## 3-Channel DC-DC Converter

## élantec.

The EL7583 is a 3-channel DC-DC converter IC which is designed primarily for use in TFT/LCD applications. It features a PWM boost converter with 2.7 V to 14 V input capability and 5 V to 17 V output, which powers the column drivers and provides up to 470 mA @ 12V, 370mA @ 15 V from 5 V supply. A pair of charge pump control circuits provide regulated outputs of $\mathrm{V}_{\mathrm{ON}}$ and $\mathrm{V}_{\text {OFF }}$ supplies at 8 V to 40 V and -5 V to -40 V , respectively, each at up to 60 mA .

The EL7583 features adjustable switching frequency, adjustable soft start, and a separate output $V_{\text {ON }}$ enable control to allow selection of supply start-up sequence. An over-temperature feature is provided to allow the IC to be automatically protected from excessive power dissipation.

The EL7583 is available in a 20-pin TSSOP package and is specified for operation over the full $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ temperature range.

## Ordering Information

| PART <br> NUMBER | PACKAGE |  <br> REEL | PKG. DWG. \# |
| :--- | :---: | :---: | :---: |
| EL7583IR | 20-Pin TSSOP | - | MDP0044 |
| EL7583IR-T7 | 20-Pin TSSOP | $7 "$ | MDP0044 |

## Features

- TFT/LCD display supply
- Boost regulator
- $V_{\text {ON }}$ charge pump
- V VFF charge pump
- 2.7 V to $14 \mathrm{~V} \mathrm{~V}_{\mathrm{IN}}$ supply
- $5 \mathrm{~V}<\mathrm{V}_{\mathrm{BOOST}}<17 \mathrm{~V}$
- $5 \mathrm{~V}<\mathrm{V}_{\mathrm{ON}}<40 \mathrm{~V}$
- $-40 \mathrm{~V}<\mathrm{V}_{\text {OFF }}<0 \mathrm{~V}$
- $\mathrm{V}_{\mathrm{BOOST}}=12 \mathrm{~V} @ 470 \mathrm{~mA}$
- $\mathrm{V}_{\text {BOOSt }}=15 \mathrm{~V} @ 370 \mathrm{~mA}$
- High frequency, small inductor DC-DC boost circuit
- Over 90\% efficient DC-DC boost converter capability
- Adjustable frequency
- Adjustable soft-start
- Adjustable outputs
- Small parts count

## Applications

- TFT-LCD panels
- PDAs

## Functional Block Diagram

## Applications Information

The EL7583 is high efficiency multiple output power solution designed specifically for thin-film transistor (TFT) liquid crystal display (LCD) applications. The device contains one high current boost converter and two low power charge pumps ( $\mathrm{V}_{\mathrm{ON}}$ and $\mathrm{V}_{\mathrm{OFF}}$ ).

The boost converter contains an integrated N -channel MOSFET to minimize the number of external components. The converter output voltage can be set from 5 V to 18 V with external resistors. The $\mathrm{V}_{\text {ON }}$ and $\mathrm{V}_{\text {OFF }}$ charge pumps are independently regulated to positive and negative voltages using external resistors. Output voltages as high as 40 V can be achieved with additional capacitors and diodes.

## Boost Converter

The boost converter operates in constant frequency pulse-width-modulation (PWM) mode. Quiescent current for the EL7583 is only 5 mA when enabled, and since only the low side MOSFET is used, switch drive current is minimized. $90 \%$ efficiency is achieved in most common application operating conditions.

A functional block diagram with typical circuit configuration is shown on previous page. Regulation is performed by the PWM comparator which regulates the output voltage by comparing a divided output voltage with an internal reference voltage. The PWM comparator outputs its result to the PWM logic. The PWM logic switches the MOSFET on and off through the gate drive circuit. Its switching frequency is external adjustable with a resistor from timing control pin ( $\mathrm{R}_{\text {OSC }}$ ) to ground. The boost converter has 200 kHz to 1.2 MHz operating frequency range.

