

## M29W017D

16 Mbit (2Mb x8, Uniform Block)  
3V Supply Flash Memory

PRELIMINARY DATA

### FEATURES SUMMARY

- SUPPLY VOLTAGE
  - $V_{CC} = 2.7V$  to  $3.6V$  for Program, Erase and Read
- ACCESS TIME: 70, 90ns
- PROGRAMMING TIME
  - $10\mu s$  per Byte typical
- 32 UNIFORM 64 KByte MEMORY BLOCKS
- PROGRAM/ERASE CONTROLLER
  - Embedded Byte Program algorithms
- ERASE SUSPEND and RESUME MODES
  - Read and Program another Block during Erase Suspend
- UNLOCK BYPASS PROGRAM COMMAND
  - Faster Production/Batch Programming
- TEMPORARY BLOCK UNPROTECTION MODE
- COMMON FLASH INTERFACE
  - 64 bit Security Code
- LOW POWER CONSUMPTION
  - Standby and Automatic Standby
- 100,000 PROGRAM/ERASE CYCLES per BLOCK
- ELECTRONIC SIGNATURE
  - Manufacturer Code: 20h
  - Device Code: C8h

## SUMMARY DESCRIPTION

The M29W017D is a 16 Mbit (2Mb x8) non-volatile memory that can be read, erased and re-programmed. These operations can be performed using a single low voltage (2.7 to 3.6V) supply. On power-up the memory defaults to its Read mode where it can be read in the same way as a ROM or EPROM.

The memory is divided into 32 blocks of 64KBytes (see Table 16, Block Addresses) that can be erased independently so it is possible to preserve valid data while old data is erased. Each block can be protected independently to prevent accidental Program or Erase commands from modifying the memory. Program and Erase commands are written to the Command Interface of the memory. An on-chip Program/Erase Controller simplifies the

process of programming or erasing the memory by taking care of all of the special operations that are required to update the memory contents. The end of a program or erase operation can be detected and any error conditions identified. The command set required to control the memory is consistent with JEDEC standards.

Chip Enable, Output Enable and Write Enable signals control the bus operation of the memory. They allow simple connection to most microprocessors, often without additional logic.

The memory is offered in TSOP40 (10 x 20mm) and TFBGA48 (0.8mm pitch) packages. The memory is supplied with all the bits erased (set to '1').

## SIGNAL DESCRIPTIONS

See Figure 2, Logic Diagram, and Table 1, Signal Names, for a brief overview of the signals connected to this device.

**Address Inputs (A0-A20).** The Address Inputs select the cells in the memory array to access during Bus Read operations. During Bus Write operations they control the commands sent to the Command Interface of the internal state machine.

**Data Inputs/Outputs (DQ0-DQ7).** The Data I/O outputs the data stored at the selected address during a Bus Read operation. During Bus Write operations they represent the commands sent to the Command Interface of the internal state machine.

**Chip Enable ( $\bar{E}$ ).** The Chip Enable,  $\bar{E}$ , activates the memory, allowing Bus Read and Bus Write operations to be performed. When Chip Enable is High,  $V_{IH}$ , all other pins are ignored.

**Output Enable ( $\bar{G}$ ).** The Output Enable,  $\bar{G}$ , controls the Bus Read operation of the memory.

**Write Enable ( $\bar{W}$ ).** The Write Enable,  $\bar{W}$ , controls the Bus Write operation of the memory's Command Interface.

**Reset/Block Temporary Unprotect (RP).** The Reset/Block Temporary Unprotect pin can be used to apply a Hardware Reset to the memory or to temporarily unprotect all Blocks that have been protected.

A Hardware Reset is achieved by holding Reset/Block Temporary Unprotect Low,  $V_{IL}$ , for at least  $t_{PLPX}$ . After Reset/Block Temporary Unprotect goes High,  $V_{IH}$ , the memory will be ready for Bus Read and Bus Write operations after  $t_{PHEL}$  or  $t_{RHEL}$ , whichever occurs last. See the Ready/Busy Output section, Table 13 and Figure 13, Reset/Temporary Unprotect AC Characteristics for more details.

Holding  $\bar{RP}$  at  $V_{ID}$  will temporarily unprotect the protected Blocks in the memory. Program and Erase operations on all blocks will be possible.

The transition from  $V_{IH}$  to  $V_{ID}$  must be slower than  $t_{PHPHH}$ .

**Ready/Busy Output ( $\bar{RB}$ ).** The Ready/Busy pin is an open-drain output that can be used to identify when the device is performing a Program or Erase operation. During Program or Erase operations Ready/Busy is Low,  $V_{OL}$ . Ready/Busy is high-impedance during Read mode, Auto Select mode and Erase Suspend mode.

