 | 2.0V |

The analog section is designed to operate over a frequency range of DC to 500kHz and is capable of driving $1\text{k}\Omega$, 50pF loads at the maximum amplitude of $2.0V_{P-P}$. The sine wave output is typically centered about a 2.5V DC level, so for a $2V_{P-P}$ sine wave, the output will swing from 1.5V to 3.5V.

CRYSTAL OSCILLATOR

The crystal oscillator generates an accurate reference clock for the programmable frequency generator. The internal clock can be generated with a crystal or external clock.

If a crystal is used, it must be placed between CLK IN and DGND. An on-chip oscillator will then generate the internal clock. No other external components are required. The crystal should be a parallel resonant type with a frequency between 5MHz to 25.6MHz. It should be placed physically as close as possible to CLK IN and DGND, to minimize trace lengths.

The crystal must have the following characteristics:

- Parallel resonant type
- Frequency: 5MHz to 25.6MHz
- Maximum ESR: 120Ω @ 5 to 10MHz, 80Ω @ 10 to 15MHz, and 50Ω @ 15 to 25.6MHz
- Drive level: $500\mu\text{W}$
- Typical load capacitance: 18 - 20pF
- Maximum case capacitance: 7pF

The frequency of oscillation will be a function of the crystal parameters and board capacitance. In general,

