

# ST72361

# 8-BIT MCU WITH FLASH OR ROM, 10-BIT ADC, 5 TIMERS, SPI, 2x LINSCI™

#### Memories

- 16K to 60K High Density Flash (HDFlash) or ROM with read-out protection capability. In-Application Programming and In-Circuit Programming for HDFlash devices
- 1.5 to 2K RAM
- HDFlash endurance: 100 cycles, data retention 40 years at 85°C

#### Clock, Reset and Supply Management

- Low power crystal/ceramic resonator oscillators and bypass for external clock
- PLL for 2x frequency multiplication
- 5 power saving modes: Halt, Auto Wake Up From Halt, Active Halt, Wait and Slow

## Interrupt Management

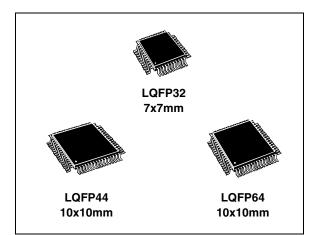

- Nested interrupt controller
- 14 interrupt vectors plus TRAP and RESET
- TLI top level interrupt (on 64-pin devices)
- Up to 21 external interrupt lines (on 4 vectors)

#### Up to 48 I/O Ports

- Up to 48 multifunctional bidirectional I/O lines
- Up to 36 alternate function lines
- Up to 6 high sink outputs

#### 5 Timers

- 16-bit timer with 2 input captures, 2 output compares, external clock input, PWM and pulse generator modes
- 8-bit timer with 1 or 2 input captures, 1 or 2 output compares, PWM and pulse generator modes
- 8-bit PWM auto-reload timer with 1 or 2 input captures, 2 or 4 independent PWM output channels, output compare and time base interrupt, external clock with event detector

- Main clock controller with real-time base and clock output
- Window watchdog timer

### Up to 3 Communications Interfaces

- SPI synchronous serial interface
- Master/slave LINSCI™ asynchronous serial interface
- Master-only LINSCI™ asynchronous serial interface
- Analog Peripheral (Low Current Coupling)
  - 10-bit A/D converter with up to 16 inputs
  - Up to 9 robust ports (low current coupling)

#### Instruction Set

- 8-bit data manipulation
- 63 basic instructions
- 17 main addressing modes
- 8 x 8 unsigned multiply instruction

#### Development Tools

Full hardware/software development package

#### Device Summary

Features	ST72(F)361(AR/J/K)9	ST72(F)361(AR/J/K)7	ST72(F)361(AR/J/K)6								
Program memory - bytes	60K	48K	32K								
RAM (stack) - bytes	2K (256)	2K (256)	1.5K (256)								
Operating Supply	4.5V to 5.5V										
CPU Frequency	External Resonator Osc. w/ PLLx2/8 MHz										
Max. Temp. Range	-40°C to +125°C										
Packages	LQFP64 10x10	mm (AR), LQFP44 10x10mm (J), LQF	LQFP64 10x10mm (AR), LQFP44 10x10mm (J), LQFP32 7x7mm (K)

# **1 INTRODUCTION**

The ST72361 devices are members of the ST7 microcontroller family designed for mid-range applications with LIN (Local Interconnect Network) interface.

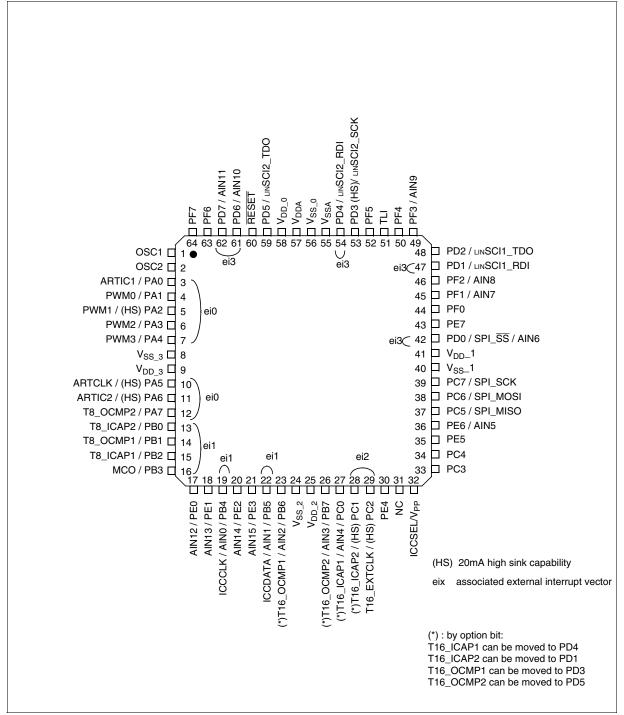

All devices are based on a common industrystandard 8-bit core, featuring an enhanced instruction set and are available with FLASH or ROM program memory. The enhanced instruction set and addressing modes of the ST7 offer both power and flexibility to software developers, enabling the design of highly efficient and compact application code. In addition to standard 8-bit data management, all ST7 microcontrollers feature true bit manipulation, 8x8 unsigned multiplication and indirect addressing modes.

# Figure 1. Device Block Diagram

# **2 PIN DESCRIPTION**

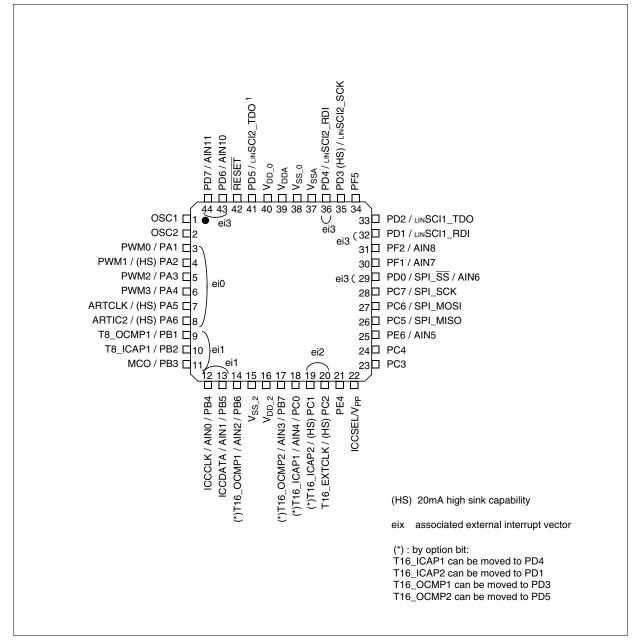

#### Figure 2. LQFP 64-Pin Package Pinout

# PIN DESCRIPTION (Cont'd)

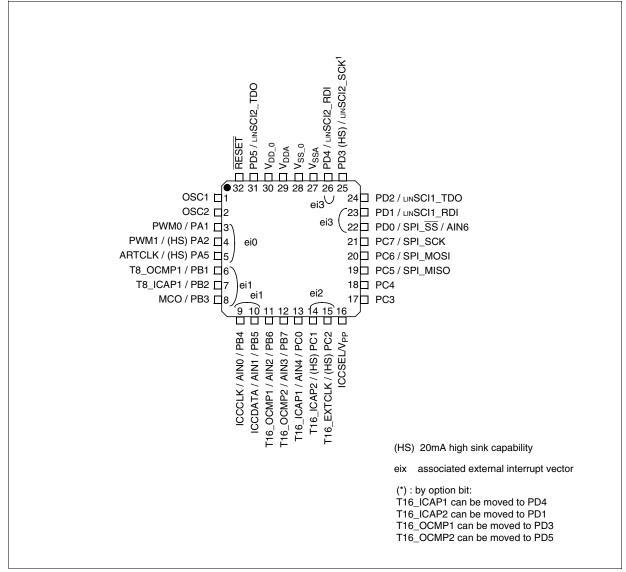

57.

# PIN DESCRIPTION (Cont'd)

For external pin connection guidelines, refer to "ELECTRICAL CHARACTERISTICS" on page 179.

# PIN DESCRIPTION (Cont'd)

For external pin connection guidelines, refer to "ELECTRICAL CHARACTERISTICS" on page 179.

# Legend / Abbreviations for Table 1:

Type: I = input, O = output, S = supply

In/Output level:  $C_T = CMOS \ 0.3V_{DD}/0.7V_{DD}$  with Schmitt trigger

T<sub>T</sub>= TTL 0.8V / 2V with Schmitt trigger

Output level: HS = 20mA high sink (on N-buffer only)

Port and control configuration:

- Input: float = floating, wpu = weak pull-up, int = interrupt<sup>1</sup>), ana = analog, RB = robust

- Output: OD = open drain, PP = push-pull

Refer to "I/O PORTS" on page 46 for more details on the software configuration of the I/O ports.

The RESET configuration of each pin is shown in bold which is valid as long as the device is in reset state.

#### Notes:

<u>/</u>کا

1. In the interrupt input column, "eiX" defines the associated external interrupt vector. If the weak pull-up column (wpu) is merged with the interrupt column (int), then the I/O configuration is pull-up interrupt input, else the configuration is floating interrupt input.

2. Input mode can be used for general purpose I/O, output mode cannot be used.

3. OSC1 and OSC2 pins connect a crystal/ceramic resonator, or an external source to the on-chip oscillator; see Section 1 and Section 12.5 "CLOCK AND TIMING CHARACTERISTICS" for more details.

4. On the chip, each I/O port has eight pads. Pads that are not bonded to external pins are in input pull-up configuration after reset. The configuration of these pads must be kept at reset state to avoid added current consumption.

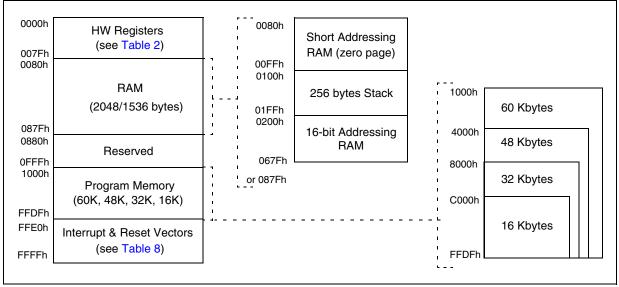

# **3 REGISTER AND MEMORY MAP**

As shown in Figure 5, the MCU is capable of addressing 64 Kbytes of memories and I/O registers.

The available memory locations consist of 128 bytes of register locations, up to 2 Kbytes of RAM and up to 60 Kbytes of user program memory.

The RAM space includes up to 256 bytes for the stack from 0100h to 01FFh.The highest address bytes contain the user reset and interrupt vectors.

**IMPORTANT:** Memory locations marked as "Reserved" must never be accessed. Accessing a reseved area can have unpredictable effects on the device.

#### Figure 5. Memory Map

**Legend**: x = undefined, R/W = read/write

Notes:

1. The contents of the I/O port DR registers are readable only in output configuration. In input configuration, the values of the I/O pins are returned instead of the DR register contents.

2. The bits associated with unavailable pins must always keep their reset value.

# 4 FLASH PROGRAM MEMORY

# **4.1 INTRODUCTION**

The ST7 dual voltage High Density Flash (HDFlash) is a non-volatile memory that can be electrically erased as a single block or by individual sectors and programmed on a Byte-by-Byte basis using an external  $V_{PP}$  supply.

The HDFlash devices can be programmed and erased off-board (plugged in a programming tool) or on-board using ICP (In-Circuit Programming) or IAP (In-Application Programming).

The array matrix organisation allows each sector to be erased and reprogrammed without affecting other sectors.

# **4.2 MAIN FEATURES**

- 3 Flash programming modes:
  - Insertion in a programming tool. In this mode, all sectors including option bytes can be programmed or erased.
  - ICP (In-Circuit Programming). In this mode, all sectors including option bytes can be programmed or erased without removing the device from the application board.
  - IAP (In-Application Programming) In this mode, all sectors except Sector 0, can be programmed or erased without removing the device from the application board and while the application is running.
- ICT (In-Circuit Testing) for downloading and executing user application test patterns in RAM
- Read-out protection
- Register Access Security System (RASS) to prevent accidental programming or erasing

# **4.3 STRUCTURE**

The Flash memory is organised in sectors and can be used for both code and data storage.

Depending on the overall Flash memory size in the microcontroller device, there are up to three user sectors (see Table 1). Each of these sectors can be erased independently to avoid unnecessary erasing of the whole Flash memory when only a partial erasing is required.

The first two sectors have a fixed size of 4 Kbytes (see Figure 1). They are mapped in the upper part of the ST7 addressing space so the reset and interrupt vectors are located in Sector 0 (F000h-FFFFh).

Table 3. Sectors available in Flash devices	tors available in Flash devices
---	---------------------------------

Flash Size (bytes)	Available Sectors
4K	Sector 0
8K	Sectors 0,1
> 8K	Sectors 0,1, 2

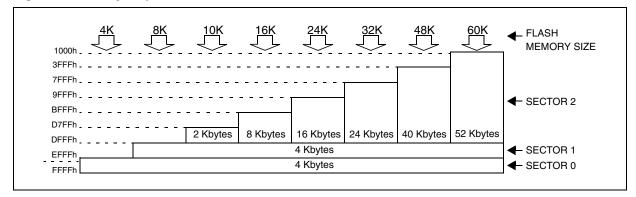

#### 4.3.1 Read-out Protection

Read-out protection, when selected, provides a protection against Program Memory content extraction and against write access to Flash memory. Even if no protection can be considered as totally unbreakable, the feature provides a very high level of protection for a general purpose microcontroller.

In Flash devices, this protection is removed by reprogramming the option. In this case, the entire program memory is first automatically erased and the device can be reprogrammed.

Read-out protection selection depends on the device type:

- In Flash devices it is enabled and removed through the FMP\_R bit in the option byte.
- In ROM devices it is enabled by mask option specified in the Option List.

# Figure 6. Memory Map and Sector Address

# FLASH PROGRAM MEMORY (Cont'd)

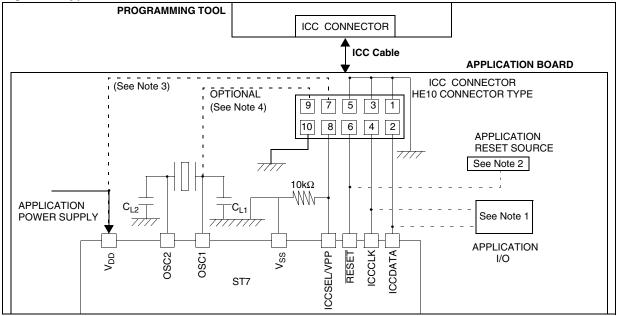

# **4.4 ICC INTERFACE**

ICC (In-Circuit Communication) needs a minimum of four and up to six pins to be connected to the programming tool (see Figure 2). These pins are:

- RESET: device reset
- V<sub>SS</sub>: device power supply ground

#### Figure 7. Typical ICC Interface

- ICCCLK: ICC output serial clock pin
- ICCDATA: ICC input/output serial data pin
- ICCSEL/V<sub>PP</sub>: programming voltage
- OSC1(or OSCIN): main clock input for external source (optional)
- V<sub>DD</sub>: application board power supply (see Figure 2, Note 3)

#### Notes:

1. If the ICCCLK or ICCDATA pins are only used as outputs in the application, no signal isolation is necessary. As soon as the Programming Tool is plugged to the board, even if an ICC session is not in progress, the ICCCLK and ICCDATA pins are not available for the application. If they are used as inputs by the application, isolation such as a serial resistor has to implemented in case another device forces the signal. Refer to the Programming Tool documentation for recommended resistor values.

2. During the IC<u>C</u> session, the programming tool must control the RESET pin. This can lead to conflicts between the programming tool and the application reset circuit if it drives more than 5mA at high level (push pull output or pull-up resistor<1K). A schottky diode can be used to isolate the application RESET circuit in this case. When using a classical RC network with R > 1K or a reset man-

agement IC with open drain output and pull-up resistor > 1K, no additional components are needed. In all cases the user must ensure that no external reset is generated by the application during the ICC session.

3. The use of Pin 7 of the ICC connector depends on the Programming Tool architecture. This pin must be connected when using most ST Programming Tools (it is used to monitor the application power supply). Please refer to the Programming Tool manual.

4. Pin 9 has to be connected to the OSC1 or OS-CIN pin of the ST7 when the clock is not available in the application or if the selected clock option is not programmed in the option byte. ST7 devices with multi-oscillator capability need to have OSC2 grounded in this case.

# FLASH PROGRAM MEMORY (Cont'd)

# 4.5 ICP (IN-CIRCUIT PROGRAMMING)

To perform ICP the microcontroller must be switched to ICC (In-Circuit Communication) mode by an external controller or programming tool.

Depending on the ICP code downloaded in RAM, Flash memory programming can be fully customized (number of bytes to program, program locations, or selection serial communication interface for downloading).

When using an STMicroelectronics or third-party programming tool that supports ICP and the specific microcontroller device, the user needs only to implement the ICP hardware interface on the application board (see Figure 2). For more details on the pin locations, refer to the device pinout description.

### 4.6 IAP (IN-APPLICATION PROGRAMMING)

This mode uses a BootLoader program previously stored in Sector 0 by the user (in ICP mode or by plugging the device in a programming tool).

This mode is fully controlled by user software. This allows it to be adapted to the user application, (user-defined strategy for entering programming mode, choice of communications protocol used to fetch the data to be stored, etc.). For example, it is possible to download code from the SPI, SCI or other type of serial interface and program it in the Flash. IAP mode can be used to program any of the Flash sectors except Sector 0, which is write/ erase protected to allow recovery in case errors occur during the programming operation.

Reset Value

## **4.7 RELATED DOCUMENTATION**

For details on Flash programming and ICC protocol, refer to the *ST7 Flash Programming Reference Manual* and to the *ST7 ICC Protocol Reference Manual*.

#### **4.8 REGISTER DESCRIPTION**

## FLASH CONTROL/STATUS REGISTER (FCSR)

Read/Write

Reset Value: 0000 0000 (00h)

7							0
0	0	0	0	0	0	0	0

This register is reserved for use by Programming Tool software. It controls the Flash programming and erasing operations.

# **5 CENTRAL PROCESSING UNIT**

# **5.1 INTRODUCTION**

This CPU has a full 8-bit architecture and contains six internal registers allowing efficient 8-bit data manipulation.

## **5.2 MAIN FEATURES**

- Enable executing 63 basic instructions
- Fast 8-bit by 8-bit multiply
- 17 main addressing modes (with indirect addressing mode)
- Two 8-bit index registers
- 16-bit stack pointer
- Low power HALT and WAIT modes
- Priority maskable hardware interrupts
- Non-maskable software/hardware interrupts

#### **5.3 CPU REGISTERS**

The six CPU registers shown in Figure 1 are not present in the memory mapping and are accessed by specific instructions.

#### Accumulator (A)

The Accumulator is an 8-bit general purpose register used to hold operands and the results of the arithmetic and logic calculations and to manipulate data.

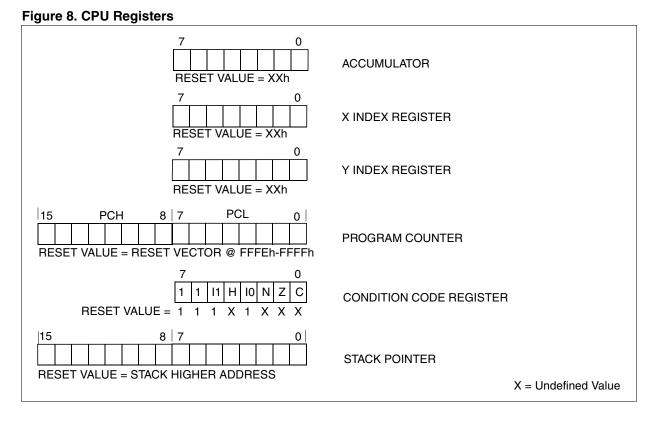

#### Index Registers (X and Y)

These 8-bit registers are used to create effective addresses or as temporary storage areas for data manipulation. (The Cross-Assembler generates a precede instruction (PRE) to indicate that the following instruction refers to the Y register.)

The Y register is not affected by the interrupt automatic procedures.

#### Program Counter (PC)

The program counter is a 16-bit register containing the address of the next instruction to be executed by the CPU. It is made of two 8-bit registers PCL (Program Counter Low which is the LSB) and PCH (Program Counter High which is the MSB).

# CENTRAL PROCESSING UNIT (Cont'd)

# Condition Code Register (CC)

Read/Write

Reset Value: 111x1xxx

The 8-bit Condition Code register contains the interrupt masks and four flags representative of the result of the instruction just executed. This register can also be handled by the PUSH and POP instructions.