After a Hardware Reset, Bus Read and Bus Write operations cannot begin until Ready/Busy becomes high-impedance. See Table 13 and Figure 13, Reset/Temporary Unprotect AC Characteristics.

The use of an open-drain output allows the Ready/Busy pins from several memories to be connected to a single pull-up resistor. A Low will then indicate that one, or more, of the memories is busy.

**V<sub>CC</sub> Supply Voltage (2.7V to 3.6V).**  $V_{CC}$  provides the power supply for all operations (Read, Program and Erase).

The Command Interface is disabled when the  $V_{CC}$  Supply Voltage is less than the Lockout Voltage,  $V_{LKO}$ . This prevents Bus Write operations from accidentally damaging the data during power up, power down and power surges. If the Program/Erase Controller is programming or erasing during this time then the operation aborts and the memory contents being altered will be invalid.

A 0.1 $\mu$ F capacitor should be connected between the  $V_{CC}$  Supply Voltage pin and the  $V_{SS}$  Ground pin to decouple the current surges from the power supply. See Figure 10, AC Measurement Load Circuit. The PCB track widths must be sufficient to carry the currents required during program and erase operations,  $I_{CC3}$ .

**V<sub>SS</sub> Ground.**  $V_{SS}$  is the reference for all voltage measurements.

## BUS OPERATIONS

There are five standard bus operations that control the device. These are Bus Read, Bus Write, Output Disable, Standby and Automatic Standby. See Tables 2, Bus Operations, for a summary. Typically glitches of less than 5ns on Chip Enable or Write Enable are ignored by the memory and do not affect bus operations.

**Bus Read.** Bus Read operations read from the memory cells, or specific registers in the Command Interface. A valid Bus Read operation involves setting the desired address on the Address Inputs, applying a Low signal,  $V_{IL}$ , to Chip Enable and Output Enable and keeping Write Enable High,  $V_{IH}$ . The Data Inputs/Outputs will output the value, see Figure 10, Read Mode AC Waveforms, and Table 10, Read AC Characteristics, for details of when the output becomes valid.

**Bus Write.** Bus Write operations write to the Command Interface. A valid Bus Write operation begins by setting the desired address on the Address Inputs. The Address Inputs are latched by the Command Interface on the falling edge of Chip Enable or Write Enable, whichever occurs last. The Data Inputs/Outputs are latched by the Command Interface on the rising edge of Chip Enable or Write Enable, whichever occurs first. Output Enable must remain High,  $V_{IH}$ , during the whole Bus Write operation. See Figures 11 and 12, Write AC Waveforms, and Tables 11 and 12, Write AC Characteristics, for details of the timing requirements.

**Output Disable.** The Data Inputs/Outputs are in the high impedance state when Output Enable is High,  $V_{IH}$ .

**Standby.** When Chip Enable is High,  $V_{IH}$ , the memory enters Standby mode and the Data Inputs/Outputs pins are placed in the high-imped-

ance state. To reduce the Supply Current to the Standby Supply Current,  $I_{CC2}$ , Chip Enable should be held within  $V_{CC} \pm 0.2V$ . For the Standby current level see Table 9, DC Characteristics.

During program or erase operations the memory will continue to use the Program/Erase Supply Current,  $I_{CC3}$ , for Program or Erase operations until the operation completes.

**Automatic Standby.** If CMOS levels ( $V_{CC} \pm 0.2V$ ) are used to drive the bus and the bus is inactive for 300ns or more the memory enters Automatic Standby where the internal Supply Current is reduced to the Standby Supply Current,  $I_{CC2}$ . The Data Inputs/Outputs will still output data if a Bus Read operation is in progress.

### Special Bus Operations

Additional bus operations can be performed to read the Electronic Signature and also to apply and remove Block Protection. These bus operations are intended for use by programming equipment and are not usually used in applications. They require  $V_{ID}$  to be applied to some pins.

**Electronic Signature.** The memory has two codes, the manufacturer code and the device code, that can be read to identify the memory. These codes can be read by applying the signals listed in Tables 2, Bus Operations.

**Block Protection and Blocks Unprotection.** Each block can be separately protected against accidental Program or Erase. Protected blocks can be unprotected to allow data to be changed.

There are two methods available for protecting and unprotecting the blocks, one for use on programming equipment and the other for in-system use. Block Protect and Chip Unprotect operations are described in Appendix C.

