## **TDA8001** Smart card interface

Product specification  
Supersedes data of 1995 Feb 01  
File under Integrated Circuits, IC02

1996 Dec 12

## Smart card interface

## TDA8001

### FEATURES

- Protected I/O line
- $V_{CC}$  regulation (5 V  $\pm$ 5%, 100 mA max. with controlled rise and fall times)
- $V_{PP}$  generation (12.5, 15 or 21 V  $\pm$ 2.5%, 50 mA max., with controlled rise and fall times) (only at TDA8001 and TDA8001T)
- Clock generation (up to 10 MHz), with synchronous frequency doubling
- Overload, thermal and card extraction protections
- Current limitation in case of short-circuit
- Idle mode and special circuitry for spikes killing during powering on and off
- Two voltage supervisors (digital and analog supplies)
- Automatic activation and deactivation sequences through an independent internal clock
- Enhanced ESD protections on card side (4 kV min.)
- Easy chaining for multiple card readers
- ISO 7816 compatibility.

### APPLICATIONS

- Pay TV (multistandards conditional access system, videoguard, newsript)
- Multi-application smart card readers (banking, vending machine, electronic payment identification).

### GENERAL DESCRIPTION

The TDA8001 is a complete, low-cost analog interface which can be positioned between an asynchronous smart card (ISO 7816) and a microcontroller. It is directly compatible with the new Datacom chip verifier.

The complete supply, protection and control functions are realized with only a few external components, making this product very attractive for consumer applications (see Chapter "Application information").

### ORDERING INFORMATION

TYPE NUMBER	PACKAGE		
	NAME	DESCRIPTION	VERSION
TDA8001; TDA8001A	DIP28	plastic dual in-line package; 28 leads (600 mil)	SOT117-1
TDA8001T; TDA8001AT	SO28	plastic small outline package; 28 leads; body width 7.5 mm	SOT136-1

## PINNING

SYMBOL	PIN		DESCRIPTION
	TDA8001 TDA8001T	TDA8001A TDA8001AT	
XTAL	1	1	crystal connection
$\overline{\text{DETECT}}$	2	2	card extraction open collector output (active LOW)
I/O	3	3	data line to/from the card
RST	4	4	card reset output
CLK	5	5	clock output to the card
$\overline{\text{VPP12.5}}$	6	–	control input for applying the 12.5 V programming voltage (active LOW)
n.c.	–	6	not connected
$\overline{\text{VPP15}}$	7	–	control input for applying the 15 V programming voltage (active LOW)
n.c.	–	7	not connected
$\overline{\text{PRES}}$	8	8	card presence contact input (active LOW)
PRES	9	9	card presence contact input (active HIGH)
V <sub>PP</sub>	10	–	card programming voltage output
n.c.	–	10	not connected
V <sub>H</sub>	11	11	HIGH voltage supply for V <sub>PP</sub> generation
GND1	12	12	ground 1
V <sub>DD</sub>	13	13	positive supply voltage
V <sub>CC</sub>	14	14	card supply output voltage
V <sub>SUP</sub>	15	15	voltage supervisor input
DELAY	16	16	external capacitor connection for delayed reset timing
ALARM	17	17	open-collector reset output for the microcontroller (active HIGH)
$\overline{\text{ALARM}}$	18	18	open-collector reset output for the microcontroller (active LOW)
$\overline{\text{OFF}}$	19	19	open-collector interrupt output to the microcontroller (active LOW)
$\overline{\text{CMDVCC}}$	20	20	control input for applying supply voltage to the card (active LOW)
$\overline{\text{VPP21}}$	21	–	control input for applying the 21 V programming voltage (active LOW)
n.c.	–	21	not connected
CVNC	22	22	internally generated 5 V reference, present when V <sub>DD</sub> is on; to be decoupled externally (100 nF)
CMD3.5 or CDMTC	23	23	control input for having the crystal frequency divided-by-4 at pin CLK
CLKOUT2	24	24	clock output to the microcontroller, or any other R4590 (crystal frequency divided by two)
GND2	25	25	ground 2
RSTIN	26	26	card reset input from the microcontroller (active HIGH)
$\overline{\text{CMD7}}$ or CDMS	27	27	control input for having the crystal frequency divided by 2 at pin CLK
I/O(μC)	28	28	data line to/from the microcontroller

## Smart card interface

## TDA8001

### FUNCTIONAL DESCRIPTION

#### Power supply

The circuit operates within a supply voltage range of 6.7 to 18 V.  $V_{DD}$  and GND are the supply pins. All card contacts remain inactive during power up or down.