These bits can be individually tested and/or controlled by specific instructions.

### Arithmetic Management Bits

#### Bit 4 = **H** Half carry.

This bit is set by hardware when a carry occurs between bits 3 and 4 of the ALU during an ADD or ADC instructions. It is reset by hardware during the same instructions.

0: No half carry has occurred.

1: A half carry has occurred.

This bit is tested using the JRH or JRNH instruction. The H bit is useful in BCD arithmetic subroutines.

#### Bit 2 = N Negative.

This bit is set and cleared by hardware. It is representative of the result sign of the last arithmetic, logical or data manipulation. It's a copy of the result  $7^{th}$  bit.

0: The result of the last operation is positive or null.

1: The result of the last operation is negative (that is, the most significant bit is a logic 1).

This bit is accessed by the JRMI and JRPL instructions.

## Bit 1 = **Z** Zero.

This bit is set and cleared by hardware. This bit indicates that the result of the last arithmetic, logical or data manipulation is zero.

0: The result of the last operation is different from zero.

1: The result of the last operation is zero.

This bit is accessed by the JREQ and JRNE test instructions.

## Bit 0 = C Carry/borrow.

This bit is set and cleared by hardware and software. It indicates an overflow or an underflow has occurred during the last arithmetic operation.

0: No overflow or underflow has occurred.

1: An overflow or underflow has occurred.

This bit is driven by the SCF and RCF instructions and tested by the JRC and JRNC instructions. It is also affected by the "bit test and branch", shift and rotate instructions.

# **Interrupt Management Bits**

#### Bit 5,3 = 11, 10 Interrupt

The combination of the I1 and I0 bits gives the current interrupt software priority.

Interrupt Software Priority	1	10
Level 0 (main)	1	0
Level 1	0	1
Level 2	0	0
Level 3 (= interrupt disable)	1	1

These two bits are set/cleared by hardware when entering in interrupt. The loaded value is given by the corresponding bits in the interrupt software priority registers (IxSPR). They can be also set/ cleared by software with the RIM, SIM, IRET, HALT, WFI and PUSH/POP instructions.

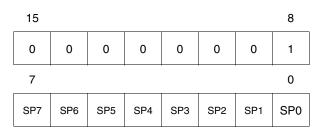

See the interrupt management chapter for more details.

# CENTRAL PROCESSING UNIT (Cont'd)

Stack Pointer (SP)

Read/Write

Reset Value: 01 FFh

The Stack Pointer is a 16-bit register which is always pointing to the next free location in the stack. It is then decremented after data has been pushed onto the stack and incremented before data is popped from the stack (see Figure 2).

Since the stack is 256 bytes deep, the 8 most significant bits are forced by hardware. Following an MCU Reset, or after a Reset Stack Pointer instruction (RSP), the Stack Pointer contains its reset value (the SP7 to SP0 bits are set) which is the stack higher address.

Figure 9. Stack Manipulation Example

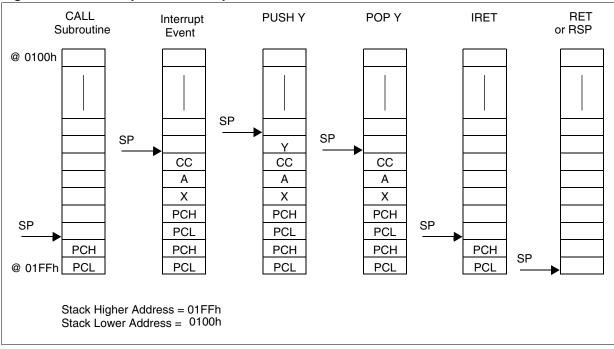

The least significant byte of the Stack Pointer (called S) can be directly accessed by a LD instruction.

**Note:** When the lower limit is exceeded, the Stack Pointer wraps around to the stack upper limit, without indicating the stack overflow. The previously stored information is then overwritten and therefore lost. The stack also wraps in case of an underflow.

The stack is used to save the return address during a subroutine call and the CPU context during an interrupt. The user may also directly manipulate the stack by means of the PUSH and POP instructions. In the case of an interrupt, the PCL is stored at the first location pointed to by the SP. Then the other registers are stored in the next locations as shown in Figure 2.

- When an interrupt is received, the SP is decremented and the context is pushed on the stack.
- On return from interrupt, the SP is incremented and the context is popped from the stack.

A subroutine call occupies two locations and an interrupt five locations in the stack area.

# **6 SUPPLY, RESET AND CLOCK MANAGEMENT**

The device includes a range of utility features for securing the application in critical situations (for example, in case of a power brown-out), and reducing the number of external components. An overview is shown in Figure 11.

For more details, refer to dedicated parametric section.

#### Main features

57/

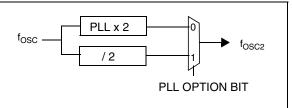

- Optional PLL for multiplying the frequency by 2
- Reset Sequence Manager (RSM)
- Multi-Oscillator Clock Management (MO)
  - 4 Crystal/Ceramic resonator oscillators
- System Integrity Management (SI)
  - Main supply Low voltage detection (LVD)
  - Auxiliary Voltage detector (AVD) with interrupt capability for monitoring the main supply

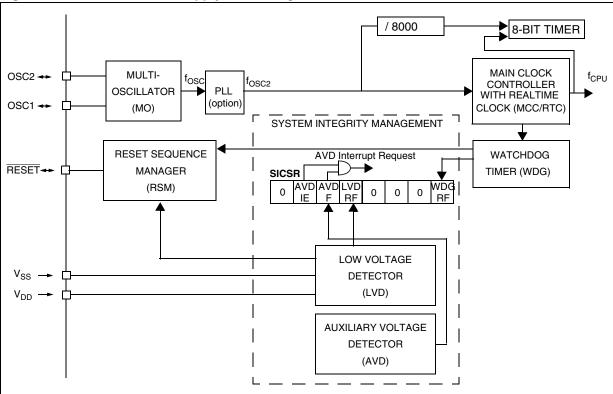

# 6.1 PHASE LOCKED LOOP

If the clock frequency input to the PLL is in the range 2 to 4 MHz, the PLL can be used to multiply the frequency by two to obtain an  $f_{OSC2}$  of 4 to 8 MHz. The PLL is enabled by option byte. If the PLL is disabled, then  $f_{OSC2} = f_{OSC}/2$ .

**Caution:** The PLL is not recommended for applications where timing accuracy is required. See "PLL Characteristics" on page 188.

### Figure 10. PLL Block Diagram

# Figure 11. Clock, Reset and Supply Block Diagram

# 6.2 MULTI-OSCILLATOR (MO)

The main clock of the ST7 can be generated by two different source types coming from the multioscillator block:

- an external source
- a crystal or ceramic resonator oscillator

Each oscillator is optimized for a given frequency range in terms of consumption and is selectable through the option byte. The associated hardware configuration are shown in Table 5. Refer to the electrical characteristics section for more details.

**Caution:** The OSC1 and/or OSC2 pins must not be left unconnected. For the purposes of Failure Mode and Effect Analysis, it should be noted that if the OSC1 and/or OSC2 pins are left unconnected, the ST7 main oscillator may start and, in this configuration, could generate an  $f_{OSC}$  clock frequency in excess of the allowed maximum (> 16 MHz), putting the ST7 in an unsafe/undefined state. The product behavior must therefore be considered undefined when the OSC pins are left unconnected.

#### **External Clock Source**

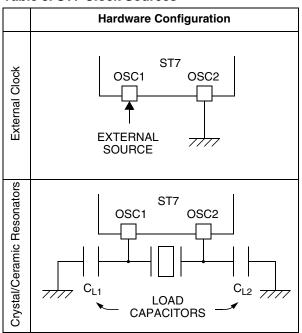

In external clock mode, a clock signal (square, sinus or triangle) with ~50% duty cycle has to drive the OSC1 pin while the OSC2 pin is tied to ground.

#### **Crystal/Ceramic Oscillators**

This family of oscillators has the advantage of producing a very accurate rate on the main clock of the ST7. The selection within a list of five oscillators with different frequency ranges must be done by option byte in order to reduce consumption (refer to Section 14.1 on page 210 for more details on the frequency ranges). The resonator and the load capacitors must be placed as close as possible to the oscillator pins in order to minimize output distortion and start-up stabilization time. The loading capacitance values must be adjusted according to the selected oscillator.

These oscillators are not stopped during the RESET phase to avoid losing time in the oscillator start-up phase.

Table 5. ST7 Clock Sources

# 6.3 RESET SEQUENCE MANAGER (RSM)

#### 6.3.1 Introduction

The reset sequence manager includes three RE-SET sources as shown in Figure 2:

- External RESET source pulse
- Internal LVD RESET (Low Voltage Detection)
- Internal WATCHDOG RESET

These sources act on the RESET pin and it is always kept low during the delay phase.

The RESET service routine vector is fixed at addresses FFFEh-FFFFh in the ST7 memory map.

The basic RESET sequence consists of three phases as shown in Figure 1:

- Active Phase depending on the RESET source
- 256 or 4096 CPU clock cycle delay (selected by option byte)
- RESET vector fetch

5/

The 256 or 4096 CPU clock cycle delay allows the oscillator to stabilize and ensures that recovery has taken place from the Reset state. The shorter or longer clock cycle delay should be selected by option byte to correspond to the stabilization time of the external oscillator used in the application.

### Figure 13. Reset Block Diagram

The RESET vector fetch phase duration is two clock cycles.

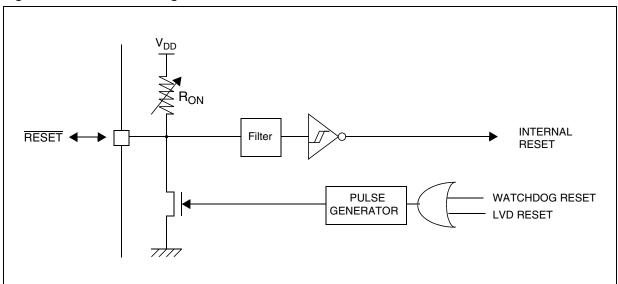

# Figure 12. RESET Sequence Phases

	RESET	
Active Phase	INTERNAL RESET 256 or 4096 CLOCK CYCLES	FETCH VECTOR

#### 6.3.2 Asynchronous External RESET pin

The  $\overline{\text{RESET}}$  pin is both an input and an open-drain output with integrated  $R_{ON}$  weak pull-up resistor. This pull-up has no fixed value but varies in accordance with the input voltage. It can be pulled low by external circuitry to reset the device. See Electrical Characteristic section for more details.

A RESET signal originating from an external source must have a duration of at least  $t_{h(RSTL)in}$  in order to be recognized (see Figure 3). This detection is asynchronous and therefore the MCU can enter reset state even in HALT mode.

# RESET SEQUENCE MANAGER (Cont'd)

The **RESET** pin is an asynchronous signal which plays a major role in EMS performance. In a noisy environment, it is recommended to follow the guidelines mentioned in the electrical characteristics section.

#### 6.3.3 External Power-On RESET

If the LVD is disabled by option byte, to start up the microcontroller correctly, the user must ensure by means of an external reset circuit that the reset signal is held low until  $V_{DD}$  is over the minimum level specified for the selected  $f_{OSC}$  frequency.

A proper reset signal for a slow rising  $V_{DD}$  supply can generally be provided by an external RC network connected to the RESET pin.

# 6.3.4 Internal Low Voltage Detector (LVD) RESET

Two different RESET sequences caused by the internal LVD circuitry can be distinguished:

- Power-On RESET
- Voltage Drop RESET

The device  $\overrightarrow{\text{RESET}}$  pin acts as an output that is pulled low when  $V_{DD} < V_{IT+}$  (rising edge) or  $V_{DD} < V_{IT-}$  (falling edge) as shown in Figure 3.

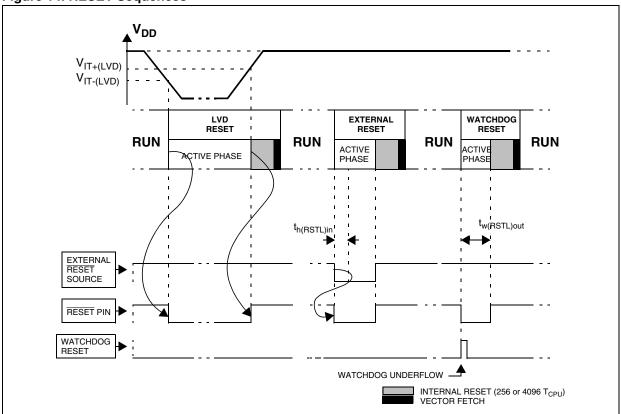

The LVD filters spikes on  $V_{DD}$  larger than  $t_{g(VDD)}$  to avoid parasitic resets.

#### 6.3.5 Internal Watchdog RESET

The RESET sequence generated by a internal Watchdog counter overflow is shown in Figure 3.

Starting from the Watchdog counter underflow, the device RESET pin acts as an output that is pulled low during at least  $t_{w(RSTL)out}$ .

457/

# Figure 14. RESET Sequences

# 6.4 SYSTEM INTEGRITY MANAGEMENT (SI)

The System Integrity Management block contains the Low Voltage Detector (LVD) and Auxiliary Voltage Detector (AVD) functions. It is managed by the SICSR register.

#### 6.4.1 Low Voltage Detector (LVD)

The Low Voltage Detector function (LVD) generates a static reset when the V<sub>DD</sub> supply voltage is below a V<sub>IT-(LVD)</sub> reference value. This means that it secures the power-up as well as the power-down keeping the ST7 in reset.

The  $V_{IT\mathchar`(LVD)}$  reference value for a voltage drop is lower than the  $V_{IT\mathchar`(LVD)}$  reference value for poweron in order to avoid a parasitic reset when the MCU starts running and sinks current on the supply (hysteresis).

The LVD Reset circuitry generates a reset when  $V_{\text{DD}}$  is below:

- $V_{IT+(LVD)}$  when  $V_{DD}$  is rising
- $-V_{IT-(LVD)}$  when  $V_{DD}$  is falling

57/

The LVD function is illustrated in Figure 15.

#### Figure 15. Low Voltage Detector vs Reset

Provided the minimum  $V_{DD}$  value (guaranteed for the oscillator frequency) is above  $V_{IT\mathchar`(LVD)},$  the MCU can only be in two modes:

- under full software control

- in static safe reset

In these conditions, secure operation is always ensured for the application without the need for external reset hardware.

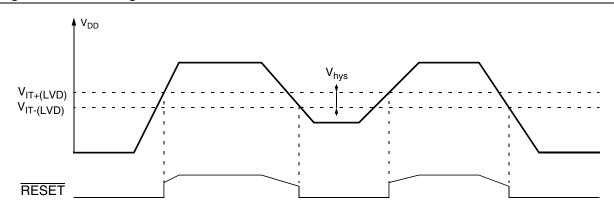

During a Low Voltage Detector Reset, the RESET pin is held low, thus permitting the MCU to reset other devices.

#### Notes:

The LVD allows the device to be used without any external RESET circuitry.

The LVD is an optional function which can be selected by option byte.

It is recommended to make sure that the  $V_{DD}$  supply voltage rises monotonously when the device is exiting from Reset, to ensure the application functions properly.

# SYSTEM INTEGRITY MANAGEMENT (Cont'd)

## 6.4.2 Auxiliary Voltage Detector (AVD)

The Voltage Detector function (AVD) is based on an analog comparison between a  $V_{IT-(AVD)}$  and  $V_{IT+(AVD)}$  reference value and the  $V_{DD}$  main supply. The  $V_{IT-(AVD)}$  reference value for falling voltage is lower than the  $V_{IT+(AVD)}$  reference value for rising voltage in order to avoid parasitic detection (hysteresis).

The output of the AVD comparator is directly readable by the application software through a real time status bit (AVDF) in the SICSR register. This bit is read only.

**Caution**: The AVD function is active only if the LVD is enabled through the option byte.

#### 6.4.2.1 Monitoring the V<sub>DD</sub> Main Supply

If the AVD interrupt is enabled, an interrupt is generated when the voltage crosses the  $V_{IT+(AVD)}$  or  $V_{IT-(AVD)}$  threshold (AVDF bit toggles).

In the case of a drop in voltage, the AVD interrupt acts as an early warning, allowing software to shut

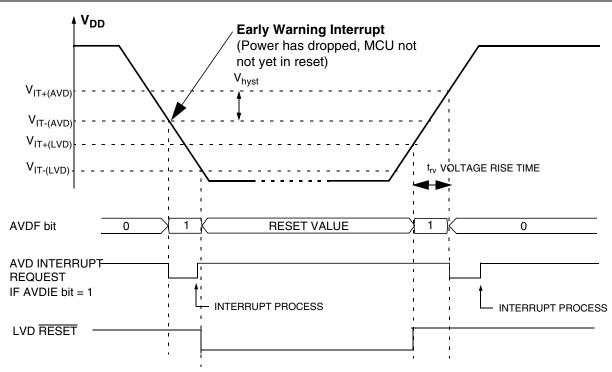

down safely before the LVD resets the microcontroller. See Figure 16.

The interrupt on the rising edge is used to inform the application that the  $V_{DD}$  warning state is over.

If the voltage rise time  $t_{rv}$  is less than 256 or 4096 CPU cycles (depending on the reset delay selected by option byte), no AVD interrupt will be generated when  $V_{\rm IT+(AVD)}$  is reached.

If t<sub>rv</sub> is greater than 256 or 4096 cycles then:

- If the AVD interrupt is enabled before the V<sub>IT+(AVD)</sub> threshold is reached, then two AVD interrupts will be received: The first when the AVDIE bit is set and the second when the threshold is reached.
- If the AVD interrupt is enabled after the V<sub>IT+(AVD)</sub> threshold is reached, then only one AVD interrupt occurs.

#### Figure 16. Using the AVD to Monitor V<sub>DD</sub>

# SYSTEM INTEGRITY MANAGEMENT (Cont'd)

## 6.4.3 Low Power Modes

Mode Description					
WAIT	No effect on SI. AVD interrupts cause the device to exit from Wait mode.				
HALT	The SICSR register is frozen.				

# 6.4.3.1 Interrupts

57

The AVD interrupt event generates an interrupt if the AVDIE bit is set and the interrupt mask in the CC register is reset (RIM instruction).

Interrupt Event	Event Flag	Enable Control Bit	Exit from Wait	Exit from Halt
AVD event	AVDF	AVDIE	Yes	No

# SYSTEM INTEGRITY MANAGEMENT (Cont'd)

#### 6.4.4 Register Description

## SYSTEM INTEGRITY (SI) CONTROL/STATUS REGISTER (SICSR)

#### Read/Write

Reset Value: 000x 000x (00h)

7							0
0	AVD IE	AVD F	LVD RF	0	0	0	WDG RF

Bit 7 = Reserved, must be kept cleared.

Bit 6 = **AVDIE** Voltage Detector interrupt enable This bit is set and cleared by software. It enables an interrupt to be generated when the AVDF flag changes (toggles). The pending interrupt information is automatically cleared when software enters the AVD interrupt routine.

0: AVD interrupt disabled

1: AVD interrupt enabled

#### Bit 5 = **AVDF** Voltage Detector flag

This read-only bit is set and cleared by hardware. If the AVDIE bit is set, an interrupt request is generated when the AVDF bit changes value. Refer to Figure 16 and to Section 6.4.2.1 for additional details.

0:  $V_{DD}$  over  $V_{IT+(AVD)}$  threshold

1: V<sub>DD</sub> under V<sub>IT-(AVD)</sub> threshold

#### Bit 4 = LVDRF LVD reset flag

This bit indicates that the last Reset was generated by the LVD block. It is set by hardware (LVD reset) and cleared by software (writing zero). See WDGRF flag description for more details. When the LVD is disabled by OPTION BYTE, the LVDRF bit value is undefined. Bits 3:1 = Reserved, must be kept cleared.

#### Bit 0 = **WDGRF** Watchdog reset flag

This bit indicates that the last Reset was generated by the Watchdog peripheral. It is set by hardware (watchdog reset) and cleared by software (writing zero) or an LVD Reset (to ensure a stable cleared state of the WDGRF flag when CPU starts).

Combined with the LVDRF flag information, the flag description is given by the following table.

RESET Sources	LVDRF	WDGRF
External RESET pin	0	0
Watchdog	0	1
LVD	1	Х

#### Application notes

The LVDRF flag is not cleared when another RE-SET type occurs (external or watchdog), the LVDRF flag remains set to keep trace of the original failure.