**Table 2. Bus Operations**

Operation	$\bar{E}$	$\bar{G}$	$\bar{W}$	Address Inputs A0-A20	Data Inputs/Outputs DQ7-DQ0
Bus Read	$V_{IL}$	$V_{IL}$	$V_{IH}$	Cell Address	Data Output
Bus Write	$V_{IL}$	$V_{IH}$	$V_{IL}$	Command Address	Data Input
Output Disable	X	$V_{IH}$	$V_{IH}$	X	Hi-Z
Standby	$V_{IH}$	X	X	X	Hi-Z
Read Manufacturer Code	$V_{IL}$	$V_{IL}$	$V_{IH}$	A0 = $V_{IL}$ , A1 = $V_{IL}$ , A9 = $V_{ID}$ , Others $V_{IL}$ or $V_{IH}$	20h
Read Device Code	$V_{IL}$	$V_{IL}$	$V_{IH}$	A0 = $V_{IH}$ , A1 = $V_{IL}$ , A9 = $V_{ID}$ , Others $V_{IL}$ or $V_{IH}$	C8h

Note: X =  $V_{IL}$  or  $V_{IH}$ .

## COMMAND INTERFACE

All Bus Write operations to the memory are interpreted by the Command Interface. Commands consist of one or more sequential Bus Write operations. Failure to observe a valid sequence of Bus Write operations will result in the memory returning to Read mode. The long command sequences are imposed to maximize data security.

Refer to Table 3, Commands, in conjunction with the following text descriptions.

**Read/Reset Command.** The Read/Reset command returns the memory to its Read mode where it behaves like a ROM or EPROM, unless otherwise stated. It also resets the errors in the Status Register. Either one or three Bus Write operations can be used to issue the Read/Reset command.

The Read/Reset Command can be issued, between Bus Write cycles before the start of a program or erase operation, to return the device to read mode. Once the program or erase operation has started the Read/Reset command is no longer accepted. The Read/Reset command will not abort an Erase operation when issued while in Erase Suspend.

**Auto Select Command.** The Auto Select command is used to read the Manufacturer Code, the Device Code and the Block Protection Status. Three consecutive Bus Write operations are required to issue the Auto Select command. Once the Auto Select command is issued the memory remains in Auto Select mode until a Read/Reset command is issued. Read CFI Query and Read/Reset commands are accepted in Auto Select mode, all other commands are ignored.

From the Auto Select mode the Manufacturer Code can be read using a Bus Read operation with  $A0 = V_{IL}$  and  $A1 = V_{IL}$ . The other address bits may be set to either  $V_{IL}$  or  $V_{IH}$ . The Manufacturer Code for STMicroelectronics is 20h.

The Device Code can be read using a Bus Read operation with  $A0 = V_{IH}$  and  $A1 = V_{IL}$ . The other address bits may be set to either  $V_{IL}$  or  $V_{IH}$ . The Device Code for the M29W017D is C8h.

The Block Protection Status of each block can be read using a Bus Read operation with  $A0 = V_{IL}$ ,  $A1 = V_{IH}$ , and A16-A20 specifying the address of the block. The other address bits may be set to either  $V_{IL}$  or  $V_{IH}$ . If the addressed block is protected then 01h is output on Data Inputs/Outputs DQ0-DQ7, otherwise 00h is output.

**Program Command.** The Program command can be used to program a value to one address in the memory array at a time. The command requires four Bus Write operations, the final write operation latches the address and data in the internal state machine and starts the Program/Erase Controller.

If the address falls in a protected block then the Program command is ignored, the data remains unchanged. The Status Register is never read and no error condition is given.

During the program operation the memory will ignore all commands. It is not possible to issue any command to abort or pause the operation. Typical program times are given in Table 4. Bus Read operations during the program operation will output the Status Register on the Data Inputs/Outputs. See the section on the Status Register for more details.

After the program operation has completed the memory will return to the Read mode, unless an error has occurred. When an error occurs the memory will continue to output the Status Register. A Read/Reset command must be issued to reset the error condition and return to Read mode.

Note that the Program command cannot change a bit set at '0' back to '1'. One of the Erase Commands must be used to set all the bits in a block or in the whole memory from '0' to '1'.

**Unlock Bypass Command.** The Unlock Bypass command is used in conjunction with the Unlock Bypass Program command to program the memory. When the cycle time to the device is long (as with some EPROM programmers) considerable time saving can be made by using these commands. Three Bus Write operations are required to issue the Unlock Bypass command.

Once the Unlock Bypass command has been issued the memory will only accept the Unlock Bypass Program command and the Unlock Bypass Reset command. The memory can be read as if in Read mode.

**Unlock Bypass Program Command.** The Unlock Bypass Program command can be used to program one address in the memory array at a time. The command requires two Bus Write operations, the final write operation latches the address and data in the internal state machine and starts the Program/Erase Controller.