#### POWER UP

The logic part is powered first and is in the reset condition until  $V_{DD}$  reaches  $V_{th1}$ . The sequencer is blocked until  $V_{DD}$  reaches  $V_{th4} + V_{hys4}$ .

#### POWER DOWN

When  $V_{DD}$  falls below  $V_{th4}$ , an automatic deactivation of the contacts is performed.

#### Voltage supervisor

This block surveys the 5 V supply of the microcontroller ( $V_{SUP}$ ) in order to deliver a defined reset pulse and to avoid any transients on card contacts during power up or down of  $V_{SUP}$ . The voltage supervisor remains active even if  $V_{DD}$  is powered-down.

#### POWER ON

As long as  $V_{SUP}$  is below  $V_{th2} + V_{hys2}$  the capacitor  $C_{DEL}$ , connected to pin DELAY, will be discharged. When  $V_{SUP}$  rises to the threshold level,  $C_{DEL}$  will be recharged. ALARM and  $\overline{ALARM}$  remain active, and the sequencer is blocked until the voltage on the DELAY line reaches  $V_{th3}$ .

#### POWER DOWN (see Fig.4)

If  $V_{SUP}$  falls below  $V_{th2}$ ,  $C_{DEL}$  will be discharged, ALARM and  $\overline{ALARM}$  become active, and an automatic deactivation of the contacts is performed.

#### Clock circuitry (see Fig.5)

The clock signal (CLK) can be applied to the card in two different methods:

1. Generation by a crystal oscillator: the crystal, or the ceramic resonator (4 to 16 MHz) is connected to the XTAL pin.
2. Use of a signal frequency (up to 20 MHz), already present in the system and connected to the XTAL pin via a 10 nF capacitor (see Fig.14). In both cases the frequency is first divided-by-two.

If  $\overline{CMD7}$  (respectively  $\overline{CMD3.5}$ ) is LOW, the clock signal (its frequency again divided by two) is enabled and buffered before being fed to the CLK pin.

$\overline{CMD3.5}$  and internal ENRST are sampled in order to give the first clock pulse the correct width, and to avoid false pulses during frequency change.

The CLKOUT2 pins may be used to clock a microcontroller or an other TDA8001. The signal  $\frac{1}{2} f_{xtal}$  is available when the circuit is powered up.

#### State diagram

Once activated, the circuit has six possible modes of operation:

- Idle
- Activation
- Read
- Write
- Deactivation
- Fault.

Figure 6 shows the way these modes are accessible.

#### IDLE MODE

After reset, the circuit enters the IDLE state. A minimum number of circuits are active while waiting for the microcontroller to start a session.

- All card contacts are inactive
- I/O( $\mu$ C) is high impedance
- Voltage generators are stopped
- Oscillator or XTAL input is running, delivering CLKOUT2
- Voltage supervisors are active.

The  $\overline{DETECT}$  line is HIGH if a card is present (PRES and  $\overline{PRES}$  active) and LOW if a card is not present. The OFF line is HIGH if no hardware problem is detected.

#### ACTIVATION SEQUENCE

From the IDLE mode, the circuit enters the ACTIVATION mode when the microcontroller sets the  $\overline{CMDVCC}$  line (active LOW). The I/O( $\mu$ C) signal must not be LOW. The internal circuitry is activated, the internal clock starts and the sequence according to ISO7816 is performed:

- $V_{CC}$  rises from 0 to 5 V
- $V_{PP}$  rises from 0 to 5 V and I/O is enabled
- CLK and RST are enabled.

The time interval between steps 1 and 2 is 16  $\mu$ s, and 64  $\mu$ s between steps 2 and 3 (see Fig.7).

Smart card interface

TDA8001

READ MODE

When the activation sequence is completed and, after the card has replied its Answer-to-Reset, the TDA8001 will be in the READ mode. Data is exchanged between the card and the microcontroller via the I/O line.