In this case, a watchdog reset can be detected by software while an external reset can not.

**CAUTION:** When the LVD is not activated with the associated option byte, the WDGRF flag can not be used in the application.

# **7 INTERRUPTS**

# 7.1 INTRODUCTION

The ST7 enhanced interrupt management provides the following features:

- Hardware interrupts
- Software interrupt (TRAP)
- Nested or concurrent interrupt management with flexible interrupt priority and level management:
  - Up to 4 software programmable nesting levels
  - Up to 16 interrupt vectors fixed by hardware
  - 2 non maskable events: RESET, TRAP
  - 1 maskable Top Level Event: TLI

This interrupt management is based on:

- Bit 5 and bit 3 of the CPU CC register (11:0),
- Interrupt software priority registers (ISPRx),
- Fixed interrupt vector addresses located at the high addresses of the memory map (FFE0h to FFFFh) sorted by hardware priority order.

This enhanced interrupt controller guarantees full upward compatibility with the standard (not nested) ST7 interrupt controller.

# 7.2 MASKING AND PROCESSING FLOW

The interrupt masking is managed by the I1 and I0 bits of the CC register and the ISPRx registers which give the interrupt software priority level of

Figure 17. Interrupt Processing Flowchart

each interrupt vector (see Table 1). The processing flow is shown in Figure 1.

When an interrupt request has to be serviced:

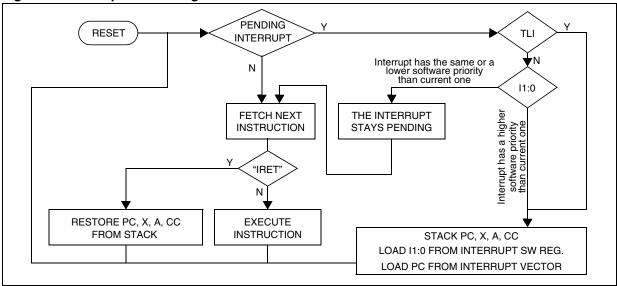

- Normal processing is suspended at the end of the current instruction execution.
- The PC, X, A and CC registers are saved onto the stack.
- I1 and I0 bits of CC register are set according to the corresponding values in the ISPRx registers of the serviced interrupt vector.
- The PC is then loaded with the interrupt vector of the interrupt to service and the first instruction of the interrupt service routine is fetched (refer to "Interrupt Mapping" table for vector addresses).

The interrupt service routine should end with the IRET instruction which causes the contents of the saved registers to be recovered from the stack.

**Note**: As a consequence of the IRET instruction, the I1 and I0 bits will be restored from the stack and the program in the previous level will resume.

### Table 6. Interrupt Software Priority Levels

Interrupt software priority	Level	l1	10
Level 0 (main)	Low	1	0
Level 1		0	1
Level 2	🔸	0	0
Level 3 (= interrupt disable)	High	1	1

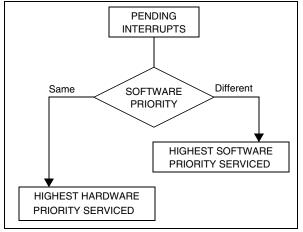

### **Servicing Pending Interrupts**

As several interrupts can be pending at the same time, the interrupt to be taken into account is determined by the following two-step process:

- the highest software priority interrupt is serviced,
- if several interrupts have the same software priority then the interrupt with the highest hardware priority is serviced first.
- Figure 2 describes this decision process.

### Figure 18. Priority Decision Process

When an interrupt request is not serviced immediately, it is latched and then processed when its software priority combined with the hardware priority becomes the highest one.

**Note 1**: The hardware priority is exclusive while the software one is not. This allows the previous process to succeed with only one interrupt.

**Note 2**: RESET, TRAP and TLI can be considered as having the highest software priority in the decision process.

#### **Different Interrupt Vector Sources**

Two interrupt source types are managed by the ST7 interrupt controller: the non-maskable type (RESET, TRAP) and the maskable type (external or from internal peripherals).

#### Non-Maskable Sources

These sources are processed regardless of the state of the 11 and 10 bits of the CC register (see Figure 1). After stacking the PC, X, A and CC registers (except for RESET), the corresponding vector is loaded in the PC register and the 11 and 10 bits of the CC are set to disable interrupts (level 3). These sources allow the processor to exit HALT mode.

TRAP (Non Maskable Software Interrupt)

This software interrupt is serviced when the TRAP instruction is executed. It will be serviced according to the flowchart in Figure 1 as a TLI.

Caution: TRAP can be interrupted by a TLI.

RESET

The RESET source has the highest priority in the ST7. This means that the first current routine has the highest software priority (level 3) and the highest hardware priority.

See the RESET chapter for more details.

#### Maskable Sources

Maskable interrupt vector sources can be serviced if the corresponding interrupt is enabled and if its own interrupt software priority (in ISPRx registers) is higher than the one currently being serviced (I1 and I0 in CC register). If any of these two conditions is false, the interrupt is latched and thus remains pending.

TLI (Top Level Hardware Interrupt)

This hardware interrupt occurs when a specific edge is detected on the dedicated TLI pin.

**Caution**: A TRAP instruction must not be used in a TLI service routine.

External Interrupts

External interrupts allow the processor to exit from HALT low power mode.

External interrupt sensitivity is software selectable through the External Interrupt Control register (EICR).

External interrupt triggered on edge will be latched and the interrupt request automatically cleared upon entering the interrupt service routine.

If several input pins of a group connected to the same interrupt line are selected simultaneously, these will be logically ORed.

Peripheral Interrupts

Usually the peripheral interrupts cause the MCU to exit from HALT mode except those mentioned in the "Interrupt Mapping" table.

A peripheral interrupt occurs when a specific flag is set in the peripheral status registers and if the corresponding enable bit is set in the peripheral control register.

The general sequence for clearing an interrupt is based on an access to the status register followed by a read or write to an associated register.

**Note**: The clearing sequence resets the internal latch. A pending interrupt (that is, waiting for being serviced) will therefore be lost if the clear sequence is executed.

30/224

## 7.3 INTERRUPTS AND LOW POWER MODES

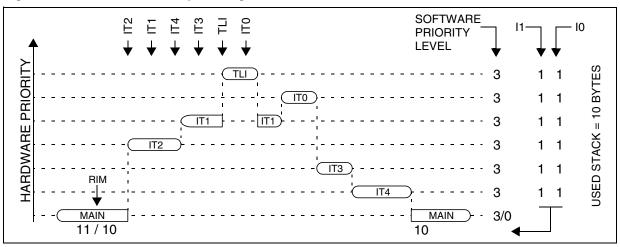

All interrupts allow the processor to exit the WAIT low power mode. On the contrary, only external and other specified interrupts allow the processor to exit from the HALT modes (see column "Exit from HALT" in "Interrupt Mapping" table). When several pending interrupts are present while exiting HALT mode, the first one serviced can only be an interrupt with exit from HALT mode capability and it is selected through the same decision process shown in Figure 2.

**Note:** If an interrupt, that is not able to Exit from HALT mode, is pending with the highest priority when exiting HALT mode, this interrupt is serviced after the first one serviced.

## 7.4 CONCURRENT & NESTED MANAGEMENT

The following Figure 3 and Figure 4 show two different interrupt management modes. The first is called concurrent mode and does not allow an interrupt to be interrupted, unlike the nested mode in Figure 4. The interrupt hardware priority is given in this order from the lowest to the highest: MAIN, IT4, IT3, IT2, IT1, IT0, TLI. The software priority is given for each interrupt.

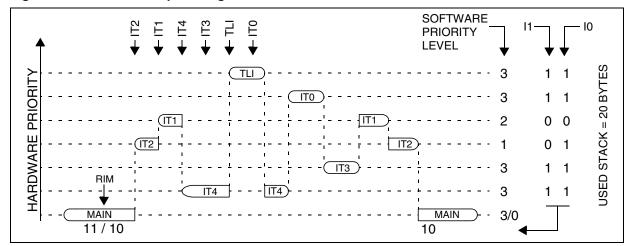

**Warning**: A stack overflow may occur without notifying the software of the failure.

#### Figure 19. Concurrent Interrupt Management

Figure 20. Nested Interrupt Management

57

#### 7.5 INTERRUPT REGISTER DESCRIPTION

#### **CPU CC REGISTER INTERRUPT BITS**

Read/Write

Reset Value: 111x 1010 (xAh)

7							0
1	1	11	н	10	Ν	Z	С

Bit 5, 3 = 11, 10 Software Interrupt Priority

These two bits indicate the current interrupt software priority.

Interrupt Software Priority	Level	l1	10
Level 0 (main)	Low	1	0
Level 1		0	1
Level 2	▼	0	0
Level 3 (= interrupt disable*)	High	1	1

These two bits are set/cleared by hardware when entering in interrupt. The loaded value is given by the corresponding bits in the interrupt software priority registers (ISPRx).

They can be also set/cleared by software with the RIM, SIM, HALT, WFI, IRET and PUSH/POP instructions (see "Interrupt Dedicated Instruction Set" table).

\*Note: TLI, TRAP and RESET events can interrupt a level 3 program.

#### INTERRUPT SOFTWARE PRIORITY REGIS-TERS (ISPRX)

Read/Write (bit 7:4 of **ISPR3** are read only) Reset Value: 1111 1111 (FFh)

	7							0
ISPR0	l1_3	10_3	11_2	10_2	11_1	10_1	l1_0	10_0
ISPR1	11_7	10_7	l1_6	I0_6	l1_5	10_5	11_4	10_4
ISPR2	11_11	10_11	11_10	10_10	l1_9	10_9	l1_8	10_8
ISPR3	1	1	1	1	11_13	10_13	11_12	10_12

These four registers contain the interrupt software priority of each interrupt vector.

 Each interrupt vector (except RESET and TRAP) has corresponding bits in these registers where its own software priority is stored. This correspondence is shown in the following table.

Vector address	ISPRx bits
FFFBh-FFFAh	I1_0 and I0_0 bits*
FFF9h-FFF8h	I1_1 and I0_1 bits
FFE1h-FFE0h	I1_13 and I0_13 bits

Each I1\_x and I0\_x bit value in the ISPRx registers has the same meaning as the I1 and I0 bits in the CC register.

 Level 0 cannot be written (l1\_x = 1, l0\_x = 0). In this case, the previously stored value is kept (Example: previous = CFh, write = 64h, result = 44h)

The RESET, TRAP and TLI vectors have no software priorities. When one is serviced, the I1 and I0 bits of the CC register are both set.

\*Note: Bits in the ISPRx registers which correspond to the TLI can be read and written but they are not significant in the interrupt process management.

**Caution**: If the I1\_x and I0\_x bits are modified while the interrupt x is executed the following behavior has to be considered: If the interrupt x is still pending (new interrupt or flag not cleared) and the new software priority is higher than the previous one, the interrupt x is re-entered. Otherwise, the software priority stays unchanged up to the next interrupt request (after the IRET of the interrupt x).

57

Instruction	New Description	Function/Example	11	Н	10	Ν	Z	С
HALT	Entering Halt mode		1		0			
IRET	Interrupt routine return	Pop CC, A, X, PC	11	Н	10	Ν	Z	С
JRM	Jump if I1:0 = 11 (level 3)	11:0 = 11 ?						
JRNM	Jump if I1:0 <> 11	1:0 <> 11 ?						
POP CC	Pop CC from the Stack	Mem => CC	11	Н	10	Ν	Z	С
RIM	Enable interrupt (level 0 set)	Load 10 in I1:0 of CC	1		0			
SIM	Disable interrupt (level 3 set)	Load 11 in I1:0 of CC	1		1			
TRAP	Software trap	Software NMI	1		1			
WFI	Wait for interrupt		1		0			

# Table 7. Dedicated Interrupt Instruction Set

Note: During the execution of an interrupt routine, the HALT, POPCC, RIM, SIM and WFI instructions change the current software priority up to the next IRET instruction or one of the previously mentioned instructions.

## **Table 8. Interrupt Mapping**

N°	Source Block	Description Registe Label		Priority Order	Exit from HALT <sup>1)</sup>	Address Vector
	RESET	Reset	N/A		yes	FFFEh-FFFFh
	TRAP	Software interrupt	IN/A		no	FFFCh-FFFDh
0	TLI	External top level interrupt	EICR	Highest	yes	FFFAh-FFFBh
1	MCC/RTC	Main clock controller time base interrupt	MCCSR	Priority	yes	FFF8h-FFF9h
2	ei0/AWUFH	External interrupt ei0/ Auto wake-up from Halt	EICR/ AWUCSR			FFF6h-FFF7h
3	ei1/AVD	External interrupt ei1/Auxiliary Voltage Detector			yes <sup>2)</sup>	FFF4h-FFF5h
4	ei2	External interrupt ei2	EICR			FFF2h-FFF3h
5	ei3	External interrupt ei3	EICR			FFF0h-FFF1h
6		not used				FFEEh-FFEFh
7		not used				FFECh-FFEDh
8	SPI	SPI peripheral interrupts	SPICSR		yes	FFEAh-FFEBh
9	TIMER8	8-bit TIMER peripheral interrupts	T8_TCR1		no	FFE8h-FFE9h
10	TIMER16	16-bit TIMER peripheral interrupts	TCR1		no	FFE6h-FFE7h
11	LINSCI2	LINSCI2 Peripheral interrupts	SCI2CR1		no	FFE4h-FFE5h
12	LINSCI1	LINSCI1 LINSCI1 Peripheral interrupts (LIN Master/ Slave) SCI1CR1			no <sup>3)</sup>	FFE2h-FFE3h
13	PWM ART	8-bit PWM ART interrupts	PWMCR	Priority	yes	FFE0h-FFE1h

#### Notes:

1. Valid for HALT and ACTIVE HALT modes except for the MCC/RTC interrupt source which exits from ACTIVE HALT mode only.

2. Except AVD interrupt

3. It is possible to exit from Halt using the external interrupt which is mapped on the RDI pin.

# 7.6 EXTERNAL INTERRUPTS

# 7.6.1 I/O Port Interrupt Sensitivity

The external interrupt sensitivity is controlled by the ISxx bits in the EICR register (Figure 21). This control allows up to four fully independent external interrupt source sensitivities.

Each external interrupt source can be generated on four (or five) different events on the pin:

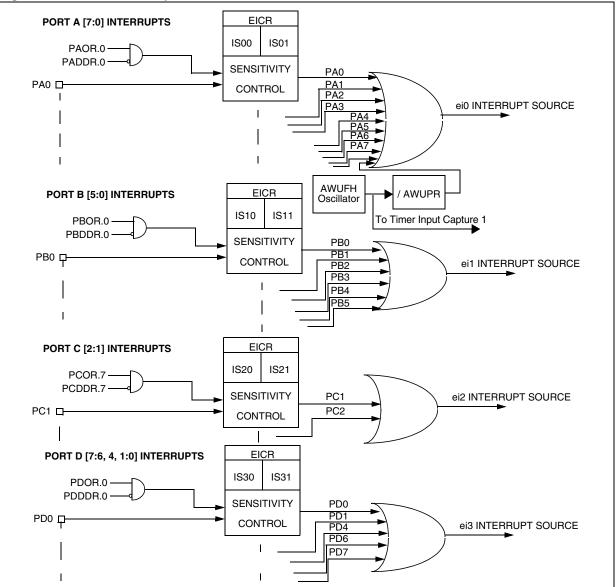

- Falling edge
- Rising edge

#### Figure 21. External Interrupt Control Bits

- Falling and rising edge
- Falling edge and low level

To guarantee correct functionality, the sensitivity bits in the EICR register can be modified only when the I1 and I0 bits of the CC register are both set to 1 (level 3). This means that interrupts must be disabled before changing sensitivity.

The pending interrupts are cleared by writing a different value in the ISx[1:0] of the EICR.

#### 7.6.2 Register Description EXTERNAL INTERRUPT CONTROL REGISTER 0 (EICR0) Read/Write

Reset Value: 0000 0000 (00h)

7							0	
IS31	IS30	IS21	IS20	IS11	IS10	IS01	IS00	

# Bits 7:6 = **IS3[1:0]** *ei3 sensitivity*

The interrupt sensitivity, defined using the IS3[1:0] bits, is applied to the ei3 external interrupts:

IS31	IS30	External Interrupt Sensitivity			
0	0	Falling edge & low level			
0	1	Rising edge only			
1	0	Falling edge only			
1	1	Rising and falling edge			

These 2 bits can be written only when I1 and I0 of the CC register are both set to 1 (level 3).

### Bits 5:4 = IS2[1:0] ei2 sensitivity

The interrupt sensitivity, defined using the IS2[1:0] bits, is applied to the ei2 external interrupts:

IS21	IS20	External Interrupt Sensitivity				
0	0	Falling edge & low level				
0	1	Rising edge only				
1	0	Falling edge only				
1	1	Rising and falling edge				

These 2 bits can be written only when I1 and I0 of the CC register are both set to 1 (level 3).

#### Bits 3:2 = IS1[1:0] ei1 sensitivity

The interrupt sensitivity, defined using the IS1[1:0] bits, is applied to the ei1 external interrupts:

IS11	IS10	External Interrupt Sensitivity				
0	0	Falling edge & low level				
0	1	Rising edge only				
1	0	Falling edge only				
1	1	Rising and falling edge				

These 2 bits can be written only when I1 and I0 of the CC register are both set to 1 (level 3).

#### Bits 1:0 = **ISO[1:0]** ei0 sensitivity

The interrupt sensitivity, defined using the ISO[1:0] bits, is applied to the ei0 external interrupts:

IS01	IS00	External Interrupt Sensitivity
0	0	Falling edge & low level
0	1	Rising edge only
1	0	Falling edge only
1	1	Rising and falling edge

These 2 bits can be written only when I1 and I0 of the CC register are both set to 1 (level 3).

# EXTERNAL INTERUPT CONTROL REGISTER 1 (EICR1)

Read/Write

Reset Value: 0000 0000 (00h)

7							0
0	0	0	0	0	0	TLIS	TLIE

Blts 7:2 = Reserved

# Bit 1 = **TLIS** *Top Level Interrupt sensitivity*

This bit configures the TLI edge sensitivity. It can be set and cleared by software only when TLIE bit is cleared.

0: Falling edge

1: Rising edge

#### Bit 0 = **TLIE** *Top Level Interrupt enable*

This bit allows to enable or disable the TLI capability on the dedicated pin. It is set and cleared by software.

0: TLI disabled

1: TLI enabled

# Notes:

- A parasitic interrupt can be generated when clearing the TLIE bit.
- In some packages, the TLI pin is not available. In this case, the TLIE bit must be kept low to avoid parasitic TLI interrupts.

# **8 POWER SAVING MODES**

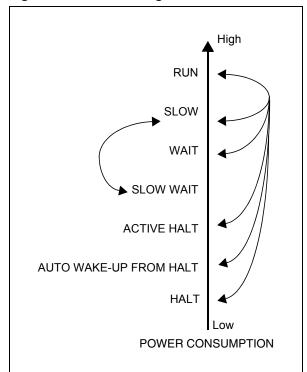

# **8.1 INTRODUCTION**

To give a large measure of flexibility to the application in terms of power consumption, five main power saving modes are implemented in the ST7 (see Figure 1.):

- Slow
- Wait (and Slow-Wait)
- Active Halt
- Auto Wake-up From Halt (AWUFH)
- Halt

After a RESET the normal operating mode is selected by default (RUN mode). This mode drives the device (CPU and embedded peripherals) by means of a master clock which is based on the main oscillator frequency divided or multiplied by 2 ( $f_{OSC2}$ ).

From RUN mode, the different power saving modes may be selected by setting the relevant register bits or by calling the specific ST7 software instruction whose action depends on the oscillator status.

#### Figure 22. Power Saving Mode Transitions

# 8.2 SLOW MODE

This mode has two targets:

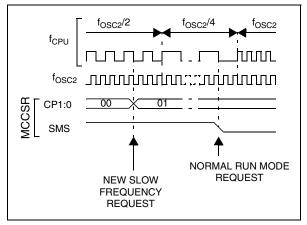

- To reduce power consumption by decreasing the internal clock in the device,
- To adapt the internal clock frequency (f<sub>CPU</sub>) to the available supply voltage.

SLOW mode is controlled by three bits in the MCCSR register: the SMS bit which enables or disables Slow mode and two CPx bits which select the internal slow frequency (f<sub>CPU</sub>).