The Program operation using the Unlock Bypass Program command behaves identically to the Program operation using the Program command. A protected block cannot be programmed; the operation cannot be aborted and the Status Register is read. Errors must be reset using the Read/Reset command, which leaves the device in Unlock Bypass Mode. See the Program command for details on the behavior.

**Unlock Bypass Reset Command.** The Unlock Bypass Reset command can be used to return to Read/Reset mode from Unlock Bypass Mode. Two Bus Write operations are required to issue the Unlock Bypass Reset command. Read/Reset

command does not exit from Unlock Bypass Mode.

**Chip Erase Command.** The Chip Erase command can be used to erase the entire chip. Six Bus Write operations are required to issue the Chip Erase Command and start the Program/Erase Controller.

If any blocks are protected then these are ignored and all the other blocks are erased. If all of the blocks are protected the Chip Erase operation appears to start but will terminate within about 100 $\mu$ s, leaving the data unchanged. No error condition is given when protected blocks are ignored.

During the erase operation the memory will ignore all commands, including the Erase Suspend command. It is not possible to issue any command to abort the operation. Typical chip erase times are given in Table 4. All Bus Read operations during the Chip Erase operation will output the Status Register on the Data Inputs/Outputs. See the section on the Status Register for more details.

After the Chip Erase operation has completed the memory will return to the Read Mode, unless an error has occurred. When an error occurs the memory will continue to output the Status Register. A Read/Reset command must be issued to reset the error condition and return to Read Mode.

The Chip Erase Command sets all of the bits in unprotected blocks of the memory to '1'. All previous data is lost.

**Block Erase Command.** The Block Erase command can be used to erase a list of one or more blocks. Six Bus Write operations are required to select the first block in the list. Each additional block in the list can be selected by repeating the sixth Bus Write operation using the address of the additional block. The Block Erase operation starts the Program/Erase Controller about 50 $\mu$ s after the last Bus Write operation. Once the Program/Erase Controller starts it is not possible to select any more blocks. Each additional block must therefore be selected within 50 $\mu$ s of the last block. The 50 $\mu$ s timer restarts when an additional block is selected. The Status Register can be read after the sixth Bus Write operation. See the Status Register section for details on how to identify if the Program/Erase Controller has started the Block Erase operation.

If any selected blocks are protected then these are ignored and all the other selected blocks are erased. If all of the selected blocks are protected the Block Erase operation appears to start but will terminate within about 100 $\mu$ s, leaving the data unchanged. No error condition is given when protected blocks are ignored.

During the Block Erase operation the memory will ignore all commands except the Erase Suspend

command. Typical block erase times are given in Table 4. All Bus Read operations during the Block Erase operation will output the Status Register on the Data Inputs/Outputs. See the section on the Status Register for more details.

After the Block Erase operation has completed the memory will return to the Read Mode, unless an error has occurred. When an error occurs the memory will continue to output the Status Register. A Read/Reset command must be issued to reset the error condition and return to Read mode.

The Block Erase Command sets all of the bits in the unprotected selected blocks to '1'. All previous data in the selected blocks is lost.

**Erase Suspend Command.** The Erase Suspend Command may be used to temporarily suspend a Block Erase operation and return the memory to Read mode. The command requires one Bus Write operation.

The Program/Erase Controller will suspend within 15 $\mu$ s of the Erase Suspend Command being issued. Once the Program/Erase Controller has stopped the memory will be set to Read mode and the Erase will be suspended. If the Erase Suspend command is issued during the period when the memory is waiting for an additional block (before the Program/Erase Controller starts) then the Erase is suspended immediately and will start immediately when the Erase Resume Command is issued. It is not possible to select any further blocks to erase after the Erase Resume. During Erase Suspend it is possible to Read and Program cells in blocks that are not being erased; both Read and Program operations behave as normal on these blocks. If any attempt is made to program in a protected block or in the suspended block then the Program command is ignored and the data remains unchanged. The Status Register is not read and no error condition is given. Reading from blocks that are being erased will output the Status Register.

It is also possible to issue the Auto Select, Read CFI Query and Unlock Bypass commands during an Erase Suspend. The Read/Reset command must be issued to return the device to Read Array mode before the Resume command will be accepted.

**Erase Resume Command.** The Erase Resume command must be used to restart the Program/Erase Controller after an Erase Suspend. The device must be in Read Array mode before the Resume command will be accepted. An erase can be suspended and resumed more than once.

**Read CFI Query Command.** The Read CFI Query Command is used to read data from the Common Flash Interface (CFI) Memory Area. This command is valid when the device is in the Read

Array mode, or when the device is in Autoselected mode.

