

OVERVIEW

The Σ DECO SM5872A/B D/A converters are high-speed converters for digital audio systems. They are fabricated in Molybdenum-gate CMOS. They incorporate a two-channel, 16-bit D/A converter and a digital eight-times oversampling filter, making them ideal for use in PCM and CD players and digital amplifiers.

The Σ DECO SM5872A/B operate at 32, 44.1 and 48 kHz sampling frequencies and incorporate deemphasis, attenuation and soft mute functions. These functions are controlled either by input pin logic levels or by the microcontroller interface.

The Σ DECO SM5872A/B linearly interpolates the input signal at a high multiple of the original sampling frequency, and then requantizes the resulting signal. A fourth-order noise shaper removes most of the quantizing noise before the signal is output as a pulsewidth-modulated waveform.

The Σ DECO SM5872A/B operate from a 3.2 to 5.5 V supply and are available in 28-pin SOPs and 28-pin shrink DIPs.

FEATURES

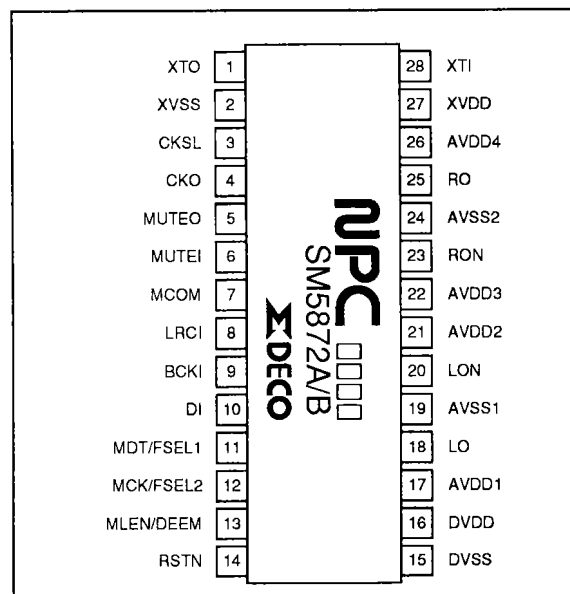

- Two-channel sigma delta D/A converter
- 8-times oversampling FIR filter
 - 69 + 13 + 5 tap, 8fs FIR filter
 - 53 dB stopband attenuation
 - ± 0.05 dB passband ripple
- Fourth-order zero-shift noise shaper
- Digital deemphasis
- 128-step, linear attenuator
- Soft muting
- 13-level, quasi-symmetrical PWM outputs
- Normal- and double-speed operation (SM5872A only)
- On-chip crystal oscillator circuit
- 2s complement, msb-first, 16-bit serial input data format

- Single 5 V supply in normal- and double-speed modes
- Low-voltage operation
 - 3.2 V minimum supply voltage operation in normal-speed mode
 - 4.5 V minimum supply voltage operation in double-speed mode
- Molybdenum-gate CMOS process
- 28-pin SOP and 28-pin shrink DIP

SERIES LINEUP

Device	System clock	Package
SM5872AN	256fs or 512fs (selected using CKSL)	28-pin shrink DIP

SPECIFICATIONS

Absolute Maximum Ratings

$DV_{SS} = AV_{SS} = XV_{SS} = 0 \text{ V}$, $AV_{SS} = AV_{SS1} = AV_{SS2}$, $AV_{DD} = AV_{DD1} = AV_{DD2} = AV_{DD3} = AV_{DD4}$

Parameter	Symbol	Rating	Unit
Supply voltage range	$DV_{DD}, AV_{DD}, XV_{DD}$	-0.3 to 7.0	V
Input voltage range for all inputs except XTI	V_{I1}	$DV_{SS} - 0.3$ to $DV_{DD} + 0.3$	V
XTI input voltage range	V_{I2}	$XV_{SS} - 0.3$ to $XV_{DD} + 0.3$	V
Power dissipation	P_D	250	mW
Storage temperature range	T_{stg}	-40 to 125	deg. C
Soldering temperature	T_{SLD}	255	deg. C
Soldering time	t_{SLD}	10	s

Recommended Operating Conditions

$$DV_{SS} = AV_{SS} = XV_{SS} = 0 \text{ V}, AV_{SS} = AV_{SS1} = AV_{SS2}, AV_{DD} = AV_{DD1} = AV_{DD2} = AV_{DD3} = AV_{DD4}$$

Parameter	Symbol	Rating	Unit
Supply voltage range	DV _{DD} , AV _{DD} , XV _{DD}	3.2 to 5.5	V
Operating temperature range	T _{opr}	-20 to 80	deg. C

Note

All power supply pins (VDD and VSS) must be connected to the same external power supply unit.