## Start-Up

After $V_{\text {DDB }}$ reaches a threshold of about 2V, the power MOSFET is controlled by the start-up oscillator, which generates fixed duty-ratio of 0.5-0.7 at a frequency of several hundred kilohertz. This will boost the output voltage, providing the initial output current load is not too great (<250mA).

When $\mathrm{V}_{\text {DDB }}$ reaches about 3.7 V , the PWM comparator takes over the control. The duty ratio will be decided by the multiple-input direct summing comparator, Max_Duty signal (about 90\% duty-ratio), and the Current Limit Comparator, whichever is the smallest.

The soft-start is provided by the current limit comparator. As the internal $12 \mu \mathrm{~A}$ current source charges the external softstart capacitor, the peak MOSFET current is limited by the voltage on the capacitor. This in turn controls the rising rate of output voltage.

The regulator goes through the start-up sequence as well after the ENBN signal is pulled to HI .

## Steady-State Operation

When the output reaches the preset voltage, the regulator operates at steady state. Depending on the input/output condition and component, the inductor operates at either continuous-conduction mode or discontinuous-conduction mode.

In the continuous-conduction mode, the inductor current is a triangular waveform and LX voltage a pulse waveform. In the discontinuous-conduction mode, the inductor current is completely 'dried-out' before the MOSFET is turned on again. The input voltage source, the inductor, and the MOSFET and output diode parasitic capacitors forms a resonant circuit. Oscillation will occur in this period. This oscillation is normal and will not affect the regulation.

At very low load, the MOSFET will skip pulse sometimes. This is normal.

## Current Limit

The MOSFET current limit is nominal $\mathrm{I}_{\text {LMT }}=1.75$. This restricts the maximum output current IOMAX based on the following formula:
$\mathrm{I}_{\mathrm{OMAX}}=\left(\mathrm{I}_{\mathrm{LMT}}-\frac{\Delta \mathrm{L}}{2}\right) \times \frac{\mathrm{V}_{\mathrm{IN}}}{\mathrm{V}_{\mathrm{O}}}$
where:

- $\Delta \mathrm{I}_{\mathrm{L}}$ is the inductor peak-to-peak current ripple and is decided by:
$\Delta \mathrm{I}_{\mathrm{L}}=\frac{\mathrm{V}_{\mathrm{IN}}}{\mathrm{L}} \times \frac{\mathrm{D}}{\mathrm{F}_{\mathrm{S}}}$
- D is the MOSFET turn-on radio and is decided by:
$D=\frac{V_{O}-V_{I N}}{V_{O}}$
- $F_{S}$ is the switching frequency.

The following table gives typical values:
(Margins are considered 10\%, 3\%, 20\%, 10\%, and 15\% on $\mathrm{V}_{\mathrm{IN}}, \mathrm{V}_{\mathrm{O}}, \mathrm{L}, \mathrm{F}_{\mathrm{S}}$, and $\mathrm{I}_{\mathrm{LMT}}$, respectively)

TABLE 1. MAXIMUM CONTINUOUS OUTPUT CURRENT

| 12 | 18 | 10 | 1000 | 830 |

## Component Considerations

## Input Capacitor

It is recommended that $\mathrm{C}_{\mathrm{IN}}$ is larger than $10 \mu \mathrm{~F}$.
Theoretically, the input capacitor has ripple current of $\Delta I_{\mathrm{L}}$. Due to high-frequency noise in the circuit, the input current ripple may exceed the theoretical value. Larger capacitor will reduce the ripple further.

## Boost Inductor

The inductor has peak and average current decided by:
$I_{L P K}=I_{L A V G}+\frac{\Delta I_{L}}{2}$
$\mathrm{I}_{\text {LAVG }}=\frac{\mathrm{I}_{\mathrm{O}}}{1-\mathrm{D}}$
The inductor should be chosen to be able to handle this current. Furthermore, due to the fixed internal compensation, it is recommended that maximum inductance of $10 \mu \mathrm{H}$ and $15 \mu \mathrm{H}$ to be used in the 5 V and 12 V or higher output voltage, respectively.

