HMCAD5831LP9BE

v00.0312

26 GS/S 3-BIT ANALOG-TO-DIGITAL CONVERTER W/ OVERRANGE, INHIBIT, AND 1:2 DEMUX

Typical Applications

The HMCAD5831LP9BE is ideal for:

• Serial Data Links

• Test Equipment for Link Diagnostics

• Clock & Data Recovery

• Spectrometers

• Ultra Wideband Phased Arrays

• Radio Astronomy

Functional Diagram
General Description

The HMCAD5831LP9BE is a wideband 3-bit analog-to-digital converter with over/under range bit. The converter operates at speeds up to 26 GS/s with a Nyquist input. Reference ladder end voltages are set externally by the user allowing the user to customize input common mode and swing levels. ADC outputs can be forced to 0 by using the Data Inhibit function. Output data can be modulated by an external clock via the XOR CML input. The HMCAD5831LP9BE also features a 1:2 demux with half rate clock output. The output bits are binary weighted, where X2 and Y2 are the MSBs. The single-ended RF input can be AC or DC coupled and supports broadband operation.

The HMCAD5831LP9BE operates from -5 V and -3.3 V supplies and is available in ROHS-compliant 9 x 9 mm SMT package.

Electrical Specifications, T_A = +25 °C, AVEE = -5 V, OVEE = -3.3 V

Reference Ladder

The ADC's voltage reference ladder comprises 8, 18 Ω resistors, or 144 Ω total resistance. Pin 1, RTF, and pin 15, RBF, are provided for the top and bottom reference taps. These pins are driven by external supplies to establish the desired full-scale range of the ADC. The RF signal input (pin 8, IN) to the ADC drives an internal emitter follower with a nominal VBE of -900 mV. Hence the center of full-scale range should center near -900 mV. The voltage at pin RTF is then -900 mV + $V_{full-scale}$/2. Likewise the voltage at pin RBF is -900 mV - $V_{full-scale}$/2.

As an example, if the user had a peak-to-peak input voltage swing of 256 mV and required the full-scale input range of the ADC to be 256 mV as well, RTF would be -900 mV + 128 mV = -772 mV. RBF would be -900 mV - 128 mV = -1.028 V. Note that the diode drop, -900 mV, is dependent on temperature and process variations.

RTF and RBF values in the "Electrical Specifications" table on pages 1 and 2 are shown as nominal values only. Note that ladder end voltages, RTF and RBF, are set by the common-mode level of the input, IN.

For operation of 10 GHz input and 20 GS/s sample rate, recommended maximum input swing is 0.512 V as set by RTF and RBF. For lower input frequencies, the device will operate with a maximum 1.5 V input swing. The Electrical Specifications table lists typical operating ranges.

VREF Pins

Pins 26 and 55 (VREF1 amd VREF2) should be connected together off chip and the pair is then connected to the OGND through a resistor. These pins are used to vary the output swing voltage. The Application Circuit shown uses a 200 Ω resistor. This provides the typical output swings listed in the Electrical Specifications table. Increasing the voltage on VREF1 and VREF2 will increase the output swing. Conversely, decreasing the VREF1 and VREF2 voltages will decrease the output swing.

Overrange Output

Pins 28, 29, 31, and 32 provide overrange output bits. This function indicates when the input signal is out of range of the reference ladder voltages. The bit will be high when either the signal is above RTF or below RBF. The overrange bit is cleared for the next clock cycle containing in-range data.

Data Inhibit

All data outputs can be forced to "0" by enabling the Data Inhibit function (pins 61 and 62). By driving the QTP pin high and the QTN pin low, the ADC core will produce all 0s. This occurs prior to the XOR funciton and the demux. When QTP is low and QTN is high, the chip operates normally.