In this mode, the master clock frequency ( $f_{OSC2}$ ) can be divided by 2, 4, 8 or 16. The CPU and peripherals are clocked at this lower frequency ( $f_{CPU}$ ).

**Note**: SLOW-WAIT mode is activated by entering WAIT mode while the device is in SLOW mode.

#### Figure 23. SLOW Mode Clock Transitions

# 8.3 WAIT MODE

WAIT mode places the MCU in a low power consumption mode by stopping the CPU.

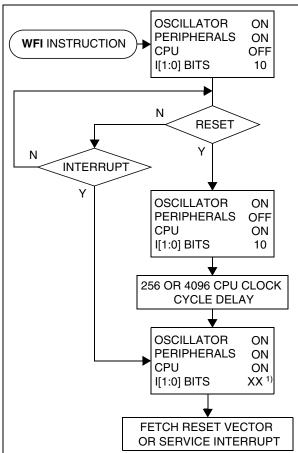

This power saving mode is selected by calling the 'WFI' instruction.

All peripherals remain active. During WAIT mode, the I[1:0] bits of the CC register are forced to '10', to enable all interrupts. All other registers and memory remain unchanged. The MCU remains in WAIT mode until an interrupt or RESET occurs, whereupon the Program Counter branches to the starting address of the interrupt or Reset service routine.

The MCU will remain in WAIT mode until a Reset or an Interrupt occurs, causing it to wake up.

Refer to Figure 3.

57

#### Figure 24. WAIT Mode Flow-chart

#### Note:

**1.** Before servicing an interrupt, the CC register is pushed on the stack. The I[1:0] bits of the CC register are set to the current software priority level of the interrupt routine and recovered when the CC register is popped.

#### 8.4 HALT MODE

The HALT mode is the lowest power consumption mode of the MCU. It is entered by executing the 'HALT' instruction when the OIE bit of the Main Clock Controller Status register (MCCSR) is cleared (see section 10.2 on page 59 for more details on the MCCSR register) and when the AWUEN bit in the AWUCSR register is cleared.

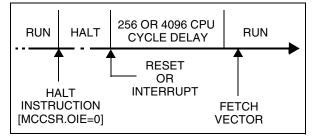

The MCU can exit HALT mode on reception of either a specific interrupt (see Table 8, "Interrupt Mapping," on page 34) or a RESET. When exiting HALT mode by means of a RESET or an interrupt, the oscillator is immediately turned on and the 256 or 4096 CPU cycle delay is used to stabilize the oscillator. After the start up delay, the CPU resumes operation by servicing the interrupt or by fetching the reset vector which woke it up (see Figure 5.).

When entering HALT mode, the I[1:0] bits in the CC register are forced to '10b' to enable interrupts. Therefore, if an interrupt is pending, the MCU wakes up immediately.

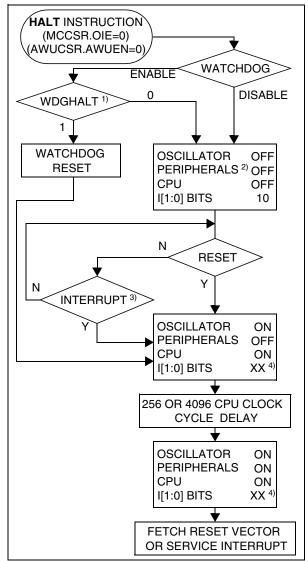

In HALT mode, the main oscillator is turned off causing all internal processing to be stopped, including the operation of the on-chip peripherals. All peripherals are not clocked except the ones which get their clock supply from another clock generator (such as an external or auxiliary oscillator).

The compatibility of Watchdog operation with HALT mode is configured by the "WDGHALT" option bit of the option byte. The HALT instruction when executed while the Watchdog system is enabled, can generate a Watchdog RESET (see section 14.1 on page 210 for more details).

#### Figure 25. HALT Timing Overview

#### Notes:

**1.** WDGHALT is an option bit. See option byte section for more details.

**2.** Peripheral clocked with an external clock source can still be active.

**3.** Only some specific interrupts can exit the MCU from HALT mode (such as external interrupt). Refer to Table 8, "Interrupt Mapping," on page 34 for more details.

**4.** Before servicing an interrupt, the CC register is pushed on the stack. The I[1:0] bits of the CC register are set to the current software priority level of the interrupt routine and recovered when the CC register is popped.

#### Halt Mode Recommendations

- Make sure that an external event is available to wake up the microcontroller from Halt mode.
- When using an external interrupt to wake up the microcontroller, reinitialize the corresponding I/O as "Input Pull-up with Interrupt" before executing the HALT instruction. The main reason for this is that the I/O may be wrongly configured due to external interference or by an unforeseen logical condition.
- For the same reason, reinitialize the level sensitiveness of each external interrupt as a precautionary measure.
- The opcode for the HALT instruction is 0x8E. To avoid an unexpected HALT instruction due to a program counter failure, it is advised to clear all occurrences of the data value 0x8E from memory. For example, avoid defining a constant in ROM with the value 0x8E.
- As the HALT instruction clears the interrupt mask in the CC register to allow interrupts, the user may choose to clear all pending interrupt bits before executing the HALT instruction. This avoids entering other peripheral interrupt routines after executing the external interrupt routine corresponding to the wake-up event (reset or external interrupt).

#### **8.5 ACTIVE HALT MODE**

ACTIVE HALT mode is the lowest power consumption mode of the MCU with a real time clock available. It is entered by executing the 'HALT' instruction when MCC/RTC interrupt enable flag (OIE bit in MCCSR register) is set and when the AWUEN bit in the AWUCSR register is cleared (See "Register Description" on page 9.)

MCCSR OIE bit	Power Saving Mode entered when HALT instruction is executed
0	HALT mode
1	ACTIVE HALT mode

The MCU can exit ACTIVE HALT mode on reception of the RTC interrupt and some specific interrupts (see Table 8, "Interrupt Mapping," on page 34) or a RESET. When exiting ACTIVE HALT mode by means of a RESET a 4096 or 256 CPU cycle delay occurs (depending on the option byte). After the start up delay, the CPU resumes operation by servicing the interrupt or by fetching the reset vector which woke it up (see Figure 7.).

When entering ACTIVE HALT mode, the I[1:0] bits in the CC register are are forced to '10b' to enable interrupts. Therefore, if an interrupt is pending, the MCU wakes up immediately.

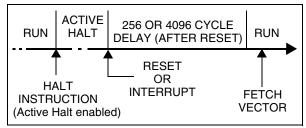

In ACTIVE HALT mode, only the main oscillator and its associated counter (MCC/RTC) are running to keep a wake-up time base. All other peripherals are not clocked except those which get their clock supply from another clock generator (such as external or auxiliary oscillator).

The safeguard against staying locked in ACTIVE HALT mode is provided by the oscillator interrupt.

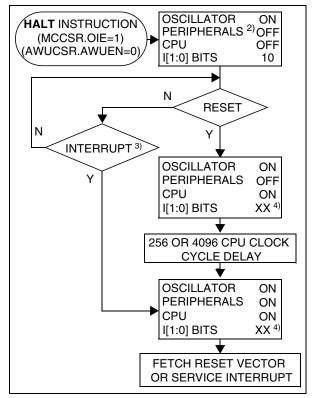

**Note:** As soon as active halt is enabled, executing a HALT instruction while the Watchdog is active does not generate a RESET.

This means that the device cannot spend more than a defined delay in this power saving mode.

# Figure 27. ACTIVE HALT Timing Overview

# Figure 28. ACTIVE HALT Mode Flow-chart

#### Notes:

- 1. This delay occurs only if the MCU exits ACTIVE HALT mode by means of a RESET.
- 2. Peripheral clocked with an external clock source can still be active.
- 3. Only the RTC interrupt and some specific interrupts can exit the MCU from ACTIVE HALT mode (such as external interrupt). Refer to Table 8, "Interrupt Mapping," on page 34 for more details.
- 4. Before servicing an interrupt, the CC register is pushed on the stack. The I[1:0] bits in the CC register are set to the current software priority level of the interrupt routine and restored when the CC register is popped.

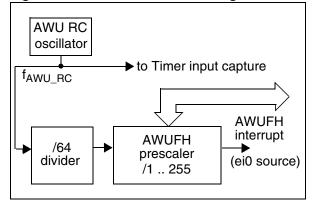

# 8.6 AUTO WAKE-UP FROM HALT MODE

Auto Wake-Up From Halt (AWUFH) mode is similar to Halt mode with the addition of an internal RC oscillator for wake-up. Compared to ACTIVE HALT mode, AWUFH has lower power consumption because the main clock is not kept running, but there is no accurate realtime clock available.

It is entered by executing the HALT instruction when the AWUEN bit in the AWUCSR register has been set and the OIE bit in the MCCSR register is cleared (see section 10.2 on page 59 for more details).

#### Figure 29. AWUFH Mode Block Diagram

As soon as HALT mode is entered, and if the AWUEN bit has been set in the AWUCSR register, the AWU RC oscillator provides a clock signal ( $f_{AWU}_{RC}$ ). Its frequency is divided by a fixed divider and a programmable prescaler controlled by the AWUPR register. The output of this prescaler provides the delay time. When the delay has elapsed the AWUF flag is set by hardware and an interrupt wakes up the MCU from Halt mode. At the same time the main oscillator is immediately turned on

#### Figure 30. AWUF Halt Timing Diagram

and a 256 or 4096 cycle delay is used to stabilize it. After this start-up delay, the CPU resumes operation by servicing the AWUFH interrupt. The AWU flag and its associated interrupt are cleared by software reading the AWUCSR register.

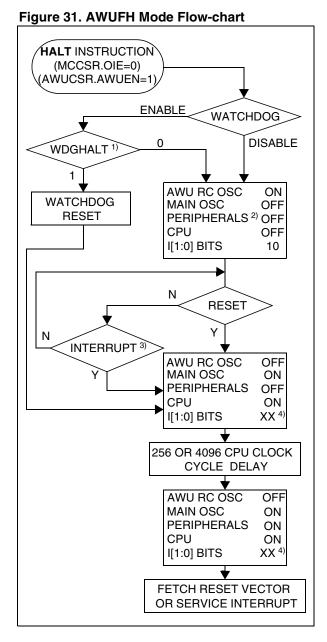

To compensate for any frequency dispersion of the AWU RC oscillator, it can be calibrated by measuring the clock frequency  $f_{AWU}$  RC and then calculating the right prescaler value. Measurement mode is enabled by setting the AWUM bit in the AWUCSR register in Run mode. This connects  $f_{AWU}$  RC to the ICAP1 input of the 16-bit timer, allowing the  $f_{AWU}$  RC to be measured using the main oscillator clock as a reference timebase.

#### Similarities with Halt mode

The following AWUFH mode behavior is the same as normal Halt mode:

- The MCU can exit AWUFH mode by means of any interrupt with exit from Halt capability or a reset (see Section 1.4 HALT MODE).
- When entering AWUFH mode, the I[1:0] bits in the CC register are forced to 10b to enable interrupts. Therefore, if an interrupt is pending, the MCU wakes up immediately.
- In AWUFH mode, the main oscillator is turned off causing all internal processing to be stopped, including the operation of the on-chip peripherals. None of the peripherals are clocked except those which get their clock supply from another clock generator (such as an external or auxiliary oscillator like the AWU oscillator).
- The compatibility of Watchdog operation with AWUFH mode is configured by the WDGHALT option bit in the option byte. Depending on this setting, the HALT instruction when executed while the Watchdog system is enabled, can generate a Watchdog RESET.

		<b>↓</b> t <sub>AWU</sub>	<b></b>		
	RUN MODE	HALT MODE		256 or 4096 t <sub>CPU</sub>	RUN MODE
f <sub>CPU</sub>			[]		
f <sub>AWU_R</sub>	c			1	Clear by,software
AWUFH	l interrupt				•

# Notes:

**1.** WDGHALT is an option bit. See option byte section for more details.

**2.** Peripheral clocked with an external clock source can still be active.

**3.** Only an AWUFH interrupt and some specific interrupts can exit the MCU from HALT mode (such as external interrupt). Refer to Table 8, "Interrupt Mapping," on page 34 for more details.

**4.** Before servicing an interrupt, the CC register is pushed on the stack. The I[1:0] bits of the CC register are set to the current software priority level of the interrupt routine and recovered when the CC register is popped.

Δy/

#### 8.6.1 Register Description

#### AWUFH CONTROL/STATUS REGISTER (AWUCSR)

Read/Write (except bit 2 read only) Reset Value: 0000 0000 (00h)

7							0
0	0	0	0	0	AWU F	AWU M	AWU EN

Bits 7:3 = Reserved.

#### Bit 2 = AWUF Auto Wake-Up Flag

This bit is set by hardware when the AWU module generates an interrupt and cleared by software on reading AWUCSR.

0: No AWU interrupt occurred

1: AWU interrupt occurred

#### Bit 1 = AWUM Auto Wake-Up Measurement

This bit enables the AWU RC oscillator and connects its output to the ICAP1 input of the 16-bit timer. This allows the timer to be used to measure the AWU RC oscillator dispersion and then compensate this dispersion by providing the right value in the AWUPR register.

0: Measurement disabled

1: Measurement enabled

Bit 0 = **AWUEN** Auto Wake-Up From Halt Enabled This bit enables the Auto Wake-Up From Halt feature: once HALT mode is entered, the AWUFH wakes up the microcontroller after a time delay defined by the AWU prescaler value. It is set and cleared by software.

Table 10. AWU Register Map and Reset Values

- 0: AWUFH (Auto Wake-Up From Halt) mode disabled
- 1: AWUFH (Auto Wake-Up From Halt) mode enabled

#### AWUFH PRESCALER REGISTER (AWUPR) Read/Write

Reset Value: 1111 1111 (FFh)

7							0	
AWU PR7	AWU PR6	AWU PR5	AWU PR4	AWU PR3	AWU PR2	AWU PR1	AWU PR0	

Bits 7:0 = **AWUPR[7:0]** Auto Wake-Up Prescaler These 8 bits define the AWUPR Dividing factor (as explained below:

AWUPR[7:0]	Dividing factor		
00h	Forbidden (See note)		
01h	1		
FEh	254		
FFh	255		

In AWU mode, the period that the MCU stays in Halt Mode ( $t_{AWU}$  in Figure 9.) is defined by

$$^{t}AWU = 64 \times AWUPR \times \frac{1}{f_{AWURC}} + ^{t}RCSTRT$$

This prescaler register can be programmed to modify the time that the MCU stays in Halt mode before waking up automatically.

**Note:** If 00h is written to AWUPR, depending on the product, an interrupt is generated immediately after a HALT instruction or the AWUPR remains unchanged.

Address (Hex.)	Register Label	7	6	5	4	3	2	1	0

# 9 I/O PORTS

# 9.1 INTRODUCTION

The I/O ports offer different functional modes: – transfer of data through digital inputs and outputs

- and for specific pins:
- external interrupt generation
- alternate signal input/output for the on-chip peripherals.

An I/O port contains up to 8 pins. Each pin can be programmed independently as digital input (with or without interrupt generation) or digital output.

#### 9.2 FUNCTIONAL DESCRIPTION

Each port has two main registers:

- Data Register (DR)
- Data Direction Register (DDR)
- and one optional register:
- Option Register (OR)

Each I/O pin may be programmed using the corresponding register bits in the DDR and OR registers: Bit X corresponding to pin X of the port. The same correspondence is used for the DR register.

The following description takes into account the OR register, (for specific ports which do not provide this register refer to the I/O Port Implementation section). The generic I/O block diagram is shown in Figure 1

#### 9.2.1 Input Modes

The input configuration is selected by clearing the corresponding DDR register bit.

In this case, reading the DR register returns the digital value applied to the external I/O pin.

Different input modes can be selected by software through the OR register.

#### Notes:

1. Writing the DR register modifies the latch value but does not affect the pin status.

2. When switching from input to output mode, the DR register has to be written first to drive the correct level on the pin as soon as the port is configured as an output.

3. Do not use read/modify/write instructions (BSET or BRES) to modify the DR register as this might corrupt the DR content for I/Os configured as input.

#### External interrupt function

When an I/O is configured as Input with Interrupt, an event on this I/O can generate an external interrupt request to the CPU. Each pin can independently generate an interrupt request. The interrupt sensitivity is independently programmable using the sensitivity bits in the EICR register.

Each external interrupt vector is linked to a dedicated group of I/O port pins (see pinout description and interrupt section). If several input pins are selected simultaneously as interrupt sources, these are first detected according to the sensitivity bits in the EICR register and then logically ORed.

The external interrupts are hardware interrupts, which means that the request latch (not accessible directly by the application) is automatically cleared when the corresponding interrupt vector is fetched. To clear an unwanted pending interrupt by software, the sensitivity bits in the EICR register must be modified.

#### 9.2.2 Output Modes

The output configuration is selected by setting the corresponding DDR register bit. In this case, writing the DR register applies this digital value to the I/O pin through the latch. Then reading the DR register returns the previously stored value.

Two different output modes can be selected by software through the OR register: Output push-pull and open-drain.

DR register value and output pin status:

DR	Push-pull	Open-drain
0	V <sub>SS</sub>	Vss
1	V <sub>DD</sub>	Floating

#### 9.2.3 Alternate Functions

When an on-chip peripheral is configured to use a pin, the alternate function is automatically selected. This alternate function takes priority over the standard I/O programming.

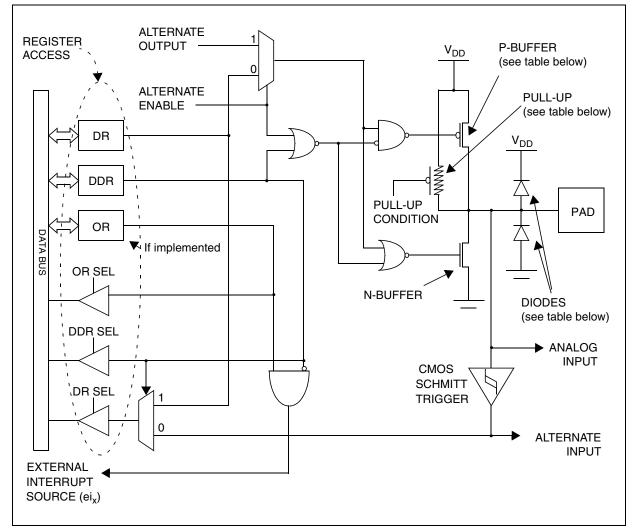

When the signal is coming from an on-chip peripheral, the I/O pin is automatically configured in output mode (push-pull or open drain according to the peripheral).

When the signal is going to an on-chip peripheral, the I/O pin must be configured in input mode. In this case, the pin state is also digitally readable by addressing the DR register.

**Note**: Input pull-up configuration can cause unexpected value at the input of the alternate peripheral input. When an on-chip peripheral use a pin as input and output, this pin has to be configured in input floating mode.

# Table 11. I/O Port Mode Options

Configuration Mode		Dull Up	Pull-Up P-Buffer		des
		Pull-Op	F-Duilei	to V <sub>DD</sub>	to V <sub>SS</sub>
Input	Floating with/without Interrupt	Off	Off		On
Input	Pull-up with/without Interrupt	On		On	
	Push-pull	Off	On	On	
Output	Open Drain (logic level)		Off		
	True Open Drain	NI	NI	NI (see note)	

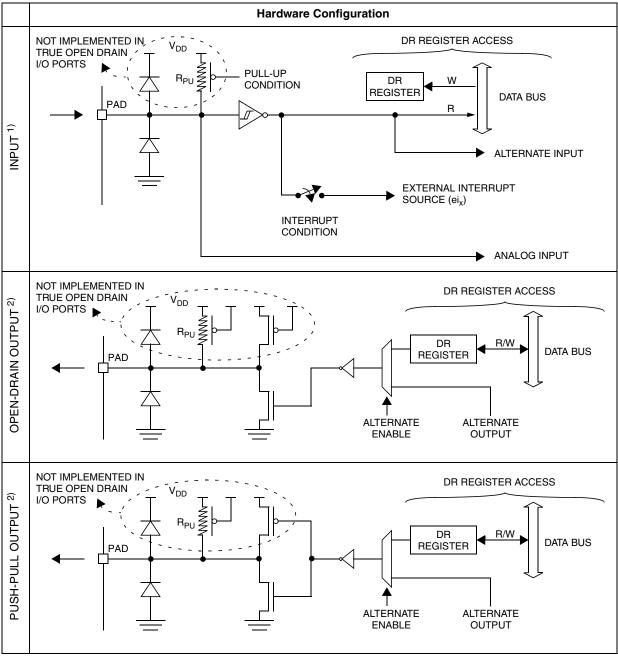

Legend: NI - not implemented

Off - implemented not activated

On - implemented and activated

**Note**: The diode to  $V_{DD}$  is not implemented in the true open drain pads. A local protection between the pad and  $V_{SS}$  is implemented to protect the device against positive stress.