WRITE MODE

Cards with EPROM memory need a programming voltage ( $V_{PP}$ ). When it is required to write to the internal memory of the card, the microcontroller sets one of the  $\overline{VPP12.5}$ ,  $\overline{VPP15}$  and  $\overline{VPP21}$  lines LOW, according to the programming value given in the Answer-to-Reset.  $V_{PP}$  rises from 5 V to the selected value with a typical slew rate of  $0.38 \text{ V}/\mu\text{s}$ . In order to respect the ISO 7816 slopes, the circuit generates  $V_{PP}$  by charging and discharging an internal capacitor. The voltage on this capacitor is then amplified by a power stage gain of 5, powered via an external supply pin  $V_H$  (30 V max).

DEACTIVATION SEQUENCE (see Fig.8)

When the session is completed, the microcontroller sets the  $\overline{CMDVCC}$  line to its HIGH state. The circuit then executes an automatic deactivation sequence by counting the sequencer back:

- RST falls to LOW and CLK is stopped
- I/O( $\mu\text{C}$ ) becomes high impedance and  $V_{PP}$  falls to 0 V
- $V_{CC}$  falls to 0 V.

The circuit returns to the IDLE mode on the next rising edge of the clock.

PROTECTIONS

Main fault conditions are monitored by the circuit:

- Short-circuit or overcurrent on  $V_{CC}$
- Short-circuit or overcurrent on  $V_{PP}$
- Card extraction during transaction
- Overheating problem
- $V_{SUP}$  drop-out
- $V_{DD}$  drop-out.

When one of these fault conditions is detected, the circuit pulls the interrupt line  $\overline{OFF}$  to its active LOW state and returns to the FAULT mode. The current on I/O is internally limited to 5 mA.

FAULT MODE (see Fig.9)

When a fault condition is written to the microcontroller via the  $\overline{OFF}$  line, the circuit initiates a deactivation sequence. After the deactivation sequence has been completed, the  $\overline{OFF}$  line is reset to its HIGH state after the microcontroller has reset the  $\overline{CMDVCC}$  line HIGH.

Fig.4 Alarm and delay as a function of  $V_{SUP}$  ( $C_{DEL}$  fixes the pulse width).

**LIMITING VALUES**

In accordance with the Absolute Maximum Rating System (IEC 134).

SYMBOL	PARAMETER	CONDITIONS	MIN.	MAX.	UNIT
V <sub>DD</sub>	supply voltage		-0.3	18	V
V <sub>x1</sub>	voltage on pins $\overline{VPP21}$ , $\overline{VPP15}$ , $\overline{VPP12.5}$ , $\overline{PRES}$ , $\overline{PRES}$ , $\overline{CMDVCC}$ , $\overline{OFF}$ , $\overline{ALARM}$ , $\overline{DETECT}$ and $\overline{RSTIN}$		0	V <sub>DD</sub>	V
V <sub>H</sub>	voltage on pin V <sub>H</sub>		0	30	V
V <sub>PP</sub>	voltage on pin V <sub>PP</sub>		0	V <sub>H</sub>	V
V <sub>SUP</sub>	voltage on pin V <sub>SUP</sub>		0	12	V
V <sub>x2</sub>	voltage on pins $\overline{ALARM}$ and $\overline{DELAY}$		0	V <sub>SUP</sub>	V
V <sub>x3</sub>	voltage on pins XTAL, I/O( $\mu$ C), $\overline{CLKOUT2}$ , $\overline{CMD7}$ , $\overline{CMD3.5}$ and $\overline{CVNC}$		0	6.0	V
V <sub>x4</sub>	voltage on pins I/O, $\overline{RST}$ , $\overline{CLK}$ and V <sub>CC</sub>	duration < 1 ms	0	7.0	V
P <sub>tot</sub>	continuous total power dissipation	TDA8001; T <sub>amb</sub> = +70 °C; note 1; see Fig.10	-	2	W
		TDA8001T; T <sub>amb</sub> = +70 °C; note 1; see Fig.11	-	0.92	W
T <sub>stg</sub>	storage temperature		-55	+150	°C
V <sub>es</sub>	electrostatic voltage on pins I/O, V <sub>CC</sub> , V <sub>PP</sub> , $\overline{RST}$ , $\overline{CLK}$ , $\overline{PRES}$ and $\overline{PRES}$		-6	+6	kV
	electrostatic voltage on other pins		-2	+2	kV

**Note**

1.  $P_{tot} = V_{DD} \times (I_{DD(unloaded)} + \sum I_{signals}) + I_{CC} \times (V_{DD} - V_{CC}) + \max.\{(V_H - V_{PP}) \times I_{PP(read)} + (V_H - V_{PP}) \times I_{PP(write)}\} + V_H \times I_{H(unloaded)} + V_{SUP} \times I_{SUP} + (V_{DD} - CVNC) \times I_{CVNC}$ , where 'signals' means all signal pins, except supply pins.