AC Analog Characteristics

$DV_{DD} = AV_{DD} = XV_{DD} = 5\text{ V}$, $DV_{SS} = AV_{SS} = XV_{SS} = 0\text{ V}$, $AV_{SS} = AV_{SS1} = AV_{SS2}$,
 $AV_{DD} = AV_{DD1} = AV_{DD2} = AV_{DD3} = AV_{DD4}$, CKSL is HIGH, crystal oscillator operation,
 $f_{OSC} = 22.5792\text{ MHz}$ (SM5872A) or 16.9344 MHz (SM5872B), $T_a = 25\text{ deg. C}$

Parameter	Symbol	Condition	Rating			Unit
			min	typ	max	
Total harmonic distortion and noise	THD + N	$f = 1\text{ kHz}$, $V_i = 0\text{ dB}$	-	0.0020	0.0035	%
Output level	V_{OUT}	$f = 1\text{ kHz}$, $V_i = 0\text{ dB}$	1.8	2.0	2.2	V_{rms}
Dynamic range	D.R	$f = 1\text{ kHz}$, $V_i = -60\text{ dB}$	92	98	-	dB
Signal-to-noise ratio	S/N	$f = 1\text{ kHz}$, $V_i = 0\text{ to }-\infty\text{ dB}$. See note.	96	102	-	dB
Channel separation	Ch. Sep	$f = 1\text{ kHz}$, $V_i = 0\text{ to }-\infty\text{ dB}$	92	98	-	dB

Note

The signal-to-noise ratio (S/N) is measured after reset has been cancelled and with DI held LOW. This includes the noise produced by the noise shaper.

Theoretical Filter Characteristics

The overall frequency characteristics of the IIR filter, and the 32fs sample-and-hold circuit are shown in the following tables and graphs.

Deemphasis disabled

Parameter	Frequency range		Rating			Unit
	f_s	@ $f_s = 44.1\text{ kHz}$	min	typ	max	
Passband ripple	0 to 0.4535	0 to 20.0	-0.05	-	0.05	dB
Attenuation relative to 1 kHz signal	0.4535	20.0	-	-	0.34	dB
Stopband attenuation	0.5465 to 3.45	24.1 to 152	53	-	-	dB
	3.45 to 4.55	152 to 201	32	-	-	
	4.55 to 7.45	201 to 328	70	-	-	

Overall frequency characteristic (Deemphasis OFF)

Transition band characteristic (Deemphasis OFF)

Passband characteristic (Deemphasis OFF)

Passband-only ripple characteristic (Deemphasis OFF)

Deemphasis enabled

Parameter	Sampling frequency, f_s	Passband	Rating			Unit
			min	typ	max	
Deviation from ideal characteristics	44.1 kHz	0 to 19.6 kHz	-0.1	-	0.3	dB
	48.0 kHz	0 to 21.4 kHz	-0.1	-	0.3	dB
	32.0 kHz	0 to 14.0 kHz	-0.4	-	0.6	dB

Note

All frequencies are doubled in double-speed mode.

Overall frequency characteristic (Deemphasis ON)

$f_s = 44.1$ kHz

$f_s = 32.0$ or 48.0 kHz

FUNCTIONAL DESCRIPTION

Functional Block Diagram

The basic arithmetic operation of the Σ DECO SM5872A/B is shown in figure 1.

Figure 1. Arithmetic operation

Oversampling Filter

The oversampling filter comprises three, two-times oversampling filters—a 69-tap finite impulse response (FIR) filter, a 13-tap FIR filter and a 5-tap FIR filter. These filters raise the sample rate of the input signal to 8fs and attenuate quantization noise between 0.5465fs and 7.4535fs. The signal is over-sampled again to either 16fs or 32fs by the sample-and-hold circuit and then input to the zero-shift noise shaper.

Controlling the Built-in Functions

The built-in functions are controlled either by input pin logic levels or by the microcontroller interface as shown in table 1.

Table 1. Built-in functions

Function	Input pin logic level mode (MCOM is LOW)	Microcontroller interface mode (MCOM is HIGH)
Deemphasis ON/OFF	DEEM	FDEEM
Deemphasis fs mode	FSEL1, FSEL2	FFSL1, FFSL2
Attenuator data	No attenuation	7-bit data (a1 to a7)
IIS (64fs BCKI) mode	Not selectable	IIS
BCKI polarity mode	Not selectable	BCPL

Note that the deemphasis functions can be controlled using both methods. The MCOM state and the control mode should not be changed after a reset or power-ON.

