

## ■ FEATURES

- Wide  $V_{CC}$  low operation voltage :
  - C-grade : 1.8V ~ 3.6V
  - I-grade : 1.9V ~ 3.6V
- Ultra low power consumption :
 

$V_{CC} = 2.0V$	Operation current : 10mA (Max.) at 85ns
	1mA (Max.) at 1MHz
	Standby current : 2/3uA (Max.) at 70/85°C

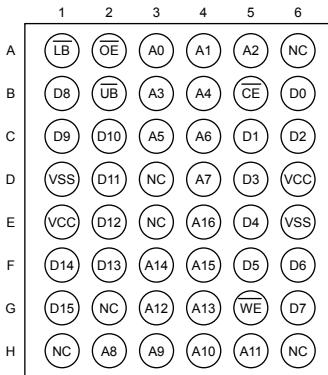

$V_{CC} = 3.0V$	Operation current : 13mA (Max.) at 85ns
	2mA (Max.) at 1MHz
	Standby current : 3/5uA (Max.) at 70/85°C
- High speed access time :
 

-85	85ns (Max.)
-10	100ns (Max.)
- Automatic power down when chip is deselected
- Easy expansion with CE and OE options
- I/O Configuration x8/x16 selectable by LB and UB pin.
- Three state outputs and TTL compatible
- Fully static operation
- Data retention supply voltage as low as 1.5V

## ■ DESCRIPTION

The BS616UV2019 is a high performance, ultra low power CMOS Static Random Access Memory organized as 131,072 by 16 bits and operates from a wide range of 1.8V to 3.6V supply voltage.

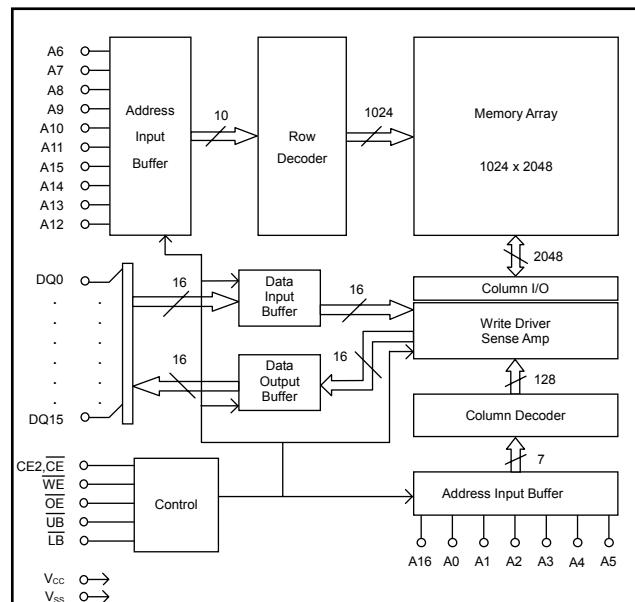

Advanced CMOS technology and circuit techniques provide both high speed and low power features with maximum CMOS standby current of 3/5uA at  $V_{CC}=2/3V$  at 85°C and maximum access time of 85/100ns.

Easy memory expansion is provided by an active LOW chip enable (CE) and active LOW output enable (OE) and three-state output drivers.

The BS616UV2019 has an automatic power down feature, reducing the power consumption significantly when chip is deselected.

The BS616UV2019 is available in DICE form, JEDEC standard 48-pin TSOP Type I package and 48-ball BGA package.

## ■ PIN DESCRIPTIONS

Name	Function
<b>A0-A16 Address Input</b>	These 17 address inputs select one of the 262,144 x 16 bit in the RAM
<b>CE Chip Enable 1 Input CE2 Chip Enable 2 Input</b>	$\overline{CE}$ is active LOW and $\overline{CE2}$ is active HIGH. Both chip enables must be active when data read from or write to the device. If either chip enable is not active, the device is deselected and is in standby power mode. The DQ pins will be in the high impedance state when the device is deselected. (48B BGA ignore $\overline{CE2}$ pin)
<b>WE Write Enable Input</b>	The write enable input is active LOW and controls read and write operations. With the chip selected, when $\overline{WE}$ is HIGH and $\overline{OE}$ is LOW, output data will be present on the DQ pins; when $\overline{WE}$ is LOW, the data present on the DQ pins will be written into the selected memory location.
<b>OE Output Enable Input</b>	The output enable input is active LOW. If the output enable is active while the chip is selected and the write enable is inactive, data will be present on the DQ pins and they will be enabled. The DQ pins will be in the high impedance state when $\overline{OE}$ is inactive.
<b>LB and UB Data Byte Control Input</b>	Lower byte and upper byte data input/output control pins.
<b>DQ0-DQ15 Data Input/Output Ports</b>	16 bi-directional ports are used to read data from or write data into the RAM.
<b>V<sub>cc</sub></b>	Power Supply
<b>V<sub>ss</sub></b>	Ground

**■ SWITCHING WAVEFORMS (WRITE CYCLE)**
WRITE CYCLE 1<sup>(1)</sup>

**WRITE CYCLE 2** <sup>(1,6)</sup>

**NOTES:**

1. WE must be high during address transitions.
  2. The internal write time of the memory is defined by the overlap of CE and CE2 active and WE low. All signals must be active to initiate a write and any one signal can terminate a write by going inactive. The data input setup and hold timing should be referenced to the second transition edge of the signal that terminates the write.
  3. t<sub>wrz</sub> is measured from the earlier of CE or WE going high or CE2 going low at the end of write cycle.
  4. During this period, DQ pins are in the output state so that the input signals of opposite phase to the outputs must not be applied.
  5. If the CE low transition or the CE2 high transition occurs simultaneously with the WE low transitions or after the WE transition, output remain in a high impedance state.
  6. OE is continuously low (OE = V<sub>IL</sub>).
  7. D<sub>OUT</sub> is the same phase of write data of this write cycle.
  8. D<sub>OUT</sub> is the read data of next address.
  9. If CE is low and CE2 is high during this period, DQ pins are in the output state. Then the data input signals of opposite phase to the outputs must not be applied to them.
  10. Transition is measured  $\pm 500\text{mV}$  from steady state with C<sub>L</sub> = 5pF.
- The parameter is guaranteed but not 100% tested.
11. t<sub>cew</sub> is measured from the later of CE going low or CE2 going high to the end of write.
12. 48B BGA ignore this parameters related to CE2.