Smart card interface

TDA8001

**HANDLING**

Every pin withstands the ESD test according to MIL-STD-883C class 3 for card contacts, class 2 for the remaining. Method 3015 (HBM 1500 Ω, 100 pF) 3 pulses positive and 3 pulse negative on each pin referenced to ground.

**THERMAL CHARACTERISTICS**

SYMBOL	PARAMETER	VALUE	UNIT

t <sub>3</sub>	start of the window for sending CLK to the card		–	–	70	μs
t <sub>5</sub>	end of the window for sending CLK to the card		80	–	–	μs
t <sub>st</sub>	maximum pulse width on CMDV <sub>CC</sub> before V <sub>CC</sub> starts rising		–	–	30	μs

Notes

1. Pins  $\overline{\text{CMDVCC}}$ ,  $\overline{\text{VPP21}}$ ,  $\overline{\text{VPP15}}$ ,  $\overline{\text{VPP12.5}}$ ,  $\overline{\text{CMD7}}$ ,  $\overline{\text{CMD3.5}}$  and  $\overline{\text{PRES}}$  are active LOW; pins RSTIN and PRES are active HIGH.
2. The transition time and duty cycle definitions are shown in Fig.12;  $\delta = \frac{t_1}{t_1 + t_2}$ .
3. P is the card programming voltage set by pin  $\overline{\text{VPP12.5}}$ ,  $\overline{\text{VPP15}}$  or  $\overline{\text{VPP21}}$ .
4. The tests for dynamic response of both V<sub>PP</sub> and V<sub>CC</sub> are performed at 1 Hz, 10 kHz, 100 kHz and 1 MHz, with a capacitive load of 100 nF.
5. This condition ensures proper starting of the oscillator with crystals having a series resistance up to 100 Ω.

## TDA8001

### SOLDERING

#### Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our "IC Package Databook" (order code 9398 652 90011).

#### DIP

##### SOLDERING BY DIPPING OR BY WAVE

The maximum permissible temperature of the solder is 260 °C; solder at this temperature must not be in contact with the joint for more than 5 seconds. The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified maximum storage temperature ( $T_{stg\ max}$ ). If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

##### REPAIRING SOLDERED JOINTS

Apply a low voltage soldering iron (less than 24 V) to the lead(s) of the package, below the seating plane or not more than 2 mm above it. If the temperature of the soldering iron bit is less than 300 °C it may remain in contact for up to 10 seconds. If the bit temperature is between 300 and 400 °C, contact may be up to 5 seconds.

#### SO

##### REFLOW SOLDERING

Reflow soldering techniques are suitable for all SO packages.

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary between 50 and 300 seconds depending on heating method. Typical reflow temperatures range from 215 to 250 °C.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 minutes at 45 °C.

##### WAVE SOLDERING

Wave soldering techniques can be used for all SO packages if the following conditions are observed:

- A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.
- The longitudinal axis of the package footprint must be parallel to the solder flow.
- The package footprint must incorporate solder thieves at the downstream end.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than 150 °C within 6 seconds. Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

##### REPAIRING SOLDERED JOINTS

Fix the component by first soldering two diagonally-opposite end leads. Use only a low voltage soldering iron (less than 24 V) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.

**DEFINITIONS**

<b>Data sheet status</b>	
Objective specification	This data sheet contains target or goal specifications for product development.
Preliminary specification	This data sheet contains preliminary data; supplementary data may be published later.
Product specification	This data sheet contains final product specifications.
<b>Limiting values</b>	
Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.	
<b>Application information</b>	
Where application information is given, it is advisory and does not form part of the specification.	

**LIFE SUPPORT APPLICATIONS**

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.