Microcontroller Interface

When MCOM is HIGH, MDT, MCK and MLEN function as the microcontroller data clock and latch enable inputs, respectively. Using this interface, an external microcontroller can control the built-in functions and also read the attenuation data and mode flag registers.

The data from the microcontroller input on MDT is latched into the internal shift register on the rising edge of MCK. Changing the state of MDT should, therefore, be done on the falling edge of MCK. The data in the serial-in-parallel-out (SIPO) shift register is latched into either the attenuation data or the mode flag registers on the rising edge of MLEN.

When the first data bit, B1 is LOW, the attenuation data, shown in figure 2, is written to the attenuation data register. When B1 is HIGH, the mode flags, shown in figure 3 and table 2 are written to the mode flag register. Note that MCK and MLEN can have waveforms as shown by the dotted lines in the following two figures.

Figure 2. Attenuation data input

Figure 3. Mode flag data input

Table 2. Mode flags (B1 = HIGH)

Bit	Mode flag	Description	0	1
B2	FFSL1	Deemphasis frequency select bit	See table 3.	
B3	FFSL2			
B4	FDEEM	Deemphasis ON/OFF select	Deemphasis is OFF.	Deemphasis is ON.
B5	IIS	IIS (64fs BCKI) mode select	Normal format data (data at end of channel time, LRCl is HIGH for the left channel.)	IIS format data (64fs BCKI)
B6	BCPL	BCKI polarity select	Data read on rising edge of BCKI.	Data read on falling edge of BCKI.
B7	TEST1	Test mode select	Tie LOW for normal operation.	
B8	TEST2			

Note that all mode flags are LOW after the devices are reset.

Deemphasis Filter

The deemphasis filter is an infinite impulse response (IIR) filter with variable filter coefficients that reproduces the gain and phase characteristics of an analog filter. The filter coefficients can be set to one of three sampling rates as shown in table 3. Deemphasis is turned ON and OFF by DEEM when MCOM is LOW and by the FDEEM flag when MCOM is HIGH.

Table 3. Deemphasis selection

MCOM is LOW.		MCOM is HIGH.		Deemphasis frequency (kHz)
FSEL2	FSEL1	FFSL2	FFSL1	
LOW	LOW	0	0	44.1
LOW	HIGH	0	1	
HIGH	LOW	1	0	48.0
HIGH	HIGH	1	1	32.0

Attenuator

The 7-bit attenuation coefficient data, DATT, is loaded by the SM5872A/B as shown in figure 4.

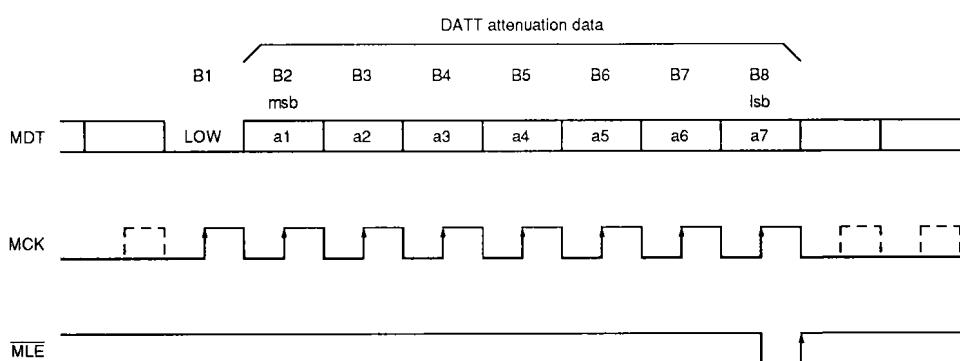

Figure 4. Attenuation data

The output signals are attenuated by multiplying the signal data by the contents of the built-in 7-bit attenuation up/down counter. If the counter value equals the DATT attenuation coefficient, the gain for each channel is given by the following equation.

$$\text{Gain} = 20 \times \log_{10} (1 - \text{DATT}/127) \text{ dB}$$

Both channels are muted completely when the DATT coefficient is 127. Upon reset, DATT is set to zero, corresponding to the maximum gain of 0 dB.