#### Notes:

- 1. When the I/O port is in input configuration and the associated alternate function is enabled as an output, reading the DR register will read the alternate function output status.
- When the I/O port is in output configuration and the associated alternate function is enabled as an input, the alternate function reads the pin status given by the DR register content.

**CAUTION**: The alternate function must not be activated as long as the pin is configured as input with interrupt, in order to avoid generating spurious interrupts.

#### Analog alternate function

When the pin is used as an ADC input, the I/O must be configured as floating input. The analog multiplexer (controlled by the ADC registers) switches the analog voltage present on the selected pin to the common analog rail which is connected to the ADC input.

It is recommended not to change the voltage level or loading on any port pin while conversion is in progress. Furthermore it is recommended not to have clocking pins located close to a selected analog pin.

**WARNING**: The analog input voltage level must be within the limits stated in the absolute maximum ratings.

# 9.3 I/O PORT IMPLEMENTATION

5/

The hardware implementation on each I/O port depends on the settings in the DDR and OR registers and specific feature of the I/O port such as ADC Input or true open drain.

Switching these I/O ports from one state to another should be done in a sequence that prevents unwanted side effects. Recommended safe transitions are illustrated in Figure 2 on page 4. Other transitions are potentially risky and should be avoided, since they are likely to present unwanted side-effects such as spurious interrupt generation.

# Figure 33. Interrupt I/O Port State Transitions

	▶ 00 ◀	→ 10 ←	▶ 11					
INPUT floating/pull-up interrupt	INPUT floating (reset state)	OUTPUT open-drain	OUTPUT push-pull					
(1000000000) $(XX) = DDR, OR$								

#### 9.4 LOW POWER MODES

Mode	Description
WAIT	No effect on I/O ports. External interrupts cause the device to exit from WAIT mode.
HALT	No effect on I/O ports. External interrupts cause the device to exit from HALT mode.

#### 9.5 INTERRUPTS

The external interrupt event generates an interrupt if the corresponding configuration is selected with DDR and OR registers and the interrupt mask in the CC register is not active (RIM instruction).

Interrupt Event	Event Flag	Enable Control Bit	Exit from Wait	Exit from Halt
External interrupt on selected external event	-	DDRx ORx	Yes	

# 9.6 I/O PORT REGISTER CONFIGURATIONS

The I/O port register configurations are summarized as follows.

#### 9.6.1 Standard Ports

PB7:6, PC0, PC3, PC7:5, PD3:2, PD5, PE7:0, PF7:0

MODE	DDR	OR
floating input	0	0
pull-up input	0	1
open drain output	1	0
push-pull output	1	1

# 9.6.2 Interrupt Ports

#### PA0,2,4,6; PB0,2,4; PC1; PD0,6

(with pull-up)

MODE	DDR	OR
floating input	0	0
pull-up interrupt input	0	1
open drain output	1	0
push-pull output	1	1

# PA1,3,5,7; PB1,3,5; PC2; PD1,4,7

(without pull-up)

MODE	DDR	OR
floating input	0	0
floating interrupt input	0	1
open drain output	1	0
push-pull output	1	1

#### 9.6.3 Pull-up Input Port PC4

MODE					
pull-up input					

The PC4 port cannot operate as a general purpose output. If DDR = 1 it is still possible to read the port through the DR register.

57

# **10 ON-CHIP PERIPHERALS**

# **10.1 WINDOW WATCHDOG (WWDG)**

# 10.1.1 Introduction

The Window Watchdog is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence. The Watchdog circuit generates an MCU reset on expiry of a programmed time period, unless the program refreshes the contents of the downcounter before the T6 bit becomes cleared. An MCU reset is also generated if the 7-bit downcounter value (in the control register) is refreshed before the downcounter has reached the window register value. This implies that the counter must be refreshed in a limited window.

#### 10.1.2 Main Features

- Programmable free-running downcounter
- Conditional reset

47/

- Reset (if watchdog activated) when the downcounter value becomes less than 40h
- Reset (if watchdog activated) if the down-

# Figure 34. Watchdog Block Diagram

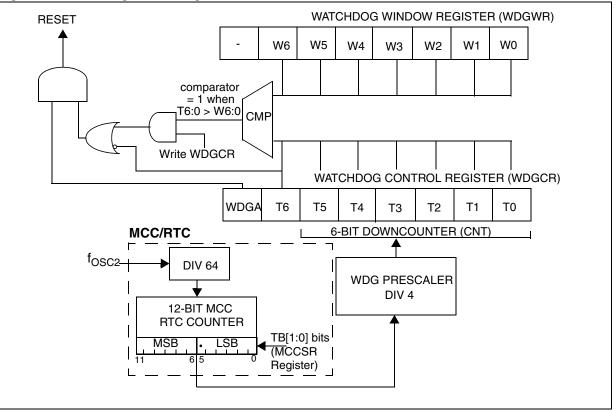

counter is reloaded outside the window (see Figure 4)

- Hardware/Software Watchdog activation (selectable by option byte)
- Optional reset on HALT instruction (configurable by option byte)

#### **10.1.3 Functional Description**

The counter value stored in the WDGCR register (bits T[6:0]), is decremented every 16384  $f_{OSC2}$  cycles (approx.), and the length of the timeout period can be programmed by the user in 64 increments.

If the watchdog is activated (the WDGA bit is set) and when the 7-bit downcounter (T[6:0] bits) rolls over from 40h to 3Fh (T6 becomes cleared), it initiates a reset cycle pulling low the reset pin for typically  $30\mu$ s. If the software reloads the counter while the counter is greater than the value stored in the window register, then a reset is generated.

The application program must write in the WDGCR register at regular intervals during normal operation to prevent an MCU reset. This operation must occur only when the counter value is lower than the window register value. The value to be stored in the WDGCR register must be between FFh and C0h (see Figure 2):

- Enabling the watchdog:

When Software Watchdog is selected (by option byte), the watchdog is disabled after a reset. It is enabled by setting the WDGA bit in the WDGCR register, then it cannot be disabled again except by a reset.

When Hardware Watchdog is selected (by option byte), the watchdog is always active and the WDGA bit is not used.

- Controlling the downcounter:

This downcounter is free-running: It counts down even if the watchdog is disabled. When the watchdog is enabled, the T6 bit must be set to prevent generating an immediate reset. The T[5:0] bits contain the number of increments which represents the time delay before the watchdog produces a reset (see Figure 2. Approximate Timeout Duration). The timing varies between a minimum and a maximum value due to the unknown status of the prescaler when writing to the WDGCR register (see Figure 3).

The window register (WDGWR) contains the high limit of the window: To prevent a reset, the downcounter must be reloaded when its value is lower than the window register value and greater than 3Fh. Figure 4 describes the window watch-dog process.

**Note:** The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).

Watchdog Reset on Halt option
 If the watchdog is activated and the watchdog reset on halt option is selected, then the HALT instruction will generate a Reset.

#### 10.1.4 Using Halt Mode with the WDG

If Halt mode with Watchdog is enabled by option byte (no watchdog reset on HALT instruction), it is recommended before executing the HALT instruction to refresh the WDG counter, to avoid an unexpected WDG reset immediately after waking up the microcontroller.

47/

**\$7** 

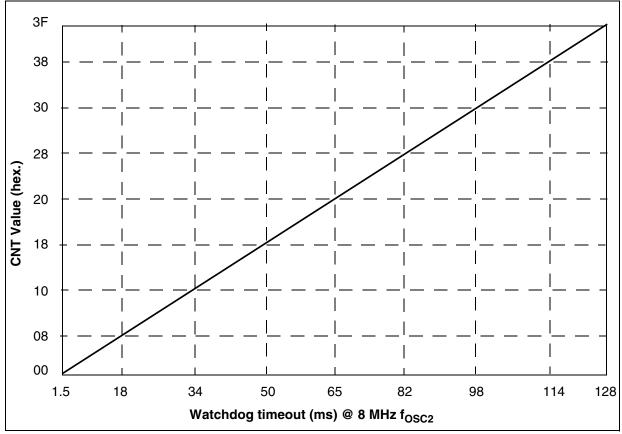

#### 10.1.5 How to Program the Watchdog Timeout

Figure 2 shows the linear relationship between the 6-bit value to be loaded in the Watchdog Counter (CNT) and the resulting timeout duration in milliseconds. This can be used for a quick calculation without taking the timing variations into account. If

Figure 35. Approximate Timeout Duration

more precision is needed, use the formulae in Figure 3.

**Caution:** When writing to the WDGCR register, always write 1 in the T6 bit to avoid generating an immediate reset.

# Figure 36. Exact Timeout Duration (tmin and tmax)

# WHERE:

 $t_{min0} = (LSB + 128) \times 64 \times t_{OSC2}$  $t_{max0} = 16384 \times t_{OSC2}$  $t_{OSC2} = 125$ ns if  $f_{OSC2} = 8$  MHz

CNT = Value of T[5:0] bits in the WDGCR register (6 bits) MSB and LSB are values from the table below depending on the timebase selected by the TB[1:0] bits in the MCCSR register

TB1 Bit (MCCSR Reg.)	TB0 Bit (MCCSR Reg.)	Selected MCCSR Timebase	MSB	LSB
0	0	2ms	4	59
0	1	4ms	8	53
1	0	10ms	20	35
1	1	25ms	49	54

To calculate the minimum Watchdog Timeout (tmin):

**IF** CNT <  $\left[\frac{MSB}{4}\right]$  **THEN**  $t_{min} = t_{min0} + 16384 \times CNT \times t_{osc2}$ 

**ELSE** 
$$t_{min} = t_{min0} + \left[ 16384 \times \left( CNT - \left[ \frac{4CNT}{MSB} \right] \right) + (192 + LSB) \times 64 \times \left[ \frac{4CNT}{MSB} \right] \right] \times t_{osc2}$$

To calculate the maximum Watchdog Timeout (t<sub>max</sub>):

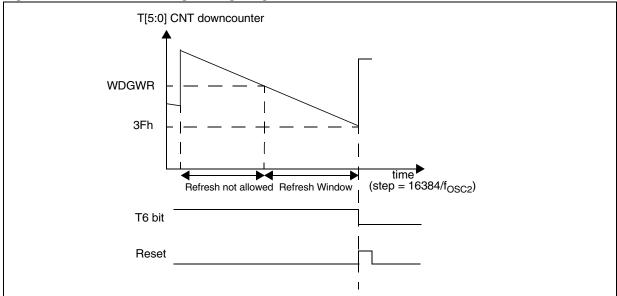

$$\begin{aligned} \textbf{IF} \ \textbf{CNT} \leq \begin{bmatrix} \underline{MSB} \\ 4 \end{bmatrix} & \textbf{THEN} \ t_{max} = t_{max0} + 16384 \times \textbf{CNT} \times t_{osc2} \\ & \textbf{ELSE} \ t_{max} = t_{max0} + \left[ 16384 \times \left( \textbf{CNT} - \left[ \frac{4\textbf{CNT}}{\textbf{MSB}} \right] \right) + (192 + \textbf{LSB}) \times 64 \times \left[ \frac{4\textbf{CNT}}{\textbf{MSB}} \right] \right] \times t_{osc2} \end{aligned}$$

**Note:** In the above formulae, division results must be rounded down to the next integer value. **Example:** 

With 2ms timeout selected in MCCSR register

Value of T[5:0] Bits in WDGCR Register (Hex.)	Min. Watchdog Timeout (ms) <sup>t</sup> <sub>min</sub>	Max. Watchdog Timeout (ms) t <sub>max</sub>		
00	1.496	2.048		
3F	128	128.552		

# 10.1.6 Low Power Modes

Mode	Description							
SLOW	No effect on Watchdog: The downcounter continues to decrement at normal speed.							
WAIT	No effect on Watchdog: The downcounter continues to decrement.							
	OIE bit in MCCSR register	WDGHALT bit in Option Byte						
HALT	0	0	No Watchdog reset is generated. The MCU enters Halt mode. The Watch- dog counter is decremented once and then stops counting and is no longer able to generate a watchdog reset until the MCU receives an external inter- rupt or a reset.					
			If an interrupt is received (refer to interrupt table mapping to see interrupts which can occur in halt mode), the Watchdog restarts counting after 256 or 4096 CPU clocks. If a reset is generated, the Watchdog is disabled (reset state) unless Hardware Watchdog is selected by option byte. For application recommendations see Section 0.1.8 below.					
	0	1	A reset is generated instead of entering halt mode.					
ACTIVE HALT	1	x	No reset is generated. The MCU enters Active Halt mode. The Watchdog counter is not decremented. It stop counting. When the MCU receives an oscillator interrupt or external interrupt, the Watchdog restarts counting immediately. When the MCU receives a reset the Watchdog restarts counting after 256 or 4096 CPU clocks.					

# 10.1.7 Hardware Watchdog Option

57

If Hardware Watchdog is selected by option byte, the watchdog is always active and the WDGA bit in the WDGCR is not used. Refer to the Option Byte description.

# 10.1.8 Using Halt Mode with the WDG (WDGHALT option)

The following recommendation applies if Halt mode is used when the watchdog is enabled.

 Before executing the HALT instruction, refresh the WDG counter, to avoid an unexpected WDG reset immediately after waking up the microcontroller.

#### 10.1.9 Interrupts

None.

# 10.1.10 Register Description CONTROL REGISTER (WDGCR)

Read/Write

Reset Value: 0111 1111 (7Fh)

7							0
WDGA	Т6	T5	T4	Т3	T2	T1	то

Bit 7 = **WDGA** Activation bit.

This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.

0: Watchdog disabled

1: Watchdog enabled

**Note:** This bit is not used if the hardware watchdog option is enabled by option byte.

Bits 6:0 = **T[6:0]** 7-bit counter (MSB to LSB).

These bits contain the value of the watchdog counter. It is decremented every 16384  $f_{OSC2}$  cycles (approx.). A reset is produced when it rolls over from 40h to 3Fh (T6 becomes cleared).

# WINDOW REGISTER (WDGWR)

# Figure 38. Watchdog Timer Register Map and Reset Values

# **10.2 MAIN CLOCK CONTROLLER WITH REAL TIME CLOCK MCC/RTC**

The Main Clock Controller consists of three different functions:

- a programmable CPU clock prescaler
- a clock-out signal to supply external devices
- a real time clock timer with interrupt capability

Each function can be used independently and simultaneously.

#### 10.2.1 Programmable CPU Clock Prescaler

The programmable CPU clock prescaler supplies the clock for the ST7 CPU and its internal peripherals. It manages SLOW power saving mode (See Section 8.2 "SLOW MODE" for more details).

The prescaler selects the  $f_{CPU}$  main clock frequency and is controlled by three bits in the MCCSR register: CP[1:0] and SMS.

57/

#### 10.2.2 Clock-out Capability

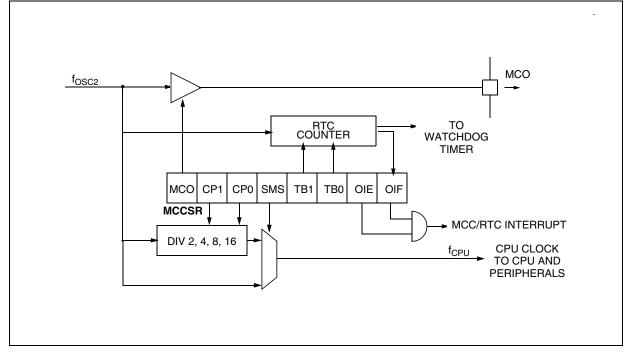

The clock-out capability is an alternate function of an I/O port pin that outputs a  $f_{OSC2}$  clock to drive external devices. It is controlled by the MCO bit in the MCCSR register.

#### 10.2.3 Real Time Clock Timer (RTC)

The counter of the real time clock timer allows an interrupt to be generated based on an accurate real time clock. Four different time bases depending directly on  $f_{OSC2}$  are available. The whole functionality is controlled by 4 bits of the MCCSR register: TB[1:0], OIE and OIF.

When the RTC interrupt is enabled (OIE bit set), the ST7 enters ACTIVE HALT mode when the HALT instruction is executed. See Section 8.5 "ACTIVE HALT MODE" for more details.

# MAIN CLOCK CONTROLLER WITH REAL TIME CLOCK (Cont'd)

# 10.2.4 Low Power Modes

Mode	Description
WAIT	No effect on MCC/RTC peripheral. MCC/RTC interrupt cause the device to exit from WAIT mode.
ACTIVE HALT	No effect on MCC/RTC counter (OIE bit is set), the registers are frozen. MCC/RTC interrupt cause the device to exit from ACTIVE HALT mode.
HALT and AWUF HALT	MCC/RTC counter and registers are fro- zen. MCC/RTC operation resumes when the MCU is woken up by an interrupt with "exit from HALT" capability.

# 10.2.5 Interrupts

The MCC/RTC interrupt event generates an interrupt if the OIE bit of the MCCSR register is set and the interrupt mask in the CC register is not active (RIM instruction).

Interrupt Event	Event Flag	Enable Control Bit	Exit from Wait	Exit from Halt
Time base overflow event	OIF	OIE	Yes	No <sup>1)</sup>

#### Note:

The MCC/RTC interrupt wakes up the MCU from ACTIVE HALT mode, not from HALT or AWUF HALT mode.

# 10.2.6 Register Description MCC CONTROL/STATUS REGISTER (MCCSR)

Read/Write

Reset Value: 0000 0000 (00h)

7

0

мсо	CP1	CP0	SMS	TB1	TB0	OIE	OIF
-----	-----	-----	-----	-----	-----	-----	-----

Bit 7 = **MCO** Main clock out selection

This bit enables the MCO alternate function on the corresponding I/O port. It is set and cleared by software.

- 0: MCO alternate function disabled (I/O pin free for general-purpose I/O)
- 1: MCO alternate function enabled (f<sub>OSC2</sub> on I/O port)

# Bits 6:5 = CP[1:0] CPU clock prescaler

These bits select the CPU clock prescaler which is applied in the different slow modes. Their action is conditioned by the setting of the SMS bit. These two bits are set and cleared by software

f <sub>CPU</sub> in SLOW mode	CP1	CP0
f <sub>OSC2</sub> / 2	0	0
f <sub>OSC2</sub> / 4	0	1
f <sub>OSC2</sub> / 8	1	0
f <sub>OSC2</sub> / 16	1	1

#### Bit 4 = **SMS** *Slow mode select*

This bit is set and cleared by software. 0: Normal mode.  $f_{CPU} = f_{OSC2}$ 1: Slow mode.  $f_{CPU}$  is given by CP1, CP0 See Section 8.2 "SLOW MODE" and Section 10.2 "MAIN CLOCK CONTROLLER WITH REAL TIME CLOCK MCC/RTC" for more details.

# Bits 3:2 = **TB[1:0]** *Time base control*

These bits select the programmable divider time base. They are set and cleared by software.

Counter	Time	TB1	тво	
Prescaler	f <sub>OSC2</sub> =4 MHz	f <sub>OSC2</sub> =8 MHz	101	100
16000	4ms	2ms	0	0
32000	8ms	4ms	0	1
80000	20ms	10ms	1	0
200000	50ms	25ms	1	1

A modification of the time base is taken into account at the end of the current period (previously set) to avoid an unwanted time shift. This allows to use this time base as a real time clock.

Bit 1 = **OIE** Oscillator interrupt enable

This bit set and cleared by software.

0: Oscillator interrupt disabled

1: Oscillator interrupt enabled

This interrupt can be used to exit from ACTIVE HALT mode.

When this bit is set, calling the ST7 software HALT instruction enters the ACTIVE HALT power saving mode.

**CAUTION:** The BRES and BSET instructions

must not be used on the MCCSR register to avoid

unintentionally clearing the OIF bit.

# MAIN CLOCK CONTROLLER WITH REAL TIME CLOCK (Cont'd)

#### Bit 0 = **OIF** Oscillator interrupt flag

This bit is set by hardware and cleared by software reading the CSR register. It indicates when set that the main oscillator has reached the selected elapsed time (TB1:0).