Data XOR

All data outputs from the ADC core can be modulated by an external source. This allows the user to use AC coupling for output line connection to a SERDES input of an FPGA. This function occurs prior to the demux. The XOR input signal is retimed by the full rate internal clock and requires low jitter and suitable rise and fall times. Please contact Hittite Microwave for sample driver circuits. Typical modulation frequencies are 100 MHz to 300 MHz. For a square wave signal, a multiple of two divisor of the full rate internal clock should be used, e.g. 1/128th or 1/64th of the ADC clock. Due to the nature of the retiming scheme, the demux channel relationship timing can vary. This is dependent on when the XOR input is sampled relative to the full rate internal clock. See timing diagrams on page 5. For example, a nominal setup may have demux side X leading and side Y trailing. If the XOR input is shifted relative to the internal clock, side Y may lead and side X may trail. It is highly recommended that a variable delay be used to adjust the phase of the XOR input to avoid transitions that are very close to internal clock edges. See Typical Operation Example for more information. The XOR function can be used with the Data Inhibit function to produce a sync pattern for aligning the lanes of SERDES inputs. The device outputs are inverted when XOR is low.

Evaluation Board Description

EVAL01-HMC5831LP9 (131499) demonstrates the HMCAD5831LP9BE in an environment ready to be connected to an FPGA. Along with the ADC, the board features three other Hittite Microwave components. The clock output of the ADC is divided down by 64 (two stages of 8, U1, and U2) to produce a clock ouput that is 1/128th of the ADC clock input. This clock is available to drive the FPGA or other system components. The ADC XOR input has programmable delay (U4) allowing the user to fine-tune the XOR clock edges going into the ADC. The INHIBIT and D8BX inputs are 0 to +3.3 V, compatible with most FPGAs. Finally, the ADC_VR pin allows the user to control the output voltage swing of the ADC. Output connectors J2 and J3 are high-performance SAMTEC connectors, part number ERF8-013-05.0-DV.

Ten-Level Operation

The HMCAD5831LP9BE can be used as a ten-level (3.32 bits) ADC by combining the regular data outputs with the Overrange Bit. The bottom code (code 0) is equal to OVR high and all the bits low. For codes 1 through 8, the ADC functions normally (with OVR low). The top code, code 9, is all bits high. Note that the INL/DNL plots include OVR in this manner.

Typical Operation Example

An FPGA with suitably fast SERDES inputs can capture data from the HMCAD5831LP9BE using the following routine. The FPGA produces an INHIBIT high signal causing the ADC core to produce all 0s. The XOR input to the ADC runs at some slow clock rate and modulates the ADC output to produce a known waveform at the FPGA inputs. The FPGA then uses these signals to align the lanes. When the lanes are aligned, the INHIBIT signal goes low and the ADC produces signal data that continues to be modulated by the XOR input. The FPGA then corrects for the modulation. Note that the FPGA can generate the XOR modulation signal (in which case a PRBS sequence could be used). Depending on the phase of the XOR input modulation waveform, either demux output (X or Y) can be the leading data sample. In this case, the FPGA would need to resolve which lane is the leader. This can be accomplished by driving the ADC with a known signal, evaluating the outputs and reassembling FPGA data if necessary. It is recommended to do this on each power up. It is also recommended to perform a routine to ensure that the XOR input waveform is properly aligned with the internal clock. This can be accomplished by sweeping the external variable delay stage.

High-Temperature Operation

It is highly recommended that the part be used with a heat sink and fan. Performance diminishes as temperature increases. Nominal conditions for part evaluation occurred at an ambient temperature of 25 °C. The evaluation board has a heat sink with an area of 25 cm^2. With this setup, the paddle of the part was measured to be 45 °C. When the paddle temperature was raised to 75 °C, limited performance was maintained, with an increased clock power level. At 75 °C, performance is guaranteed up to 10 GHz input frequency, 20 GS/s clock rate only. For temperatures above 75 °C, device performance is not guaranteed above 20 GS/s.

[2] Circuit Board Material: Arlon 25FR or Rogers 4350

The circuit board used in the application should use RF circuit design techniques. Signal lines should have 50 ohm impedance while the package ground leads should be connected directly to the ground plane similar to that shown. The exposed metal package base must be connected to AVEE. A sufficient number of via holes should be used to connect the top and bottom ground planes. The evaluation circuit board shown is available from Hittite upon request.
