# 5 Volt Only Driver/Receiver with an Integrated Standby Mode EIA-232-E and CCITT V.28

The MC145705/06/07 are a series of silicon–gate CMOS transceiver ICs that fulfill the electrical specifications of EIA–232–E and CCITT V.28 while operating from a single + 5 V power supply. These transceiver series are high performance and low power consumption devices that are equipped with standby and output enable function.

A voltage doubler and inverter convert the  $\pm$  5 V to  $\pm$  10 V. This is accomplished through an on-board 20 kHz oscillator and four inexpensive external electrolytic capacitors.

The MC145705 is composed of two drivers and three receivers, the MC145706 has three drivers and two receivers, and the MC145707 has three drivers and three receivers. These drivers and receivers are virtually identical to those of the MC145407.

#### Available Driver/Receiver Combinations

Device	Drivers	Receivers	No. of Pins
MC145705	2	3	20
MC145706	3	2	20
MC145707	3	3	24

#### Drivers:

- ± 7.5 Output Swing
- 300 Ω Power-Off Impedance
- · Output Current Limiting
- · TTL and CMOS Compatible Inputs
- Three-State Outputs During Standby Mode
- Hold Output OFF (MARK) State by TxEN Pin

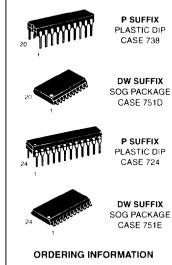

#### Receivers:

- ± 25 V Input Range
- 3 to 7 kΩ Input Impedance
- 0.8 V Hysteresis for Enhanced Noise Immunity
- · Three-State Outputs During Standby Mode

#### Charge Pumps:

- ullet + 5 to  $\pm$  10 V Dual Charge Pump Architecture
- Supply Outputs Capable of Driving Three Drivers on the MC145403/06 Simultaneously
- Requires Four Inexpensive Electrolytic Capacitors
- On-Chip 20 kHz Oscillators

DC Current per F	Pin	I	± 100	mA
Power Dissipatio	n	PD	1	w
Operating Tempe	erature Range	TA	- 40 to + 85	,,C
Storage Tempera	ature Range	T <sub>stg</sub>	- 85 to + 150	'C

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, it is recommended that the voltage at the DI and DO pins be constrained to the range  $\text{GND} \leq \text{V}_{DI} \leq \text{V}_{DD}$  and  $\text{GND} \leq \text{V}_{DO} \leq \text{V}_{CC}$ . Also, the voltage at the Rx pin should be constrained to  $(\text{VSS}-15\ \text{V}) \leq \text{V}_{Rx1}-\text{Rx3} \leq (\text{V}_{DD}+15\ \text{V})$ , and Tx should be constrained to VSS  $\leq \text{V}_{Tx1}-\text{Tx3} \leq \text{V}_{DD}$ .

Unused inputs must always be tied to an appropriate logic voltage level (e.g., GND or V<sub>CC</sub> for DI, and GND for Rx).

#### RECOMMENDED OPERATING LIMITS

Parameter	Symbol	Min	Тур	Max	Unit
Power Supply	Vcc	4.5	5	5.5	٧
Operating Temperature Range	TΑ	- 40	_	85	C

<sup>\*\*</sup> Specification is for one Tx output to be shorted at a time. Should all three driver outputs be shorted simultaneously, device power dissipation limits could be exceeded.

<sup>\*\*\*</sup>This condition could exceed package limitations.

#### PIN DESCRIPTIONS

#### Vcc

#### Digital Power Supply

This digital supply pin is connected to the logic power supply. This pin should have a 0.33 uF capacitor to ground.

# GND

#### Ground

Ground return pin is typically connected to the signal ground pin of the EIA-232-D connector (Pin 7) as well as to the logic power supply ground.

#### Positive Power Supply

This is the positive output of the on-chip voltage doubler and the positive power supply input of the driver/receiver sections of the device. This pin requires an external storage capacitor to filter the 50% duty cycle voltage generated by the charge pump.

#### Vss

#### **Negative Power Supply**

This is the negative output of the on-chip voltage doubler/ inverter and the negative power supply input of the driver/ receiver sections of the device. This pin requires an external storage capacitor to filter the 50% duty cycle voltage generated by the charge pump.

#### TyFN

#### **Output Enable**

This is the driver output enable pin. When this pin is in logic low level, the condition of the driver outputs (Tx1 - Tx3)are in keep OFF (mark) state.

# Standby

DRIVER

The device enters the standby mode while this pin is connected to the logic high level. During the standby mode, driver and receiver output pins become high impedance state. In this condition, supply current Icc is below 10 µA (Typ) and can be operated with low current consumption.

#### C2+, C2-, C1+, C1-

#### Voltage Doubler and Inverter

These are the connections to the internal voltage doubler and inverter, which generate the VDD and VSS voltages.

#### Rx1. Rx2 (Rx3) Receive Data Input

These are the EIA-232-E receive signal inputs. A voltage between + 3 and + 25 V is decoded as a space, and causes the corresponding DO pin to swing to ground (0 V). A voltage hetween - 3 and - 25 V is decoded as a mark, and causes the DO pin to swing up to VCC.

#### DO1, DO2 (DO3) Data Output

These are the receiver digital output pins, which swing from VCC to GND. Each output pin is capable of driving one LSTTL input load.

Output level of these pins is high impedance while in standby mode.

# DI1, DI2 (DI3)

#### **Data Input**

These are the high impedance digital input pins to the drivers. Input voltage levels on these pins must be between VCC and GND.

The level of these input pins are TTL/CMOS compatible.

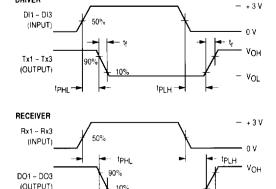

#### Tx1, Tx2 (Tx3) **Transmit Data Output**

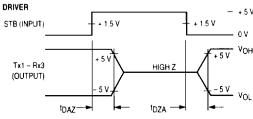

These are the EIA-232-E transmit signal output pins, which swing toward VDD and VSS. A logic 1 at a DI input causes the corresponding Tx output to swing toward VSS. The actual levels and slew rate achieved will depend on the output loading (RL/CL).

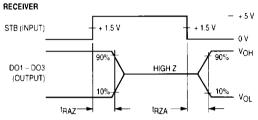

The minimum output impedance is 300  $\Omega$  when turned off.

#### SWITCHING CHARACTERISTICS

Vol

#### **ESD PROTECTION**

ESD protection on IC devices that have their pins accessible to the outside world is essential. High static voltages applied to the pins when someone touches them either directly or indirectly can cause damage to gate oxides and transistor junctions by coupling a portion of the energy from the I/O pin to the power supply buses of the IC. This coupling will usually

occur through the internal ESD protection diodes which are designed to do just that. The key to protecting the IC is to shunt as much of the energy to ground as possible before it enters the IC. The figure below shows a technique which will clamp the ESD voltage at approximately  $\pm$  15 V using the MMBZ15VDLT1. Any residual voltage which appears on the supply pins is shunted to ground through the capacitors C1 and C2.