One Bus Write cycle is required to issue the Read CFI Query Command. Once the command is issued subsequent Bus Read operations read from the Common Flash Interface Memory Area.

The Read/Reset command must be issued to return the device to the previous mode (the Read Array mode or Autoselected mode). A second Read/Reset command would be needed if the device is to be put in the Read Array mode from Autoselected mode.

See Appendix B, Tables 17, 18, 19, 20, 21 and 22 for details on the information contained in the Common Flash Interface (CFI) memory area.

**Block Protect and Chip Unprotect Commands.** Each block can be separately protected against accidental Program or Erase. The whole chip can be unprotected to allow the data inside the blocks to be changed.

Block Protect and Chip Unprotect operations are described in Appendix C.

**Table 3. Commands**

Command	Length	Bus Write Operations											
		1st		2nd		3rd		4th		5th		6th	
		Addr	Data	Addr	Data	Addr	Data	Addr	Data	Addr	Data	Addr	Data
Read/Reset	1	x	F0										
	3	x	AA	x	55	x	F0						
Auto Select	3	x	AA	x	55	x	90						
Program	4	x	AA	x	55	x	A0	PA	PD				
Unlock Bypass	3	x	AA	x	55	x	20						
Unlock Bypass Program	2	x	A0	PA	PD								
Unlock Bypass Reset	2	x	90	x	00								
Chip Erase	6	x	AA	x	55	x	80	x	AA	x	55	x	10
Block Erase	6+	x	AA	x	55	x	80	x	AA	x	55	BA	30
Erase Suspend	1	x	B0										
Erase Resume	1	x	30										
Read CFI Query	1	55	98										

Note: x Don't Care, PA Program Address, PD Program Data, BA Any address in the Block. All values in the table are in hexadecimal.

**Table 4. Program, Erase Times and Program, Erase Endurance Cycles**

Parameter	Min	Typ <sup>(1)</sup>	Typical after 100k W/E Cycles <sup>(1)</sup>	Max	Unit
Chip Erase		25	25	120	s
Block Erase (64 KBytes)		0.8		6	s
Program (Byte)		10		200	µs
Chip Program (Byte by Byte)		25		120	s
Program/Erase Cycles (per Block)	100,000				cycles

Note: 1.  $T_A = 25^\circ\text{C}$ ,  $V_{CC} = 3.3\text{V}$ .

## STATUS REGISTER

Bus Read operations from any address always read the Status Register during Program and Erase operations. It is also read during Erase Suspend when an address within a block being erased is accessed.

The bits in the Status Register are summarized in Table 5, Status Register Bits.

**Data Polling Bit (DQ7).** The Data Polling Bit can be used to identify whether the Program/Erase Controller has successfully completed its operation or if it has responded to an Erase Suspend. The Data Polling Bit is output on DQ7 when the Status Register is read.

During Program operations the Data Polling Bit outputs the complement of the bit being programmed to DQ7. After successful completion of the Program operation the memory returns to Read mode and Bus Read operations from the address just programmed output DQ7, not its complement.

During Erase operations the Data Polling Bit outputs '0', the complement of the erased state of DQ7. After successful completion of the Erase operation the memory returns to Read Mode.

In Erase Suspend mode the Data Polling Bit will output a '1' during a Bus Read operation within a block being erased. The Data Polling Bit will change from a '0' to a '1' when the Program/Erase Controller has suspended the Erase operation.

Figure 6, Data Polling Flowchart, gives an example of how to use the Data Polling Bit. A Valid Address is the address being programmed or an address within the block being erased.

**Toggle Bit (DQ6).** The Toggle Bit can be used to identify whether the Program/Erase Controller has successfully completed its operation or if it has responded to an Erase Suspend. The Toggle Bit is output on DQ6 when the Status Register is read.

During Program and Erase operations the Toggle Bit changes from '0' to '1' to '0', etc., with succes-

sive Bus Read operations at any address. After successful completion of the operation the memory returns to Read mode.

During Erase Suspend mode the Toggle Bit will output when addressing a cell within a block being erased. The Toggle Bit will stop toggling when the Program/Erase Controller has suspended the Erase operation.

If any attempt is made to erase a protected block, the operation is aborted, no error is signalled and DQ6 toggles for approximately 100µs. If any attempt is made to program a protected block or a suspended block, the operation is aborted, no error is signalled and DQ6 toggles for approximately 1µs.

Figure 7, Data Toggle Flowchart, gives an example of how to use the Data Toggle Bit.