When a new DATT attenuation coefficient is loaded, the gain for each channel ramps up or down to the new level set by the coefficient as shown in

figure 5. If another attenuation coefficient is loaded before this new level has been reached, the gain ramps in the direction of the newest level setting.

The gain can change in this way because the current attenuation level is stored in a different register from the DATT coefficient register.

Figure 5. Attenuation example

Soft mute

When MUTEI is taken HIGH, the soft mute function using the built-in attenuation counter is enabled. The counter increments, decreasing the gain level, until the outputs are completely muted. Muting takes $1024/f_s$ seconds, or approximately 23.2 ms when f_s is 44.1 kHz.

When MUTEI is taken LOW again, muting is cancelled and the attenuation counter decrements, increasing the gain level. Returning to the 0 dB level also takes $1024/f_s$ seconds as shown in figure 6.

Figure 6. Soft muting

System Clock

The system clock can oscillate at 256fs, 384fs or 512fs, depending upon the device, selected by the level on CKSL. When the system clock frequency is 256fs (SM5872A only), double-speed playback is

possible. The normal- and double-speed mode system clock frequencies are shown in the following tables.

SM5872A

Normal-speed mode

$V_{DD} = 3.2$ to 5.5 V, $T_a = -20$ to 70 deg. C

$f_{LRCI} = f_s$ (kHz)	$f_{XTI} = f_{CKO}$ (MHz)	
	CKSL is HIGH.	CKSL is LOW.
44.1	22.5792	11.2896
48.0	24.576	12.288
32.0	16.384	8.192

Double-speed mode

$V_{DD} = 4.5$ to 5.5 V, $T_a = -20$ to 70 deg. C, CKSL is LOW.

$f_{LRCI} = f_s$ (kHz)	$f_{XTI} = f_{CKO}$ (MHz)
88.2	22.5792
96.0	24.576
64.0	16.384

SM5872B

Normal-speed mode

$V_{DD} = 3.2$ to 5.5 V, $T_a = -20$ to 70 deg. C

$f_{LRCI} = f_s$ (kHz)	$f_{XTI} = f_{CKO}$ (MHz)	
	CKSL is HIGH.	CKSL is LOW.
44.1	16.9344	Not used
48.0	18.432	Not used
32.0	12.288	Not used

As the stability and signal-to-noise ratio of the system clock greatly affects the AC analog characteristics, care should be taken to ensure that the clock is free from jitter.

The system clock can be controlled by a crystal oscillator connected as shown in figure 7. Capacitors C1 and C2 should be chosen to match the crystal oscillator.

Figure 7. External crystal oscillator connection

The system clock can also be supplied externally as shown in figure 8. When using this method, XTO should be left open. As the system clock inverter has an internal feedback resistor, the external clock input can be AC coupled.

Figure 8. External system clock connection

To optimize the AC analog characteristics, use an external crystal oscillator connected to a 74HCU04 inverter to drive XTI.

Audio Data Input

The digital audio data is input on DIN in 2s-complement, msb-first, 16-bit serial data format with interleaved left- and right-channel data words.

When the IIS flag is 0, the normal data format shown in figure 9 is selected. When the IIS flag is 1, the IIS data format shown in figure 10 is selected.

The data input on DI is latched into the internal SIPO shift register on either the rising edge of BCKI (when the BCPL flag is 0) or the falling edge (when the BCPL flag is 1).

The data is latched into either the left-channel or right-channel input register on the rising and falling edges of LRCI. When the IIS flag is 0, the data is latched to the left-channel input register on the falling edge of LRCI, and when the IIS flag is 1, the data is latched to the left-channel register on the rising edge of LRCI.

Figure 9. Normal data format (IIS = 0)

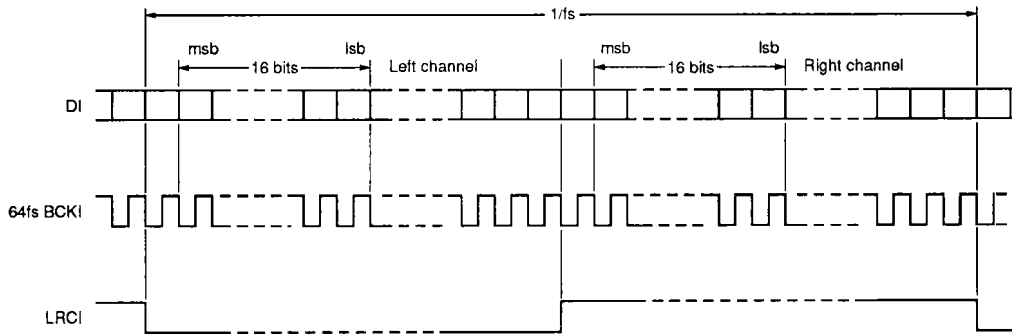

Figure 10. IIS data format (IIS = 1)

The timing of the arithmetic and output circuits is independent of the input circuits, isolating them from jitter or skew on the input circuit clocks. As a result, phase differences between LRCI, BCKI and XTI that may occur after a reset do not affect the correct operation of the device. However, the correct frequency ratio between LRCI and XTI should be maintained.