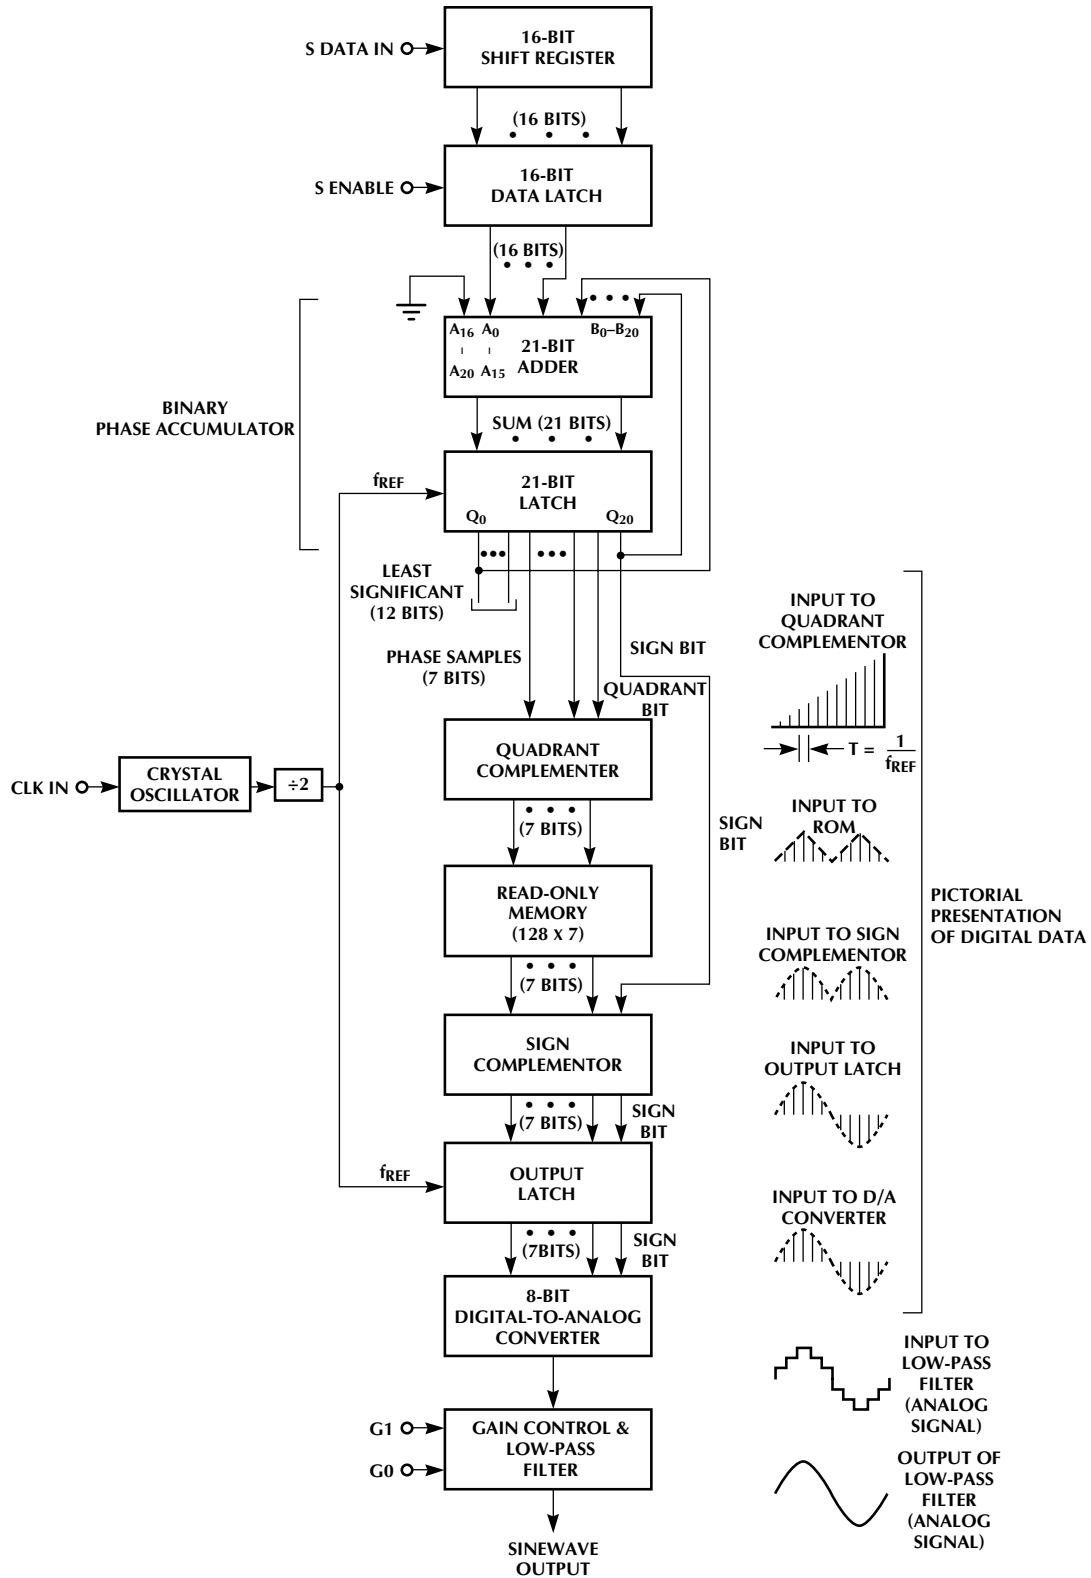

Figure 1. Detailed Block Diagram of the ML2037.

FUNCTIONAL DESCRIPTION (Continued)

microprocessor crystals meet the above requirements, but it is recommended to test the selected crystal in circuit to insure proper operation. Suitable crystals can be purchased from the following suppliers:

ECS, Inc.
FOX Electronics
M-TRON Industries

An external clock can drive CLK IN directly if desired. The frequency of this clock can be anything from 0 to 32MHz. However, at clock frequencies below 5MHz, the sine wave output begins to exhibit "staircasing".

The ML2037 has a clock output that can be used to drive other external devices. The CLK OUT output is a buffered output from the oscillator which runs at one half the frequency of CLK IN.

SERIAL DIGITAL INTERFACE

The digital interface consists of a shift register and data latch. The serial 16-bit data word on S DATA IN is clocked into a 16-bit shift register on falling edges of the serial shift clock, S CLK. The LSB should be shifted in first and the MSB last as shown in Timing Diagram 1. The data that has been shifted into the shift register is loaded into a 16-bit data latch on the falling edge of S ENABLE. To insure that true data is loaded into the data latch from the shift register, the S ENABLE falling edge should occur before the S CLK transitions high to low. S ENABLE should be high while shifting data into the shift register. Note that all data is entered and latched on edges, not levels, of S CLK and S ENABLE.

Upon power up, the data in the latch is indeterminate. It is therefore recommended to initialize the frequency data as part of a power up routine.

SYNCHRONIZATION

When the SYNC pin is held high, the sine wave generator operates normally. Pulling this pin low causes the sine wave output to be interrupted and resets the phase back to zero. The sine wave output goes to the 2.5V DC level approximately 1 μ s after the SYNC input goes low. Switching the SYNC pin back to a high level starts the sine wave going again from zero phase. The delay from when the SYNC goes high to the start of the sine wave is about 500ns, as shown in Figure 2. If several generator chips are driven from the same clock, the SYNC input allows them to be phase synchronized to any value. Figure 3 gives an example of how a microcontroller can be used with two ML2037s to generate two sine waves that are 90° out of phase.

SHUTDOWN

The SHDN input provides a means to power down the analog section and the internal clock of the sine wave generator. When in the power down mode the part will draw only 10 μ A of input current and the output will go to zero approximately 500ns after the SHDN pin goes high. Switching the SHDN back to a low level allows the sine wave to resume at the last programmed frequency. The delay from when the SHDN goes low to when the sine wave resumes is about 200 μ s. The use of the power down mode allows power management for portable applications or for gating the internal oscillator for low noise applications.

POWER SUPPLIES

The analog circuitry in the device is powered from 5V (AV_{CC}) and is referenced to AGND. The digital circuits in the device can also be powered from the same 5V supply (DV_{CC} to DGND). It is recommended that AGND and DGND be connected together close to the device and have a good connection back to the power source.

It is recommended that the power supplies to the device should be bypassed by placing decoupling capacitors from AV_{CC} to AGND and DV_{CC} to DGND as physically close to the device as possible.