**Error Bit (DQ5).** The Error Bit can be used to identify errors detected by the Program/Erase Controller. The Error Bit is set to '1' when a Program, Block Erase or Chip Erase operation fails to write the correct data to the memory. If the Error Bit is set a Read/Reset command must be issued before other commands are issued. The Error bit is output on DQ5 when the Status Register is read.

Note that the Program command cannot change a bit set to '0' back to '1' and attempting to do so will set DQ5 to '1'. A Bus Read operation to that address will show the bit is still '0'. One of the Erase commands must be used to set all the bits in a block or in the whole memory from '0' to '1'.

**Erase Timer Bit (DQ3).** The Erase Timer Bit can be used to identify the start of Program/Erase Controller operation during a Block Erase command. Once the Program/Erase Controller starts erasing the Erase Timer Bit is set to '1'. Before the Program/Erase Controller starts the Erase Timer Bit is set to '0' and additional blocks to be erased may be written to the Command Interface. The Erase Timer Bit is output on DQ3 when the Status Register is read.

**Alternative Toggle Bit (DQ2).** The Alternative Toggle Bit can be used to monitor the Program/Erase controller during Erase operations. The Alternative Toggle Bit is output on DQ2 when the Status Register is read.

During Chip Erase and Block Erase operations the Toggle Bit changes from '0' to '1' to '0', etc., with successive Bus Read operations from addresses within the blocks being erased. A protected block is treated the same as a block not being erased. Once the operation completes the memory returns to Read mode.

During Erase Suspend the Alternative Toggle Bit changes from '0' to '1' to '0', etc. with successive

Bus Read operations from addresses within the blocks being erased. Bus Read operations to addresses within blocks not being erased will output the memory cell data as if in Read mode.

After an Erase operation that causes the Error Bit to be set the Alternative Toggle Bit can be used to identify which block or blocks have caused the error. The Alternative Toggle Bit changes from '0' to '1' to '0', etc. with successive Bus Read Operations from addresses within blocks that have not erased correctly. The Alternative Toggle Bit does not change if the addressed block has erased correctly.

**Table 5. Status Register Bits**

Operation	Address	DQ7	DQ6	DQ5	DQ3	DQ2	R $\bar{B}$
Program	Any Address	$\overline{DQ7}$	Toggle	0	–	–	0
Program During Erase Suspend	Any Address	$\overline{DQ7}$	Toggle	0	–	–	0
Program Error	Any Address	$\overline{DQ7}$	Toggle	1	–	–	0
Chip Erase	Any Address	0	Toggle	0	1	Toggle	0
Block Erase before timeout	Erasing Block	0	Toggle	0	0	Toggle	0
	Non-Erasing Block	0	Toggle	0	0	No Toggle	0
Block Erase	Erasing Block	0	Toggle	0	1	Toggle	0
	Non-Erasing Block	0	Toggle	0	1	No Toggle	0
Erase Suspend	Erasing Block	1	No Toggle	0	–	Toggle	1
	Non-Erasing Block	Data read as normal					
Erase Error	Good Block Address	0	Toggle	1	1	No Toggle	0
	Faulty Block Address	0	Toggle	1	1	Toggle	0

Note: Unspecified data bits should be ignored.

Figure 6. Data Polling Flowchart

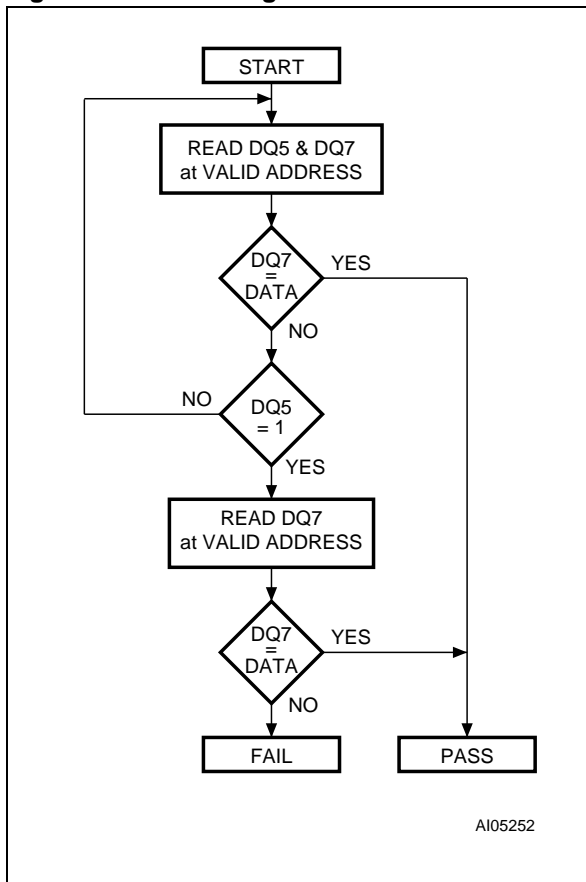

Figure 7. Data Toggle Flowchart

**MAXIMUM RATING**

Stressing the device above the rating listed in the Absolute Maximum Ratings table may cause permanent damage to the device. Exposure to Absolute Maximum Rating conditions for extended periods may affect device reliability. These are stress ratings only and operation of the device at

these or any other conditions above those indicated in the Operating sections of this specification is not implied. Refer also to the STMicroelectronics SURE Program and other relevant quality documents.