0: Timeout not reached

1: Timeout reached

#### Table 15. Main Clock Controller Register Map and Reset Values

# **10.3 PWM AUTO-RELOAD TIMER (ART)**

#### 10.3.1 Introduction

The Pulse Width Modulated Auto-Reload Timer on-chip peripheral consists of an 8-bit auto reload counter with compare/capture capabilities and of a 7-bit prescaler clock source.

These resources allow five possible operating modes:

- Generation of up to four independent PWM signals
- Output compare and Time base interrupt
- Up to two input capture functions
- External event detector
- Up to two external interrupt sources

The three first modes can be used together with a single counter frequency.

The timer can be used to wake up the MCU from WAIT and HALT modes.

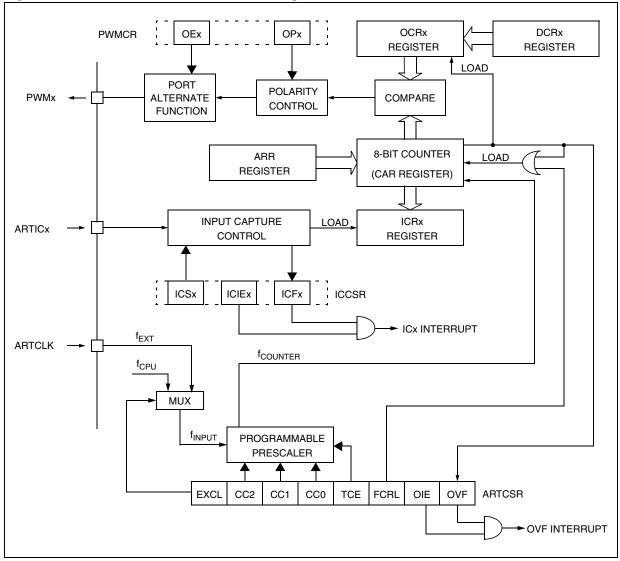

Figure 40. PWM Auto-Reload Timer Block Diagram

# **10.3.2 Functional Description**

#### Counter

The free running 8-bit counter is fed by the output of the prescaler, and is incremented on every rising edge of the clock signal.

It is possible to read or write the contents of the counter on the fly by reading or writing the Counter Access register (ARTCAR).

When a counter overflow occurs, the counter is automatically reloaded with the contents of the ARTARR register (the prescaler is not affected).

#### Counter clock and prescaler

The counter clock frequency is given by:

$$f_{COUNTER} = f_{INPUT} / 2^{CC[2:0]}$$

The timer counter's input clock ( $f_{INPUT}$ ) feeds the 7-bit programmable prescaler, which selects one of the eight available taps of the prescaler, as defined by CC[2:0] bits in the Control/Status Register (ARTCSR). Thus the division factor of the prescaler can be set to 2<sup>n</sup> (where n = 0, 1,..7).

This  $f_{INPUT}$  frequency source is selected through the EXCL bit of the ARTCSR register and can be either the  $f_{CPU}$  or an external input frequency  $f_{FXT}$ .

The clock input to the counter is enabled by the TCE (Timer Counter Enable) bit in the ARTCSR register. When TCE is reset, the counter is stopped and the prescaler and counter contents are frozen. When TCE is set, the counter runs at the rate of the selected clock source.

# **Counter and Prescaler Initialization**

After RESET, the counter and the prescaler are cleared and  $f_{INPUT} = f_{CPU}$ .

The counter can be initialized by:

- Writing to the ARTARR register and then setting the FCRL (Force Counter Re-Load) and the TCE (Timer Counter Enable) bits in the ARTCSR register.
- Writing to the ARTCAR counter access register,

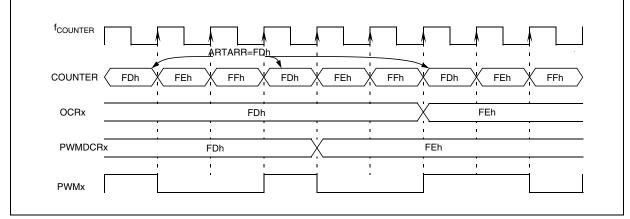

In both cases the 7-bit prescaler is also cleared, whereupon counting will start from a known value.

Direct access to the prescaler is not possible.

# **Output compare control**

The timer compare function is based on four different comparisons with the counter (one for each PWMx output). Each comparison is made between the counter value and an output compare register (OCRx) value. This OCRx register can not be accessed directly, it is loaded from the duty cycle register (PWMDCRx) at each overflow of the counter.

This double buffering method avoids glitch generation when changing the duty cycle on the fly.

# Figure 41. Output Compare Control

57/

# Independent PWM signal generation

This mode allows up to four Pulse Width Modulated signals to be generated on the PWMx output pins with minimum core processing overhead. This function is stopped during HALT mode.

Each PWMx output signal can be selected independently using the corresponding OEx bit in the PWM Control register (PWMCR). When this bit is set, the corresponding I/O pin is configured as output push-pull alternate function.

The PWM signals all have the same frequency which is controlled by the counter period and the ARTARR register value.

 $f_{PWM} = f_{COUNTER} / (256 - ARTARR)$ 

When a counter overflow occurs, the PWMx pin level is changed depending on the corresponding OPx (output polarity) bit in the PWMCR register.

Figure 42. PWM Auto-reload Timer Function

When the counter reaches the value contained in one of the output compare register (OCRx) the corresponding PWMx pin level is restored.

It should be noted that the reload values will also affect the value and the resolution of the duty cycle of the PWM output signal. To obtain a signal on a PWMx pin, the contents of the OCRx register must be greater than the contents of the ARTARR register.

The maximum available resolution for the PWMx duty cycle is:

Resolution = 1 / (256 - ARTARR)

**Note**: To get the maximum resolution (1/256), the ARTARR register must be 0. With this maximum resolution, 0% and 100% can be obtained by changing the polarity.

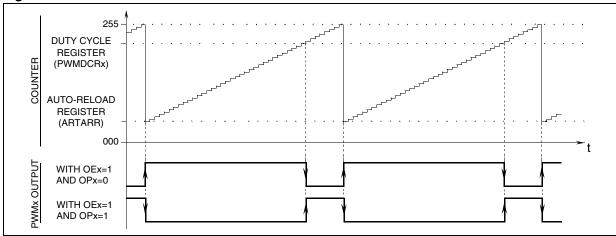

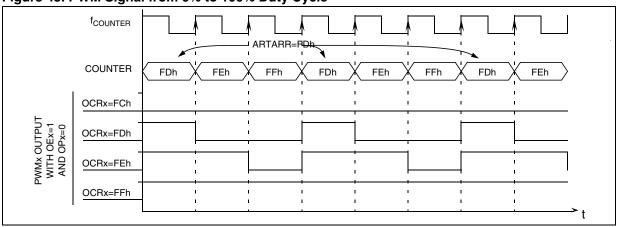

Figure 43. PWM Signal from 0% to 100% Duty Cycle

57

# **Output compare and Time base interrupt**

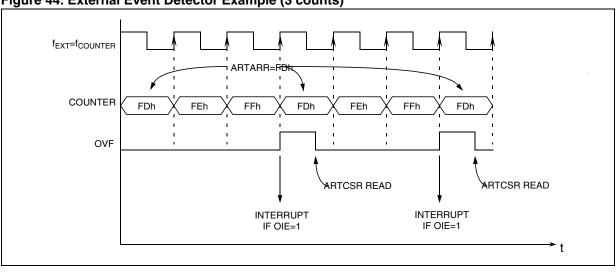

On overflow, the OVF flag of the ARTCSR register is set and an overflow interrupt request is generated if the overflow interrupt enable bit, OIE, in the ARTCSR register, is set. The OVF flag must be reset by the user software. This interrupt can be used as a time base in the application.

#### External clock and event detector mode

Using the  $f_{EXT}$  external prescaler input clock, the auto-reload timer can be used as an external clock event detector. In this mode, the ARTARR register is used to select the  $n_{EVENT}$  number of events to be counted before setting the OVF flag.

# $n_{EVENT} = 256 - ARTARR$

**Caution:** The external clock function is not available in HALT mode. If HALT mode is used in the application, prior to executing the HALT instruction, the counter must be disabled by clearing the TCE bit in the ARTCSR register to avoid spurious counter increments.

#### Figure 44. External Event Detector Example (3 counts)

#### Input Capture Function

Input Capture mode allows the measurement of external signal pulse widths through ARTICRx registers.

Each input capture can generate an interrupt independently on a selected input signal transition. This event is flagged by a set of the corresponding CFx bits of the Input Capture Control/Status register (ARTICCSR).

These input capture interrupts are enabled through the CIEx bits of the ARTICCSR register.

The active transition (falling or rising edge) is software programmable through the CSx bits of the ARTICCSR register.

The read only input capture registers (ARTICRx) are used to latch the auto-reload counter value when a transition is detected on the ARTICx pin (CFx bit set in ARTICCSR register). After fetching the interrupt vector, the CFx flags can be read to identify the interrupt source.

**Note:** After a capture detection, data transfer in the ARTICRx register is inhibited until the next read (clearing the CFx bit).

The timer interrupt remains pending while the CFx flag is set when the interrupt is enabled (CIEx bit

set). This means, the ARTICRx register has to be read at each capture event to clear the CFx flag.

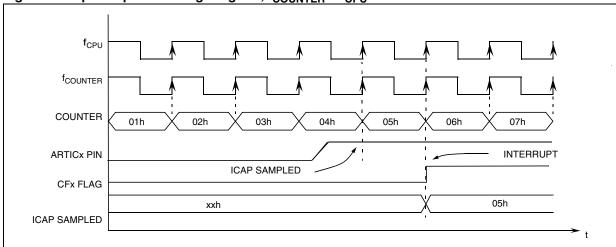

The timing resolution is given by auto-reload counter cycle time  $(1/f_{COUNTER})$ .

**Note:** During HALT mode, input capture is inhibited (the ARTICRx is never reloaded) and only the external interrupt capability can be used.

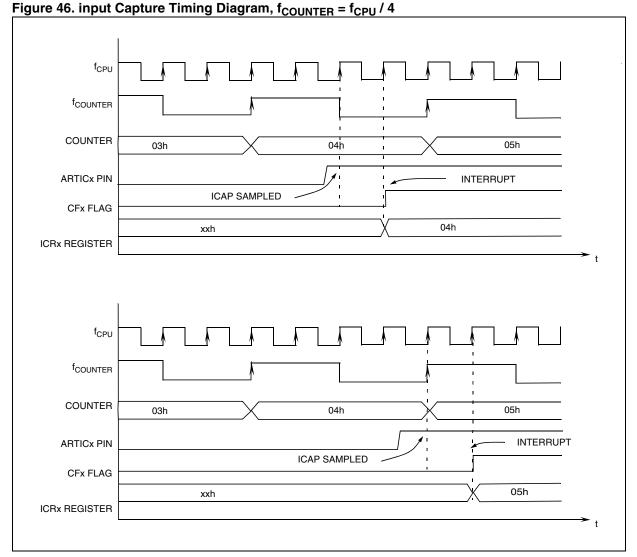

**Note:** The ARTICx signal is synchronized on CPU clock. It takes two rising edges until ARTICRx is latched with the counter value. Depending on the prescaler value and the time when the ICAP event occurs, the value loaded in the ARTICRx register may be different.

If the counter is clocked with the CPU clock, the value latched in ARTICRx is always the next counter value after the event on ARTICx occurred (Figure 45).

If the counter clock is prescaled, it depends on the position of the ARTICx event within the counter cycle (Figure 46).

# Figure 45. Input Capture Timing Diagram, f<sub>COUNTER</sub> = f<sub>CPU</sub>

#### **External Interrupt Capability**

57/

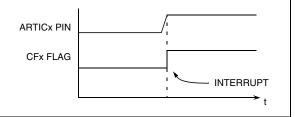

This mode allows the Input capture capabilities to be used as external interrupt sources. The interrupts are generated on the edge of the ARTICx signal.

The edge sensitivity of the external interrupts is programmable (CSx bit of ARTICCSR register) and they are independently enabled through CIEx bits of the ARTICCSR register. After fetching the interrupt vector, the CFx flags can be read to identify the interrupt source.

During HALT mode, the external interrupts can be used to wake up the micro (if the CIEx bit is set). In

this case, the interrupt synchronization is done directly on the ARTICx pin edge (Figure 47).

## 10.3.3 Register Description

# **CONTROL / STATUS REGISTER (ARTCSR)**

Read/Write

Reset Value: 0000 0000 (00h)

7							0
EXCL	CC2	CC1	CC0	TCE	FCRL	OIE	OVF

#### Bit 7 = **EXCL** External Clock

This bit is set and cleared by software. It selects the input clock for the 7-bit prescaler.

0: CPU clock.

1: External clock.

Bit 6:4 = **CC[2:0]** Counter Clock Control These bits are set and cleared by software. They determine the prescaler division ratio from  $f_{INPUT}$ .

fCOUNTER	With f <sub>INPUT</sub> =8 MHz	CC2	CC1	CC0
f <sub>INPUT</sub>	8 MHz	0	0	0
f <sub>INPUT</sub> / 2	4 MHz	0	0	1
f <sub>INPUT</sub> / 4	2 MHz	0	1	0
f <sub>INPUT</sub> / 8	1 MHz	0	1	1
f <sub>INPUT</sub> / 16	500 kHz	1	0	0
f <sub>INPUT</sub> / 32	250 kHz	1	0	1
f <sub>INPUT</sub> / 64	125 kHz	1	1	0
f <sub>INPUT</sub> / 128	62.5 kHz	1	1	1

#### Bit 3 = **TCE** Timer Counter Enable

This bit is set and cleared by software. It puts the timer in the lowest power consumption mode.

0: Counter stopped (prescaler and counter frozen). 1: Counter running.

#### Bit 2 = FCRL Force Counter Re-Load

This bit is write-only and any attempt to read it will yield a logical zero. When set, it causes the contents of ARTARR register to be loaded into the counter, and the content of the prescaler register to be cleared in order to initialize the timer before starting to count.

#### Bit 1 = OIE Overflow Interrupt Enable

This bit is set and cleared by software. It allows to enable/disable the interrupt which is generated when the OVF bit is set.

0: Overflow Interrupt disable.

1: Overflow Interrupt enable.

#### Bit 0 = **OVF** Overflow Flag

This bit is set by hardware and cleared by software reading the ARTCSR register. It indicates the transition of the counter from FFh to the ARTARR value.

#### 0: New transition not yet reached

1: Transition reached

# COUNTER ACCESS REGISTER (ARTCAR)

Read/Write

Reset Value: 0000 0000 (00h)

7							0
CA7	CA6	CA5	CA4	CA3	CA2	CA1	CA0

Bit 7:0 = CA[7:0] Counter Access Data

These bits can be set and cleared either by hardware or by software. The ARTCAR register is used to read or write the auto-reload counter "on the fly" (while it is counting).

# AUTO-RELOAD REGISTER (ARTARR)

Read/Write

Reset Value: 0000 0000 (00h)

7							0
AR7	AR6	AR5	AR4	AR3	AR2	AR1	AR0

# Bit 7:0 = AR[7:0] Counter Auto-Reload Data

These bits are set and cleared by software. They are used to hold the auto-reload value which is automatically loaded in the counter when an overflow occurs. At the same time, the PWM output levels are changed according to the corresponding OPx bit in the PWMCR register.

This register has two PWM management functions:

- Adjusting the PWM frequency
- Setting the PWM duty cycle resolution

PWM Frequency vs Resolution:

ARTARR	Resolution	f <sub>P\</sub>	мм
value	Resolution	Min	Max
0	8-bit	~0.244 kHz	31.25 kHz
[ 0127 ]	> 7-bit	~0.244 kHz	62.5 kHz
[ 128191 ]	> 6-bit	~0.488 kHz	125 kHz
[ 192223 ]	> 5-bit	~0.977 kHz	250 kHz
[ 224239 ]	> 4-bit	~1.953 kHz	500 kHz

# PWM CONTROL REGISTER (PWMCR)

Read/Write

5/

Reset Value: 0000 0000 (00h)

7							0
OE3	OE2	OE1	OE0	OP3	OP2	OP1	OP0

#### Bit 7:4 = OE[3:0] PWM Output Enable

These bits are set and cleared by software. They enable or disable the PWM output channels independently acting on the corresponding I/O pin. 0: PWM output disabled.

1: PWM output enabled.

# Bit 3:0 = OP[3:0] PWM Output Polarity

These bits are set and cleared by software. They independently select the polarity of the four PWM output signals.

PWMx ou	OPx	
Counter <= OCRx	Counter > OCRx	
1	0	0
0	1	1

**Note**: When an OPx bit is modified, the PWMx output signal polarity is immediately reversed.

# **DUTY CYCLE REGISTERS (PWMDCRx)**

Read/Write

Reset Value: 0000 0000 (00h)

# Bit 7:0 = DC[7:0] Duty Cycle Data

These bits are set and cleared by software.

A PWMDCRx register is associated with the OCRx register of each PWM channel to determine the second edge location of the PWM signal (the first edge location is common to all channels and given by the ARTARR register). These PWMDCR registers allow the duty cycle to be set independently for each PWM channel.

# INPUT CAPTURE CONTROL / STATUS REGISTER (ARTICCSR)

Read/Write

Reset Value: 0000 0000 (00h)

7							0
0	0	CS2	CS1	CIE2	CIE1	CF2	CF1

Bit 7:6 = Reserved, always read as 0.

#### Bit 5:4 = CS[2:1] Capture Sensitivity

These bits are set and cleared by software. They determine the trigger event polarity on the corresponding input capture channel.

0: Falling edge triggers capture on channel x.

1: Rising edge triggers capture on channel x.

Bit 3:2 = **CIE[2:1]** Capture Interrupt Enable These bits are set and cleared by software. They enable or disable the Input capture channel inter-

rupts independently. 0: Input capture channel x interrupt disabled.

1: Input capture channel x interrupt enabled.

#### Bit 1:0 = CF[2:1] Capture Flag

These bits are set by hardware and cleared by software reading the corresponding ARTICRx register. Each CFx bit indicates that an input capture x has occurred.

0: No input capture on channel x.

1: An input capture has occurred on channel x.

#### **INPUT CAPTURE REGISTERS (ARTICRx)**

Read only

Reset Value: 0000 0000 (00h)

7							0
IC7	IC6	IC5	IC4	IC3	IC2	IC1	IC0

Bit 7:0 = IC[7:0] Input Capture Data

These read only bits are set and cleared by hardware. An ARTICRx register contains the 8-bit auto-reload counter value transferred by the input capture channel x event.

57

# 10.4 16-BIT TIMER

#### **10.4.1 Introduction**

The timer consists of a 16-bit free-running counter driven by a programmable prescaler.

It may be used for a variety of purposes, including pulse length measurement of up to two input signals (*input capture*) or generation of up to two output waveforms (*output compare* and *PWM*).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the CPU clock prescaler.

Some ST7 devices have two on-chip 16-bit timers. They are completely independent, and do not share any resources. They are synchronized after a MCU reset as long as the timer clock frequencies are not modified.

This description covers one or two 16-bit timers. In ST7 devices with two timers, register names are prefixed with TA (Timer A) or TB (Timer B).

#### 10.4.2 Main Features

- Programmable prescaler: f<sub>CPU</sub> divided by 2, 4 or 8
- Overflow status flag and maskable interrupt
- External clock input (must be at least four times slower than the CPU clock speed) with the choice of active edge
- 1 or 2 Output Compare functions each with:
  - 2 dedicated 16-bit registers
  - 2 dedicated programmable signals
  - 2 dedicated status flags
  - 1 dedicated maskable interrupt
- 1 or 2 Input Capture functions each with:
  - 2 dedicated 16-bit registers
  - 2 dedicated active edge selection signals
  - 2 dedicated status flags
  - 1 dedicated maskable interrupt
- Pulse width modulation mode (PWM)
- One Pulse mode
- Reduced Power Mode
- 5 alternate functions on I/O ports (ICAP1, ICAP2, OCMP1, OCMP2, EXTCLK)\*

The Block Diagram is shown in Figure 1.

\*Note: Some timer pins may not be available (not bonded) in some ST7 devices. Refer to the device pin out description.

When reading an input signal on a non-bonded pin, the value will always be '1'.

#### **10.4.3 Functional Description**

#### 10.4.3.1 Counter

The main block of the Programmable Timer is a 16-bit free running upcounter and its associated 16-bit registers. The 16-bit registers are made up of two 8-bit registers called high and low.