The output diode has average current of $\mathrm{I}_{\mathrm{O}}$, and peak current the same as the inductor's peak current. Schottky diode is recommended and it should be able to handle those currents.

## Feedback Resistor Network

An external resistor divider is required to divide the output voltage down to the nominal reference voltage. Current drawn by the resistor network should be limited to maintain the overall converter efficiency. The maximum value of the resistor network is limited by the feedback input bias current and the potential for noise being coupled into the feedback pin. A resistor network in the order of $200 \mathrm{k} \Omega$ is recommended. The boost converter output voltage is determined by the following relationship:
$V_{\text {BOOST }}=\frac{R_{1}+R_{2}}{R_{1}} \times V_{\text {FBB }}$
where $\mathrm{V}_{\mathrm{FBB}}$ is 1.300 V .

A 1 nF compensation capacitor across the feedback resistor to ground is recommended to keep the converter in stable operation at low output current and high frequency conditions.

## Schottky Diode

Speed, forward voltage drop, and reverse current are the three most critical specifications for selecting the Schottky diode. The entire output current flows through the diode, so the diode average current is the same as the average load current and the peak current is the same as the inductor peak current. When selecting the diode, one must consider the forward voltage drop at the peak diode current. On the Elantec demo board, MBRM120 is selected. Its forward voltage drop is 450 mV at 1 A forward current.

## Output Capacitor

The EL7583 is specially compensated to be stable with capacitors which have a worst-case minimum value of $10 \mu \mathrm{~F}$ at the particular $\mathrm{V}_{\text {OUT }}$ being set. Output ripple voltage requirements also determine the minimum value and the type of capacitors. Output ripple voltage consists of two components - the voltage drop caused by the switching current though the ESR of the output capacitor and the charging and discharging of the output capacitor:
$V_{\text {RIPPLE }}=I_{\text {LPK }} \times E S R+\frac{V_{\text {OUT }}-V_{\text {IN }}}{V_{\text {OUT }}} \times \frac{I_{\text {OUT }}}{C_{\text {OUT }} \times F S}$

For low ESR ceramic capacitors, the output ripple is dominated by the charging/discharging of the output capacitor.

In addition to the voltage rating, the output capacitor should also be able to handle the RMS current is given by:
$I_{\text {CORMS }}=\sqrt{(1-D) \times\left(D+\frac{\Delta I_{L}{ }^{2}}{I_{L A V G}{ }^{2}} \times \frac{1}{12}\right)} \times I_{\text {LAVG }}$

## Positive and Negative Charge Pump (VON and $V_{\text {OFF }}$ )

The EL7583 contains two independent charge pumps (see charge pump block and connection diagram.) The negative charge pump inverts the $V_{\text {DDN }}$ supply voltage and provides a regulated negative output voltage. The positive charge pump doubles the $V_{\text {DDP }}$ supply voltage and provides a regulated positive output voltage. The regulation of both the negative and positive charge pumps is generated by the internal comparator that senses the output voltage and compares it with and internal reference. The switching frequency of the charge pump is set to $1 / 2$ the boost converter switching frequency.
The pumps use pulse width modulation to adjust the pump period, depending on the load present. The pumps are shortcircuit protected to 180 mA at 12 V supply and can provide 15 mA to 60 mA for 6 V to 12 V supply.