**Table 6. Absolute Maximum Ratings**

Symbol	Parameter	Min	Max	Unit
T <sub>BIAS</sub>	Temperature Under Bias	-50	125	°C
T <sub>STG</sub>	Storage Temperature	-65	150	°C
V <sub>IO</sub>	Input or Output Voltage <sup>(1,2)</sup>	-0.6	V <sub>CC</sub> +0.6	V
V <sub>CC</sub>	Supply Voltage	-0.6	4	V
V <sub>ID</sub>	Identification Voltage	-0.6	13.5	V

Note: 1. Minimum voltage may undershoot to -2V during transition and for less than 20ns during transitions.  
 2. Maximum voltage may overshoot to V<sub>CC</sub> +2V during transition and less than 20ns during transitions.

**DC AND AC PARAMETERS**

This section summarizes the operating measurement conditions, and the DC and AC characteristics of the device. The parameters in the DC and AC characteristics Tables that follow, are derived from tests performed under the Measurement

Conditions summarized in Table 7, Operating and AC Measurement Conditions. Designers should check that the operating conditions in their circuit match the operating conditions when relying on the quoted parameters.

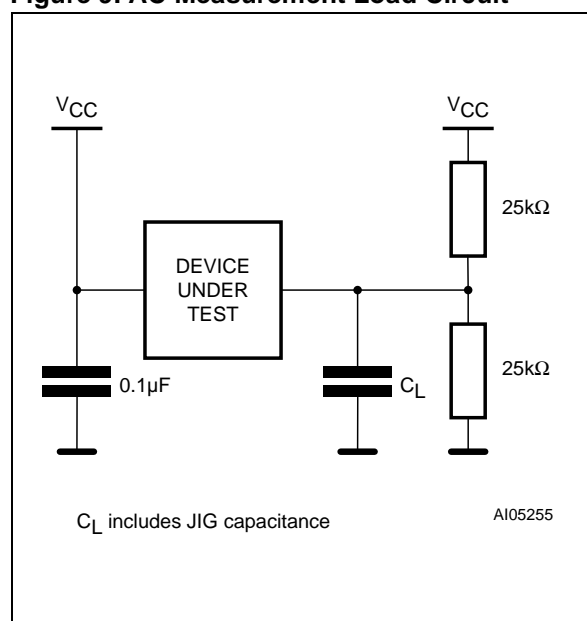

**Table 7. Operating and AC Measurement Conditions**

Parameter	M29W017D				Unit
	70		90		
	Min	Max	Min	Max	
V <sub>CC</sub> Supply Voltage	3.0	3.6	2.7	3.6	V
Ambient Operating Temperature	-40	85	-40	85	°C
Load Capacitance (C <sub>L</sub> )	30		100		pF
Input Rise and Fall Times		10		10	ns
Input Pulse Voltages	0 to V <sub>CC</sub>		0 to V <sub>CC</sub>		V
Input and Output Timing Ref. Voltages	V <sub>CC</sub> /2		V <sub>CC</sub> /2		V

## M29W017D

### PART NUMBERING

**Table 14. Ordering Information Scheme**

Example:	M29W017D	90	N	1	T
<b>Device Type</b> M29					
<b>Operating Voltage</b> W = V <sub>CC</sub> = 2.7 to 3.6V					
<b>Device Function</b> 017D = 16 Mbit (x8), Uniform Block					
<b>Speed</b> 70 = 70 ns 90 = 90 ns					
<b>Package</b> N = TSOP40: 10 x 20 mm ZA = TFBGA48: 0.80mm pitch					
<b>Temperature Range</b> 1 = 0 to 70 °C 6 = -40 to 85 °C					
<b>Option</b> T = Tape & Reel Packing					

Devices are shipped from the factory with the memory content bits erased to '1'.

For a list of available options (Speed, Package, etc...) or for further information on any aspect of this device, please contact the ST Sales Office nearest to you.