Counter Register (CR):

- Counter High Register (CHR) is the most significant byte (MS Byte).
- Counter Low Register (CLR) is the least significant byte (LS Byte).

Alternate Counter Register (ACR)

- Alternate Counter High Register (ACHR) is the most significant byte (MS Byte).
- Alternate Counter Low Register (ACLR) is the least significant byte (LS Byte).

These two read-only 16-bit registers contain the same value but with the difference that reading the ACLR register does not clear the TOF bit (Timer overflow flag), located in the Status register, (SR), (see note at the end of paragraph titled 16-bit read sequence).

Writing in the CLR register or ACLR register resets the free running counter to the FFFCh value. Both counters have a reset value of FFFCh (this is the only value which is reloaded in the 16-bit time

the only value which is reloaded in the 16-bit timer). The reset value of both counters is also FFFCh in One Pulse mode and PWM mode.

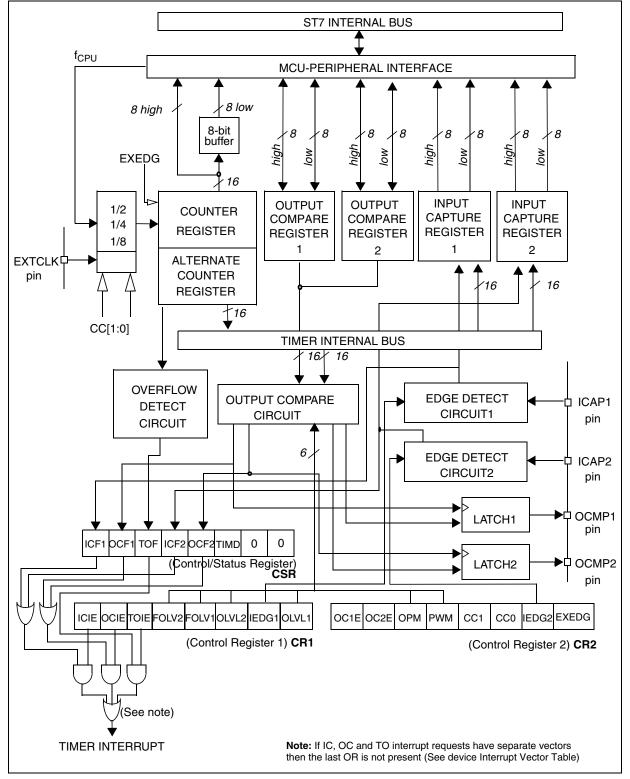

The timer clock depends on the clock control bits of the CR2 register, as illustrated in Table 1. The value in the counter register repeats every 131072, 262144 or 524288 CPU clock cycles depending on the CC[1:0] bits.

The timer frequency can be  $f_{CPU}/2$ ,  $f_{CPU}/4$ ,  $f_{CPU}/8$  or an external frequency.

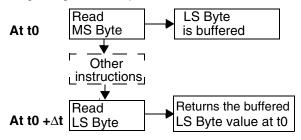

**لرک**ا

## Figure 48. Timer Block Diagram

**16-bit read sequence:** (from either the Counter Register or the Alternate Counter Register).

#### Beginning of the sequence

Sequence completed

The user must read the MS Byte first, then the LS Byte value is buffered automatically.

This buffered value remains unchanged until the 16-bit read sequence is completed, even if the user reads the MS Byte several times.

After a complete reading sequence, if only the CLR register or ACLR register are read, they return the LS Byte of the count value at the time of the read.

Whatever the timer mode used (input capture, output compare, One Pulse mode or PWM mode) an overflow occurs when the counter rolls over from FFFFh to 0000h then:

- The TOF bit of the SR register is set.
- A timer interrupt is generated if:
  - TOIE bit of the CR1 register is set and
  - I bit of the CC register is cleared.

If one of these conditions is false, the interrupt remains pending to be issued as soon as they are both true. Clearing the overflow interrupt request is done in two steps:

1. Reading the SR register while the TOF bit is set. 2. An access (read or write) to the CLR register.

**Notes:** The TOF bit is not cleared by accesses to ACLR register. The advantage of accessing the ACLR register rather than the CLR register is that it allows simultaneous use of the overflow function and reading the free running counter at random times (for example, to measure elapsed time) without the risk of clearing the TOF bit erroneously.

The timer is not affected by WAIT mode.

In HALT mode, the counter stops counting until the mode is exited. Counting then resumes from the previous count (MCU awakened by an interrupt) or from the reset count (MCU awakened by a Reset).

#### 10.4.3.2 External Clock

The external clock (where available) is selected if CC0 = 1 and CC1 = 1 in the CR2 register.

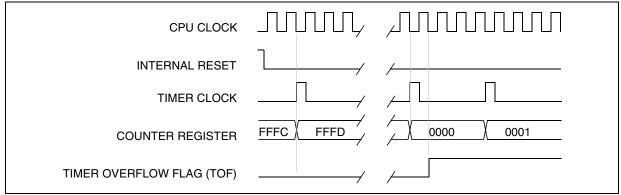

The status of the EXEDG bit in the CR2 register determines the type of level transition on the external clock pin EXTCLK that will trigger the free running counter.

The counter is synchronized with the falling edge of the internal CPU clock.

A minimum of four falling edges of the CPU clock must occur between two consecutive active edges of the external clock; thus the external clock frequency must be less than a quarter of the CPU clock frequency.

Note: The MCU is in reset state when the internal reset signal is high, when it is low the MCU is running.

#### 10.4.3.3 Input Capture

In this section, the index, *i*, may be 1 or 2 because there are two input capture functions in the 16-bit timer.

The two 16-bit input capture registers (IC1R and IC2R) are used to latch the value of the free running counter after a transition is detected on the ICAP*i* pin (see figure 5).

	MS Byte	LS Byte
ICiR	IC <i>i</i> HR	IC <i>i</i> LR

ICiR register is a read-only register.

The active transition is software programmable through the IEDG*i* bit of Control Registers (CR*i*).

Timing resolution is one count of the free running counter: ( $f_{CPU}/CC[1:0]$ ).

#### **Procedure:**

To use the input capture function select the following in the CR2 register:

- Select the timer clock (CC[1:0]) (see Table 1).
- Select the edge of the active transition on the ICAP2 pin with the IEDG2 bit (the ICAP2 pin must be configured as floating input or input with pull-up without interrupt if this configuration is available).

And select the following in the CR1 register:

- Set the ICIE bit to generate an interrupt after an input capture coming from either the ICAP1 pin or the ICAP2 pin
- Select the edge of the active transition on the ICAP1 pin with the IEDG1 bit (the ICAP1pin must be configured as floating input or input with pullup without interrupt if this configuration is available).

When an input capture occurs:

- ICFi bit is set.
- The IC*i*R register contains the value of the free running counter on the active transition on the ICAP*i* pin (see Figure 6).
- A timer interrupt is generated if the ICIE bit is set and the I bit is cleared in the CC register. Otherwise, the interrupt remains pending until both conditions become true.

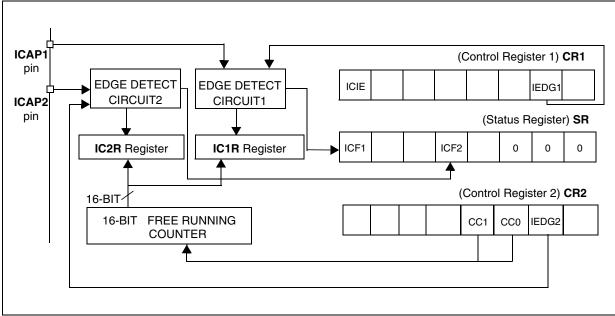

Clearing the Input Capture interrupt request (that is, clearing the ICF*i* bit) is done in two steps:

- 1. Reading the SR register while the ICF*i* bit is set.
- 2. An access (read or write) to the ICiLR register.

#### Notes:

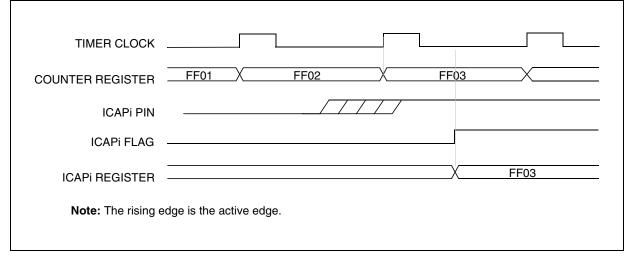

- 1. After reading the IC*i*HR register, transfer of input capture data is inhibited and ICF*i* will never be set until the IC*i*LR register is also read.
- 2. The IC*i*R register contains the free running counter value which corresponds to the most recent input capture.
- 3. The two input capture functions can be used together even if the timer also uses the two output compare functions.
- 4. In One Pulse mode and PWM mode only Input Capture 2 can be used.
- 5. The alternate inputs (ICAP1 and ICAP2) are always directly connected to the timer. So any transitions on these pins activates the input capture function. Moreover if one of the ICAP*i* pins is configured as an input and the second one as an output, an interrupt can be generated if the user toggles the output pin and if the ICIE bit is set. This can be avoided if the input capture function *i* is disabled by reading the IC*i*HR (see note 1).
- 6. The TOF bit can be used with interrupt generation in order to measure events that go beyond the timer range (FFFFh).

## Figure 53. Input Capture Timing Diagram

5/

#### 10.4.3.4 Output Compare

In this section, the index, *i*, may be 1 or 2 because there are two output compare functions in the 16-bit timer.

This function can be used to control an output waveform or indicate when a period of time has elapsed.

When a match is found between the Output Compare register and the free running counter, the output compare function:

- Assigns pins with a programmable value if the OC/E bit is set
- Sets a flag in the status register
- Generates an interrupt if enabled

Two 16-bit registers Output Compare Register 1 (OC1R) and Output Compare Register 2 (OC2R) contain the value to be compared to the counter register each timer clock cycle.

	MS Byte	LS Byte
OC <i>i</i> R	OC <i>i</i> HR	OC <i>i</i> LR

These registers are readable and writable and are not affected by the timer hardware. A reset event changes the OC*i*R value to 8000h.

Timing resolution is one count of the free running counter:  $(f_{CPU/CC[1:0]})$ .

#### **Procedure:**

To use the output compare function, select the following in the CR2 register:

- Set the OC*i*E bit if an output is needed then the OCMP*i* pin is dedicated to the output compare *i* signal.
- Select the timer clock (CC[1:0]) (see Table 1).

And select the following in the CR1 register:

- Select the OLVL*i* bit to applied to the OCMP*i* pins after the match occurs.
- Set the OCIE bit to generate an interrupt if it is needed.

When a match is found between OCRi register and CR register:

OCF*i* bit is set.

- The OCMP*i* pin takes OLVL*i* bit value (OCMP*i* pin latch is forced low during reset).
- A timer interrupt is generated if the OCIE bit is set in the CR1 register and the I bit is cleared in the CC register (CC).

The OC*i*R register value required for a specific timing application can be calculated using the following formula:

$$\Delta \operatorname{OC}_{i} R = \frac{\Delta t * f_{CPU}}{PRESC}$$

Where:

 $\Delta t$  = Output compare period (in seconds)

 $f_{CPU}$  = CPU clock frequency (in hertz)

If the timer clock is an external clock, the formula is:

$$\Delta \text{ OC}/\text{R} = \Delta t * f_{\text{EXT}}$$

Where:

 $\Delta t$  = Output compare period (in seconds)

f<sub>EXT</sub> = External timer clock frequency (in hertz)

Clearing the output compare interrupt request (that is, clearing the OCF*i* bit) is done by:

- 1. Reading the SR register while the OCF*i* bit is set.
- 2. An access (read or write) to the OCiLR register.

The following procedure is recommended to prevent the OCF*i* bit from being set between the time it is read and the write to the OC*i*R register:

- Write to the OC*i*HR register (further compares are inhibited).
- Read the SR register (first step of the clearance of the OCF*i* bit, which may be already set).
- Write to the OC*i*LR register (enables the output compare function and clears the OCF*i* bit).

## Notes:

57/

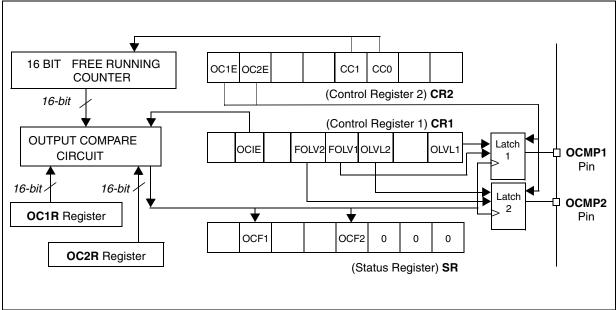

- 1. After a processor write cycle to the OC*i*HR register, the output compare function is inhibited until the OC*i*LR register is also written.
- 2. If the OC*i*E bit is not set, the OCMP*i* pin is a general I/O port and the OLVL*i* bit will not appear when a match is found but an interrupt could be generated if the OCIE bit is set.
- 3. When the timer clock is f<sub>CPU</sub>/2, OCF*i* and OCMP*i* are set while the counter value equals the OC*i*R register value (see Figure 8). This behavior is the same in OPM or PWM mode. When the timer clock is f<sub>CPU</sub>/4, f<sub>CPU</sub>/8 or in external clock mode, OCF*i* and OCMP*i* are set while the counter value equals the OC*i*R register value plus 1 (see Figure 9).
- 4. The output compare functions can be used both for generating external events on the OCMP*i* pins even if the input capture mode is also used.
- 5. The value in the 16-bit OC*i*R register and the OLV*i* bit should be changed after each successful comparison in order to control an output waveform or establish a new elapsed timeout.

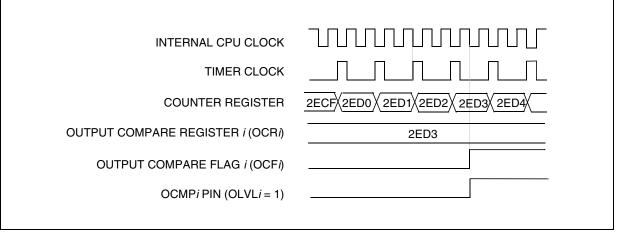

### Forced Compare Output capability

When the FOLV*i* bit is set by software, the OLVL*i* bit is copied to the OCMP*i* pin. The OLV*i* bit has to be toggled in order to toggle the OCMP*i* pin when it is enabled (OC*i*E bit = 1). The OCF*i* bit is then not set by hardware, and thus no interrupt request is generated.

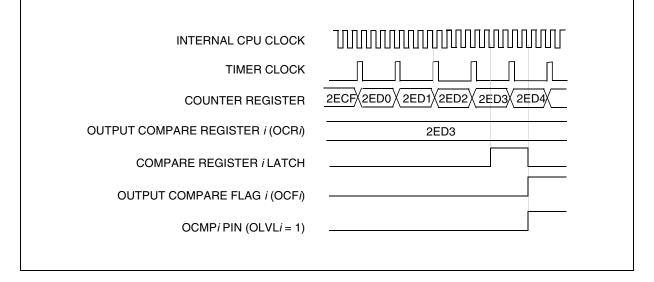

The FOLVL*i* bits have no effect in both One Pulse mode and PWM mode.

## Figure 55. Output Compare Timing Diagram, $f_{TIMER} = f_{CPU}/2$

## Figure 56. Output Compare Timing Diagram, $f_{TIMER} = f_{CPU}/4$

#### 10.4.3.5 One Pulse Mode

One Pulse mode enables the generation of a pulse when an external event occurs. This mode is selected via the OPM bit in the CR2 register.

The One Pulse mode uses the Input Capture1 function and the Output Compare1 function.

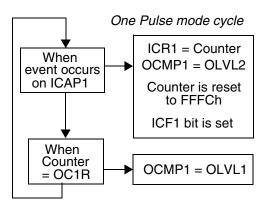

#### Procedure:

To use One Pulse mode:

- 1. Load the OC1R register with the value corresponding to the length of the pulse (see the formula in the opposite column).
- 2. Select the following in the CR1 register:
  - Using the OLVL1 bit, select the level to be applied to the OCMP1 pin after the pulse.
  - Using the OLVL2 bit, select the level to be applied to the OCMP1 pin during the pulse.
  - Select the edge of the active transition on the ICAP1 pin with the IEDG1 bit (the ICAP1 pin must be configured as floating input).
- 3. Select the following in the CR2 register:
  - Set the OC1E bit, the OCMP1 pin is then dedicated to the Output Compare 1 function.
  - Set the OPM bit.

57/

- Select the timer clock CC[1:0] (see Table 1).

Then, on a valid event on the ICAP1 pin, the counter is initialized to FFFCh and OLVL2 bit is loaded on the OCMP1 pin, the ICF1 bit is set and the value FFFDh is loaded in the IC1R register.

Because the ICF1 bit is set when an active edge occurs, an interrupt can be generated if the ICIE bit is set.

Clearing the Input Capture interrupt request (that is, clearing the ICF*i* bit) is done in two steps:

1. Reading the SR register while the ICF*i* bit is set.

2. An access (read or write) to the ICiLR register.

The OC1R register value required for a specific timing application can be calculated using the following formula:

Where:

t = Pulse period (in seconds)

f<sub>CPU</sub> = CPU clock frequency (in hertz)

PRESC = Timer prescaler factor (2, 4 or 8 depending on the CC[1:0] bits, see Table 1)

If the timer clock is an external clock the formula is:

$$OC_{iR} = t * f_{EXT} - 5$$

Where:

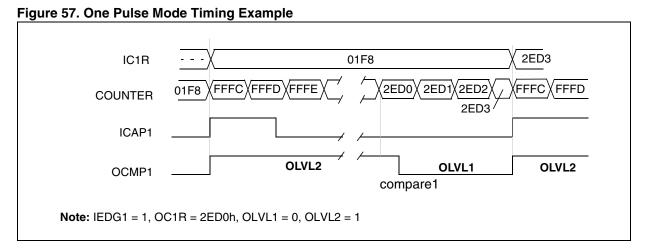

t = Pulse period (in seconds)

f<sub>EXT</sub> = External timer clock frequency (in hertz)

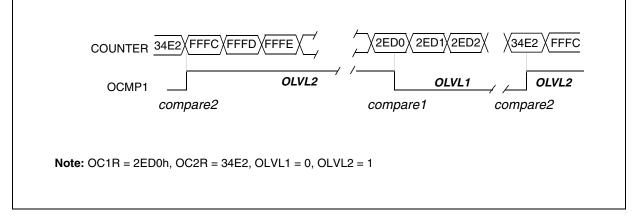

When the value of the counter is equal to the value of the contents of the OC1R register, the OLVL1 bit is output on the OCMP1 pin, (See Figure 10).

#### Notes:

- 1. The OCF1 bit cannot be set by hardware in One Pulse mode but the OCF2 bit can generate an Output Compare interrupt.
- 2. When the Pulse Width Modulation (PWM) and One Pulse mode (OPM) bits are both set, the PWM mode is the only active one.
- 3. If OLVL1 = OLVL2 a continuous signal will be seen on the OCMP1 pin.
- 4. The ICAP1 pin can not be used to perform input capture. The ICAP2 pin can be used to perform input capture (ICF2 can be set and IC2R can be loaded) but the user must take care that the counter is reset each time a valid edge occurs on the ICAP1 pin and ICF1 can also generates interrupt if ICIE is set.
- 5. When One Pulse mode is used OC1R is dedicated to this mode. Nevertheless OC2R and OCF2 can be used to indicate a period of time has been elapsed but cannot generate an output waveform because the level OLVL2 is dedicated to the One Pulse mode.

## Figure 58. Pulse Width Modulation Mode Timing Example with 2 Output Compare Functions

**Note:** On timers with only one Output Compare register, a fixed frequency PWM signal can be generated using the output compare and the counter overflow to define the pulse length.

#### 10.4.3.6 Pulse Width Modulation Mode

Pulse Width Modulation (PWM) mode enables the generation of a signal with a frequency and pulse length determined by the value of the OC1R and OC2R registers.

Pulse Width Modulation mode uses the complete Output Compare 1 function plus the OC2R register, and so this functionality can not be used when PWM mode is activated.

In PWM mode, double buffering is implemented on the output compare registers. Any new values written in the OC1R and OC2R registers are taken into account only at the end of the PWM period (OC2) to avoid spikes on the PWM output pin (OCMP1).