## Single Stage Charge Pump

## Positive Charge Pump Design Considerations

A single stage charge pump is shown above. The maximum
$\mathrm{V}_{\mathrm{ON}}$ output voltage is determined by the following equation:
$\mathrm{V}_{\mathrm{ON}}(\max ) \leq 2 \times \mathrm{V}_{\text {DDCPP }}-\mathrm{I}_{\mathrm{OUT}} \times 2 \times\left(\mathrm{R}_{\mathrm{ONN}}+\mathrm{R}_{\mathrm{ONP}}\right)-2 \times \mathrm{V}_{\text {DIODE }}-\mathrm{I}_{\mathrm{OUT}} \times \frac{1}{0.5 \times \mathrm{F}_{\mathrm{S}} \times \mathrm{C}_{\mathrm{CPP}}}-\mathrm{I}_{\mathrm{OUT}} \times \frac{1}{0.5 \times \mathrm{F}_{\mathrm{S}} \times \mathrm{C}_{\mathrm{OUT} 1}}$
where:

- $\mathrm{R}_{\mathrm{ONN}}$ and $\mathrm{R}_{\mathrm{ONP}}$ resistance values depend on the $\mathrm{V}_{\mathrm{DDP}}$ voltage levels. For 12 V supply, $\mathrm{R}_{\mathrm{ON}}$ is typically $33 \Omega$. For 6 V supply, $\mathrm{R}_{\mathrm{ON}}$ is typically $45 \Omega$.
If additional stage is required, the LX switching signal is recommended to drive the additional charge pump diodes. The drive impedance at the LX switching is typically $150 \mathrm{~m} \Omega$. The figure below illustrates an implementation for two-stage positive charge pump circuit.

## Two-Stage Positive Charge Pump Circuit

The maximum $\mathrm{V}_{\mathrm{ON}}$ output voltage for $\mathrm{N}+1$ stage charge pump is:
$\mathrm{V}_{\mathrm{ON}}(\max ) \leq 2 \times \mathrm{V}_{\text {DDP }}-\mathrm{I}_{\mathrm{OUT}} \times 2 \times\left(\mathrm{R}_{\mathrm{ONN}}+\mathrm{R}_{\mathrm{ONP}}\right)-2 \times \mathrm{V}_{\text {DIODE }}-\mathrm{I}_{\mathrm{OUT}} \times \frac{1}{0.5 \times \mathrm{F}_{\mathrm{S}} \times \mathrm{C}_{\mathrm{CPP}}}-\mathrm{I}_{\mathrm{OUT}} \times$
$\frac{1}{0.5 \times \mathrm{F}_{\mathrm{S}} \times \mathrm{C}_{\text {OUT } 1}}+\mathrm{N} \times \mathrm{V}_{\text {LX }}(\max )-\mathrm{N} \times\left(2 \times \mathrm{V}_{\text {DIODE }}+\mathrm{I}_{\mathrm{OUT}} \times \frac{1}{0.5 \times \mathrm{F}_{\mathrm{S}} \times \mathrm{C}_{\mathrm{CPP}}}+\mathrm{I}_{\mathrm{OUT}} \times \frac{1}{0.5 \times \mathrm{F}_{\mathrm{S}} \times \mathrm{C}_{\text {OUT } 1}}\right)$
$\mathrm{R}_{11}$ and $\mathrm{R}_{12}$ set the $\mathrm{V}_{\mathrm{ON}}$ output voltage:
$\mathrm{V}_{\mathrm{ON}}=\mathrm{V}_{\mathrm{FBP}} \times \frac{\mathrm{R}_{11}+\mathrm{R}_{12}}{\mathrm{R}_{11}}$
where $V_{F B P}$ is 1.310 V .

## Negative Charge Pump Design Considerations

The criteria for the negative charge pump is similar to the positive charge pump. For a single stage charge pump, the maximum $\mathrm{V}_{\text {OFF }}$ output voltage is:
$\mathrm{V}_{\mathrm{OFF}}(\max ) \geq \mathrm{I}_{\mathrm{OUT}} \times 2 \times\left(\mathrm{R}_{\mathrm{ONN}}+\mathrm{R}_{\mathrm{ONP}}\right)+2 \times \mathrm{V}_{\text {DIODE }}-\mathrm{I}_{\mathrm{OUT}} \times \frac{1}{0.5 \times \mathrm{F}_{\mathrm{S}} \times \mathrm{C}_{\mathrm{CPN}}}-\mathrm{I}_{\mathrm{OUT}} \times \frac{1}{0.5 \times \mathrm{F}_{\mathrm{S}} \times \mathrm{C}_{\mathrm{OUT}} 2}-\mathrm{V}_{\mathrm{DDN}}$
Similar to positive charge pump, if additional stage is required, the LX switching signal is recommended to drive the additional charge pump diodes. The figure on the next page shows a two stage negative charge pump circuit.