### REVISION HISTORY

**Table 15. Document Revision History**

Date	Version	Revision Details
May-2001	-01	First Issue (Brief Data)
18-Jun-2001	-02	Document expanded to full Product Preview, TFBGA Package Mechanical changed.
26-Jul-2001	-03	Document type: from Product Preview to Preliminary Data
03-Dec-2001	-04	Block Protection Appendix added, Read/Reset operation during Erase Suspend clarified .
05-Apr-2002	-05	Description of Ready/Busy signal clarified (and Figure 13 modified) Clarified allowable commands during block erase Clarified the mode the device returns to in the CFI Read Query command section

## APPENDIX B. COMMON FLASH INTERFACE (CFI)

The Common Flash Interface is a JEDEC approved, standardized data structure that can be read from the Flash memory device. It allows a system software to query the device to determine various electrical and timing parameters, density information and functions supported by the memory. The system can interface easily with the device, enabling the software to upgrade itself when necessary.

When the CFI Query Command is issued the device enters CFI Query mode and the data structure

is read from the memory. Tables 17, 18, 19, 20, 21 and 22 show the addresses used to retrieve the data.

The CFI data structure also contains a security area where a 64 bit unique security number is written (see Table 22, Security Code area). This area can be accessed only in Read mode by the final user. It is impossible to change the security number after it has been written by ST. Issue a Read/Reset command to return to Read mode.

**Table 17. Query Structure Overview**

Address	Sub-section Name	Description
10h	CFI Query Identification String	Command set ID and algorithm data offset
1Bh	System Interface Information	Device timing & voltage information
27h	Device Geometry Definition	Flash device layout
40h	Primary Algorithm-specific Extended Query table	Additional information specific to the Primary Algorithm (optional)
61h	Security Code Area	64 bit unique device number

Note: Query data are always presented on the lowest order data outputs.

**Table 18. CFI Query Identification String**

Address	Data	Description	Value
10h	51h	Query Unique ASCII String "QRY"	"Q"

68h	XX	

## APPENDIX C. BLOCK PROTECTION

Block protection can be used to prevent any operation from modifying the data stored in the Flash. Each Block can be protected individually. Once protected, Program and Erase operations on the block fail to change the data.

There are three techniques that can be used to control Block Protection, these are the Programmer technique, the In-System technique and Temporary Unprotection. Temporary Unprotection is controlled by the Reset/Block Temporary Unprotection pin,  $\overline{RP}$ ; this is described in the Signal Descriptions section.

Unlike the Command Interface of the Program/Erase Controller, the techniques for protecting and unprotecting blocks change between different Flash memory suppliers. For example, the techniques for AMD parts will not work on STMicroelectronics parts. Care should be taken when changing drivers for one part to work on another.

### Programmer Technique

The Programmer technique uses high ( $V_{ID}$ ) voltage levels on some of the bus pins. These cannot be achieved using a standard microprocessor bus, therefore the technique is recommended only for use in Programming Equipment.

To protect a block follow the flowchart in Figure 14, Programmer Equipment Block Protect Flowchart. To unprotect the whole chip it is necessary to protect all of the blocks first, then all blocks can be unprotected at the same time. To unprotect the chip follow Figure 15, Programmer Equipment Chip Unprotect Flowchart. Table 23, Programmer

Technique Bus Operations, gives a summary of each operation.

The timing on these flowcharts is critical. Care should be taken to ensure that, where a pause is specified, it is followed as closely as possible. Do not abort the procedure before reaching the end. Chip Unprotect can take several seconds and a user message should be provided to show that the operation is progressing.

### In-System Technique

The In-System technique requires a high voltage level on the Reset/Blocks Temporary Unprotect pin,  $\overline{RP}$ . This can be achieved without violating the maximum ratings of the components on the microprocessor bus, therefore this technique is suitable for use after the Flash has been fitted to the system.

To protect a block follow the flowchart in Figure 16, In-System Block Protect Flowchart. To unprotect the whole chip it is necessary to protect all of the blocks first, then all the blocks can be unprotected at the same time. To unprotect the chip follow Figure 17, In-System Chip Unprotect Flowchart.

The timing on these flowcharts is critical. Care should be taken to ensure that, where a pause is specified, it is followed as closely as possible. Do not allow the microprocessor to service interrupts that will upset the timing and do not abort the procedure before reaching the end. Chip Unprotect can take several seconds and a user message should be provided to show that the operation is progressing.

**Table 23. Programmer Technique Bus Operations,  $\overline{BYTE} = V_{IH}$  or  $V_{IL}$**

Operation	$\overline{E}$	$\overline{G}$	$\overline{W}$	Address Inputs A0-A20	Data Inputs/Outputs DQ15A-1, DQ14-DQ0