If the input data format uses word lengths greater than 16 bits (for example, 24- or 32-bit words) then the mute detector will not work unless all bits in the word other than the 16 data bits are set to 0. This condition does not have to be satisfied, however, if MUTE0 is not being used.

Zero-shift Noise Shaper

The fourth-order zero-shift noise shaper (ZSNS) virtually eliminates noise in the 13-level quantized signal by altering the noise characteristic. The characteristic is altered by shifting the zeros in the z-plane, moving the noise out of the audio band so it is then removed by the output filters.

oversampled signal, and over almost the entire audio bandwidth for a 16fs oversampled signal. A theoretical characteristic is shown in figure 11, calculated by converting the data back into its original form, before the PWM output stage. Note that when CKSL is LOW, the frequency values should be halved.

The ZSNS suppresses noise in a frequency range exceeding twice the audio bandwidth for a 32fs

Figure 11. Requantizer noise characteristic

Pulsewidth Modulation Waveforms

The signals output by the Σ DECO SM5872A/B are quasi-symmetrical. When the PWM outputs produce odd-valued output levels, the individual output signals are not symmetrical about the center of the output pulses, however, the difference signals (LO

- LON) and (RO - RON) are symmetrical as shown in figure 12. Even-valued output signals have symmetrical waveforms. Using this output method, the SM5872A/B can operate at half the clock frequency required by conventional devices.

Figure 12. Pulsewidth modulation waveforms

Reset

The Σ DECO SM5872A/B should be reset after power-up, when MCOM changes state or when the XTI clock stops for longer than 10 μ s. A LOW-level pulse on RSTN will resynchronize the

Σ DECO SM5872A/B internal arithmetic and output clocks on the first rising edge of LRCI after RSTN returns HIGH as shown in 13.

Figure 13. Reset waveforms

An external microcontroller can reset the devices at power-ON, or power-ON reset can be performed automatically if a capacitor is connected between RSTN and VSS. If the XTI and LRCI clocks are stable at power-up, then a value of 300 pF is sufficient to satisfy the reset timing requirements. If the XTI and LRCI clocks are not stable at power-up, then a value should be chosen such that RSTN goes HIGH only after both clocks have stabilized.

Upon reset, the PWM outputs are muted with a 50% duty cycle signal from the time when RSTN goes LOW until the 12th rising edge of LRCI after RSTN goes HIGH. Note that the duty cycle may change temporarily as the circuits resynchronize following the first rising edge of LRCI.

Mute Detection

MUTE0 is LOW under the following three conditions.

1. While RSTN is LOW and for approximately 12 LRCI cycles after RSTN goes HIGH.
2. For approximately 12 LRCI cycles after CKSL changes state.
3. While a muted signal is detected as explained in the following paragraphs.

Note that the mute detector detects when the data bits are all 0 and does not detect when the bits are all 1.

The mute detector monitors the BCKI, DI and LRCI inputs. DI should be LOW when not transmitting data if there are more BCKI pulses than there are data bits as shown in figure 14.

Figure 14. Input waveforms

When both channels contain zeros for 2^{19} consecutive BCKI cycles, the internal counter overflows and MUTE0 goes HIGH. When a 1 is input on DI, the counter is reset and MUTE0 goes LOW again.

The time to overflow the counter can be calculated using the following equation.

$$t_z = 2^{19}/(NB \times fs)$$

where NB = the number of BCKI cycles per LRCI period (typically 32 or 48).

Figure 15. MUTE0 output waveforms

For a 44.1 kHz sampling rate and 32 BCKI pulses per sampling period, 2^{19} bits corresponds to a mute detect time of 372 ms. When there are 48 BCKI pulses per sampling period, the mute detect time becomes 248 ms as shown in table 4.

Table 4. Mute detect time

Bit clock frequency	Mute detect time	Unit
32fs	372	ms
48fs	248	ms

Note

fs = 44.1 kHz