## Two-Stage Negative Charge Pump Circuit

The maximum $\mathrm{V}_{\text {OFF }}$ output voltage for $\mathrm{N}+1$ stage charge pump is:
$\mathrm{V}_{\mathrm{OFF}}(\max ) \geq \mathrm{I}_{\mathrm{OUT}} \times 2 \times\left(\mathrm{R}_{\mathrm{ONN}}+\mathrm{R}_{\mathrm{ONP}}\right)+2 \times \mathrm{V}_{\text {DIODE }}-\mathrm{I}_{\mathrm{OUT}} \times \frac{1}{0.5 \times \mathrm{F}_{\mathrm{S}} \times \mathrm{C}_{\mathrm{CPN}}}-\mathrm{I}_{\mathrm{OUT}} \times \frac{1}{0.5 \times \mathrm{F}_{\mathrm{S}} \times \mathrm{C}_{\text {OUT2 }}}$.
$\mathrm{V}_{\text {DDN }}-\mathrm{N} \times \mathrm{V}_{\mathrm{LX}}(\max )+\mathrm{N} \times\left(2 \times \mathrm{V}_{\text {DIODE }}+\mathrm{I}_{\mathrm{OUT}} \times \frac{1}{0.5 \times \mathrm{F}_{\mathrm{S}} \times \mathrm{C}_{\mathrm{CPN}}}+\mathrm{I}_{\mathrm{OUT}} \times \frac{1}{0.5 \times \mathrm{F}_{\mathrm{S}} \times \mathrm{C}_{\text {OUT2 }}}\right)$
$\mathrm{R}_{21}$ and $\mathrm{R}_{22}$ determine $\mathrm{V}_{\text {OFF }}$ output voltage:
$V_{\text {OFF }}=-V_{\text {REF }} \times \frac{R_{21}}{R_{22}}$
where $\mathrm{V}_{\text {REF }}$ is 1.310 V .

## Over-Temperature Protection

An internal temperature sensor continuously monitors the die temperature. In the event that die temperature exceeds the thermal trip point, the device will shut down and disable itself. The upper and lower trip points are typically set to $130^{\circ} \mathrm{C}$ and $90^{\circ} \mathrm{C}$ respectively.

## PCB Layout Guidelines

Careful layout is critical in the successful operation of the application. The following layout guidelines are recommended to achieve optimum performance.

- $V_{\text {REF }}$ and $V_{\text {DDB }}$ bypass capacitors should be placed next to the pins.
- Place the boost converter diode and inductor close to the LX pins.
- Place the boost converter output capacitor close to the PGND pins.
- Locate feedback dividers close to their respected feedback pins to avoid switching noise coupling into the high impedance node.
- Place the charge pump feedback resistor network after the diode and output capacitor node to avoid switching noise.
- All low-side feedback resistors should be connected directly to $\mathrm{V}_{\text {SSB }}$. $\mathrm{V}_{\text {SSB }}$ should be connected to the power ground close at one point only.
A demo board is available to illustrate the proper layout implementation.

## Typical Application Circuit

## TSSOP Package Outline Drawing

NOTE: The package drawing shown here may not be the latest version. To check the latest revision, please reter to the Intersil website at [http://www.intersil.com/design/packages/index.asp](http://www.intersil.com/design/packages/index.asp)

All Intersil U.S. products are manufactured, assembled and tested utilizing ISO9000 quality systems. Intersil Corporation's quality certifications can be viewed at www.intersil.com/design/quality