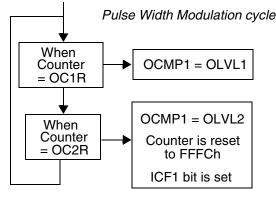

#### Procedure

To use Pulse Width Modulation mode:

- 1. Load the OC2R register with the value corresponding to the period of the signal using the formula in the opposite column.
- 2. Load the OC1R register with the value corresponding to the period of the pulse if (OLVL1 = 0 and OLVL2 = 1) using the formula in the opposite column.
- 3. Select the following in the CR1 register:
  - Using the OLVL1 bit, select the level to be applied to the OCMP1 pin after a successful comparison with the OC1R register.
  - Using the OLVL2 bit, select the level to be applied to the OCMP1 pin after a successful comparison with the OC2R register.
- 4. Select the following in the CR2 register:
  - Set OC1E bit: the OCMP1 pin is then dedicated to the output compare 1 function.
  - Set the PWM bit.

5/

- Select the timer clock (CC[1:0]) (see Table 1).

If OLVL1 = 1 and OLVL2 = 0 the length of the positive pulse is the difference between the OC2R and OC1R registers.

If OLVL1 = OLVL2 a continuous signal will be seen on the OCMP1 pin.

The OC*i*R register value required for a specific timing application can be calculated using the following formula:

$$OCiR Value = \frac{t \cdot f_{CPU}}{PRESC} - 5$$

Where:

t = Signal or pulse period (in seconds)

f<sub>CPU</sub> = CPU clock frequency (in hertz)

PRESC = Timer prescaler factor (2, 4 or 8 depending on CC[1:0] bits, see Table 1)

If the timer clock is an external clock the formula is:

$$OC_iR = t * f_{EXT} - 5$$

Where:

t = Signal or pulse period (in seconds)

f<sub>EXT</sub> = External timer clock frequency (in hertz)

The Output Compare 2 event causes the counter to be initialized to FFFCh (See Figure 11)

#### Notes:

- 1. After a write instruction to the OC*i*HR register, the output compare function is inhibited until the OC*i*LR register is also written.
- 2. The OCF1 and OCF2 bits cannot be set by hardware in PWM mode therefore the Output Compare interrupt is inhibited.
- 3. The ICF1 bit is set by hardware when the counter reaches the OC2R value and can produce a timer interrupt if the ICIE bit is set and the I bit is cleared.
- 4. In PWM mode the ICAP1 pin can not be used to perform input capture because it is disconnected to the timer. The ICAP2 pin can be used to perform input capture (ICF2 can be set and IC2R can be loaded) but the user must take care that the counter is reset each period and ICF1 can also generates interrupt if ICIE is set.
- 5. When the Pulse Width Modulation (PWM) and One Pulse mode (OPM) bits are both set, the PWM mode is the only active one.

#### 10.4.4 Low Power Modes

Mode	Description
WAIT	No effect on 16-bit Timer. Timer interrupts cause the device to exit from WAIT mode.
	16-bit Timer registers are frozen.
HALT	In HALT mode, the counter stops counting until Halt mode is exited. Counting resumes from the previous count when the MCU is woken up by an interrupt with "exit from HALT mode" capability or from the counter reset value when the MCU is woken up by a RESET.
	If an input capture event occurs on the ICAP <i>i</i> pin, the input capture detection circuitry is armed. Consequently, when the MCU is woken up by an interrupt with "exit from HALT mode" capability, the ICF <i>i</i> bit is set, and the counter value present when exiting from HALT mode is captured into the IC <i>i</i> R register.

#### 10.4.5 Interrupts

Interrupt Event	Event Flag	Enable Control Bit	Exit from Wait	Exit from Halt
Input Capture 1 event/Counter reset in PWM mode	ICF1	ICIE		
Input Capture 2 event	ICF2			No
Output Compare 1 event (not available in PWM mode)	OCF1	OCIE	Yes	
Output Compare 2 event (not available in PWM mode)	OCF2	OCIE		
Timer Overflow event	TOF	TOIE		

**Note:** The 16-bit Timer interrupt events are connected to the same interrupt vector (see Interrupts chapter). These events generate an interrupt if the corresponding Enable Control Bit is set and the interrupt mask in the CC register is reset (RIM instruction).

#### 10.4.6 Summary of Timer Modes

MODES	TIMER RESOURCES						
MODES	Input Capture 1	Input Capture 2	Output Compare 1	Output Compare 2			
Input Capture (1 and/or 2)	Yes	Yes	Yes	Yes			
Output Compare (1 and/or 2)	165	165	165	165			
One Pulse Mode	No	Not Recommended <sup>1)</sup>	No	Partially <sup>2)</sup>			
PWM Mode		Not Recommended <sup>3)</sup>	NO	No			

1) See note 4 in Section 0.1.3.5 One Pulse Mode

2) See note 5 in Section 0.1.3.5 One Pulse Mode

3) See note 4 in Section 0.1.3.6 Pulse Width Modulation Mode

#### **10.4.7 Register Description**

Each Timer is associated with three control and status registers, and with six pairs of data registers (16-bit values) relating to the two input captures, the two output compares, the counter and the alternate counter.

#### **CONTROL REGISTER 1 (CR1)**

#### Read/Write

Reset Value: 0000 0000 (00h)

7							0
ICIE	OCIE	TOIE	FOLV2	FOLV1	OLVL2	IEDG1	OLVL1

Bit 7 = ICIE Input Capture Interrupt Enable.

0: Interrupt is inhibited.

1: A timer interrupt is generated whenever the ICF1 or ICF2 bit of the SR register is set.

Bit 6 = **OCIE** *Output Compare Interrupt Enable.* 0: Interrupt is inhibited.

1: A timer interrupt is generated whenever the OCF1 or OCF2 bit of the SR register is set.

Bit 5 = **TOIE** *Timer Overflow Interrupt Enable.* 

0: Interrupt is inhibited.

1: A timer interrupt is enabled whenever the TOF bit of the SR register is set.

## Bit 4 = FOLV2 Forced Output Compare 2.

This bit is set and cleared by software.

- 0: No effect on the OCMP2 pin.
- 1: Forces the OLVL2 bit to be copied to the OCMP2 pin, if the OC2E bit is set and even if there is no successful comparison.

#### Bit 3 = FOLV1 Forced Output Compare 1.

This bit is set and cleared by software.

- 0: No effect on the OCMP1 pin.
- 1: Forces OLVL1 to be copied to the OCMP1 pin, if the OC1E bit is set and even if there is no successful comparison.

#### Bit 2 = OLVL2 Output Level 2.

This bit is copied to the OCMP2 pin whenever a successful comparison occurs with the OC2R register and OCxE is set in the CR2 register. This value is copied to the OCMP1 pin in One Pulse mode and Pulse Width Modulation mode.

#### Bit 1 = IEDG1 Input Edge 1.

This bit determines which type of level transition on the ICAP1 pin will trigger the capture.

0: A falling edge triggers the capture.

1: A rising edge triggers the capture.

#### Bit 0 = **OLVL1** Output Level 1.

The OLVL1 bit is copied to the OCMP1 pin whenever a successful comparison occurs with the OC1R register and the OC1E bit is set in the CR2 register.

## 16-BIT TIMER (Cont'd) CONTROL REGISTER 2 (CR2)

Read/Write

Reset Value: 0000 0000 (00h)

7							0
OC1E	OC2E	OPM	PWM	CC1	CC0	IEDG2	EXEDG

## Bit 7 = **OC1E** *Output Compare 1 Pin Enable.*

This bit is used only to output the signal from the timer on the OCMP1 pin (OLV1 in Output Compare mode, both OLV1 and OLV2 in PWM and one-pulse mode). Whatever the value of the OC1E bit, the Output Compare 1 function of the timer remains active.

- 0: OCMP1 pin alternate function disabled (I/O pin free for general-purpose I/O).
- 1: OCMP1 pin alternate function enabled.

#### Bit 6 = **OC2E** Output Compare 2 Pin Enable.

This bit is used only to output the signal from the timer on the OCMP2 pin (OLV2 in Output Compare mode). Whatever the value of the OC2E bit, the Output Compare 2 function of the timer remains active.

- 0: OCMP2 pin alternate function disabled (I/O pin free for general-purpose I/O).
- 1: OCMP2 pin alternate function enabled.

#### Bit 5 = **OPM** One Pulse Mode.

0: One Pulse mode is not active.

1: One Pulse mode is active, the ICAP1 pin can be used to trigger one pulse on the OCMP1 pin; the active transition is given by the IEDG1 bit. The length of the generated pulse depends on the contents of the OC1R register.

#### Bit 4 = **PWM** Pulse Width Modulation.

- 0: PWM mode is not active.
- 1: PWM mode is active, the OCMP1 pin outputs a programmable cyclic signal; the length of the pulse depends on the value of OC1R register; the period depends on the value of OC2R register.

#### Bit 3, 2 = CC[1:0] Clock Control.

The timer clock mode depends on these bits:

#### Table 17. Clock Control Bits

Timer Clock	CC1	CC0
f <sub>CPU</sub> / 4	0	0
f <sub>CPU</sub> / 2	0	1
f <sub>CPU</sub> / 8	1	0
External Clock (where available)	1	1

**Note**: If the external clock pin is not available, programming the external clock configuration stops the counter.

#### Bit 1 = IEDG2 Input Edge 2.

This bit determines which type of level transition on the ICAP2 pin will trigger the capture.

0: A falling edge triggers the capture.

1: A rising edge triggers the capture.

#### Bit 0 = EXEDG External Clock Edge.

This bit determines which type of level transition on the external clock pin EXTCLK will trigger the counter register.

0: A falling edge triggers the counter register.

1: A rising edge triggers the counter register.

## 16-BIT TIMER (Cont'd) CONTROL/STATUS REGISTER (CSR)

Read/Write (bits 7:3 read only)

Reset Value: xxxx x0xx (xxh)

7							0
ICF1	OCF1	TOF	ICF2	OCF2	TIMD	0	0

Bit 7 = ICF1 Input Capture Flag 1.

0: No input capture (reset value).

1: An input capture has occurred on the ICAP1 pin or the counter has reached the OC2R value in PWM mode. To clear this bit, first read the SR register, then read or write the low byte of the IC1R (IC1LR) register.

#### Bit 6 = OCF1 Output Compare Flag 1.

0: No match (reset value).

1: The content of the free running counter has matched the content of the OC1R register. To clear this bit, first read the SR register, then read or write the low byte of the OC1R (OC1LR) register.

Bit 5 = **TOF** *Timer Overflow Flag.* 

0: No timer overflow (reset value).

1: The free running counter rolled over from FFFFh to 0000h. To clear this bit, first read the SR register, then read or write the low byte of the CR (CLR) register. **Note:** Reading or writing the ACLR register does not clear TOF.

#### Bit 4 = ICF2 Input Capture Flag 2.

- 0: No input capture (reset value).
- 1: An input capture has occurred on the ICAP2 pin. To clear this bit, first read the SR register, then read or write the low byte of the IC2R (IC2LR) register.

#### Bit 3 = **OCF2** *Output Compare Flag 2.*

- 0: No match (reset value).
- 1: The content of the free running counter has matched the content of the OC2R register. To clear this bit, first read the SR register, then read or write the low byte of the OC2R (OC2LR) register.

#### Bit 2 = **TIMD** *Timer disable.*

This bit is set and cleared by software. When set, it freezes the timer prescaler and counter and disabled the output functions (OCMP1 and OCMP2 pins) to reduce power consumption. Access to the timer registers is still available, allowing the timer configuration to be changed, or the counter reset, while it is disabled.

0: Timer enabled

1: Timer prescaler, counter and outputs disabled

Bits 1:0 = Reserved, must be kept cleared.

## **INPUT CAPTURE 1 HIGH REGISTER (IC1HR)**

Read Only Reset Value: Undefined

This is an 8-bit read only register that contains the high part of the counter value (transferred by the input capture 1 event).

7				0	
MSB				LSB	

## **INPUT CAPTURE 1 LOW REGISTER (IC1LR)**

#### Read Only

Reset Value: Undefined

This is an 8-bit read only register that contains the low part of the counter value (transferred by the input capture 1 event).

7				0	
MSB				LSB	

#### OUTPUT COMPARE 1 HIGH REGISTER (OC1HR)

Read/Write

Reset Value: 1000 0000 (80h)

This is an 8-bit register that contains the high part of the value to be compared to the CHR register.

7				0	
MSB				LSB	

#### OUTPUT COMPARE 1 LOW REGISTER (OC1LR)

#### Read/Write

Reset Value: 0000 0000 (00h)

This is an 8-bit register that contains the low part of the value to be compared to the CLR register.

7				0	
MSB				LSB	

## OUTPUT COMPARE 2 HIGH REGISTER (OC2HR)

Read/Write

Reset Value: 1000 0000 (80h)

This is an 8-bit register that contains the high part of the value to be compared to the CHR register.

7				0	
MSB				LSB	

## OUTPUT COMPARE 2 LOW REGISTER (OC2LR)

Read/Write

Reset Value: 0000 0000 (00h)

This is an 8-bit register that contains the low part of the value to be compared to the CLR register.

7				0
MSB				LSB

## **COUNTER HIGH REGISTER (CHR)**

#### Read Only

Reset Value: 1111 1111 (FFh)

This is an 8-bit register that contains the high part of the counter value.

7				0
MSB				LSB

## **COUNTER LOW REGISTER (CLR)**

Read Only

5/

Reset Value: 1111 1100 (FCh)

This is an 8-bit register that contains the low part of the counter value. A write to this register resets the counter. An access to this register after accessing the CSR register clears the TOF bit.

7				0
MSB				LSB

## ALTERNATE COUNTER HIGH REGISTER (ACHR)

Read Only

Reset Value: 1111 1111 (FFh)

This is an 8-bit register that contains the high part of the counter value.

7				0	
MSB				LSB	

# ALTERNATE COUNTER LOW REGISTER (ACLR)

#### Read Only

Reset Value: 1111 1100 (FCh)

This is an 8-bit register that contains the low part of the counter value. A write to this register resets the counter. An access to this register after an access to CSR register does not clear the TOF bit in the CSR register.

7				0
MSB				LSB

## **INPUT CAPTURE 2 HIGH REGISTER (IC2HR)**

Read Only

Reset Value: Undefined

This is an 8-bit read only register that contains the high part of the counter value (transferred by the Input Capture 2 event).

7				0
MSB				LSB

#### **INPUT CAPTURE 2 LOW REGISTER (IC2LR)**

Read Only Reset Value: Undefined

This is an 8-bit read only register that contains the low part of the counter value (transferred by the Input Capture 2 event).

7				0
MSB				LSB

## Table 18. 16-Bit Timer Register Map

Address (Hex.)	Register Name	7	6	5	4	3	2	1	0

## 10.5 8-BIT TIMER (TIM8)

#### 10.5.1 Introduction

The timer consists of a 8-bit free-running counter driven by a programmable prescaler.

It may be used for a variety of purposes, including pulse length measurement of up to two input signals (*input capture*) or generation of up to two output waveforms (*output compare* and *PWM*).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the clock prescaler.

#### 10.5.2 Main Features

- Programmable prescaler: f<sub>CPU</sub> divided by 2, 4, 8 or f<sub>OSC2</sub> divided by 8000.
- Overflow status flag and maskable interrupt
- Output compare functions with
  - 2 dedicated 8-bit registers
  - 2 dedicated programmable signals
  - 2 dedicated status flags
  - 1 dedicated maskable interrupt
- Input capture functions with
  - 2 dedicated 8-bit registers
  - 2 dedicated active edge selection signals
  - 2 dedicated status flags
  - 1 dedicated maskable interrupt
- Pulse width modulation mode (PWM)
- One pulse mode

5/

- Reduced Power Mode
- 4 alternate functions on I/O ports (ICAP1, ICAP2, OCMP1, OCMP2)\*

The Block Diagram is shown in Figure 1.

\*Note: Some timer pins may not be available (not bonded) in some ST7 devices. Refer to the device pin out description.

When reading an input signal on a non-bonded pin, the value will always be '1'.

#### **10.5.3 Functional Description**

#### 10.5.3.1 Counter

The main block of the Programmable Timer is a 8bit free running upcounter and its associated 8-bit registers.

These two read-only 8-bit registers contain the same value but with the difference that reading the ACTR register does not clear the TOF bit (Timer overflow flag), located in the Status register, (SR).

Writing in the CTR register or ACTR register resets the free running counter to the FCh value.

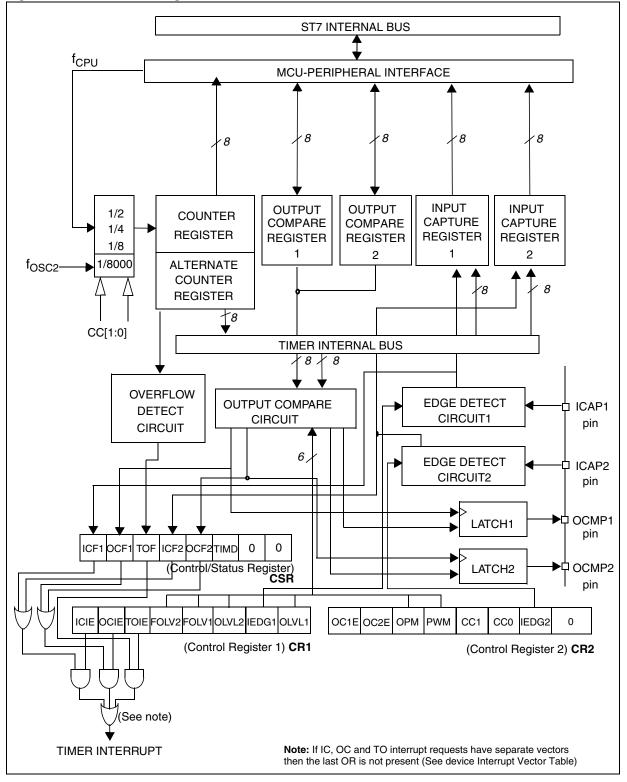

Both counters have a reset value of FCh (this is the only value which is reloaded in the 8-bit timer). The reset value of both counters is also FCh in One Pulse mode and PWM mode.

The timer clock depends on the clock control bits of the CR2 register, as shown in Table 1. The value in the counter register repeats every 512, 1024, 2048 or 20480000  $f_{CPU}$  clock cycles depending on the CC[1:0] bits.

The timer frequency can be  $f_{CPU}/2$ ,  $f_{CPU}/4$ ,  $f_{CPU}/8$  or  $f_{OSC2}/8000$ .

For example, if  $f_{OSC2}$ /8000 is selected, and  $f_{OSC2} = 8$  MHz, the timer frequency will be 1 ms. Refer to Table 1 on page 16.

## Figure 59. Timer Block Diagram

Δ7/

57

Whatever the timer mode used (input capture, output compare, one pulse mode or PWM mode) an overflow occurs when the counter rolls over from FFh to 00h then:

- The TOF bit of the SR register is set.
- A timer interrupt is generated if:
  - TOIE bit of the CR1 register is set and
  - I bit of the CC register is cleared.

If one of these conditions is false, the interrupt remains pending to be issued as soon as they are both true.

Clearing the overflow interrupt request is done in two steps:

1. Reading the SR register while the TOF bit is set.

2. An access (read or write) to the CTR register.

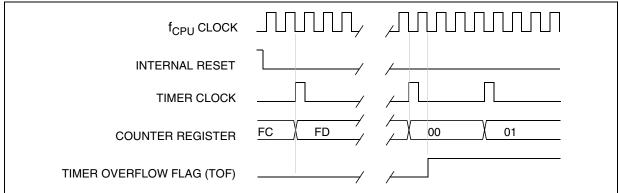

**Notes:** The TOF bit is not cleared by accesses to ACTR register. The advantage of accessing the ACTR register rather than the CTR register is that it allows simultaneous use of the overflow function and reading the free running counter at random times (for example, to measure elapsed time) without the risk of clearing the TOF bit erroneously.

The timer is not affected by WAIT mode.

In HALT mode, the counter stops counting until the mode is exited. Counting then resumes from the previous count (MCU awakened by an interrupt) or from the reset count (MCU awakened by a Reset).

Note: The MCU is in reset state when the internal reset signal is high, when it is low the MCU is running.

#### 10.5.3.2 Input Capture

In this section, the index, *i*, may be 1 or 2 because there are two input capture functions in the 8-bit timer.

The two 8-bit input capture registers (IC1R and IC2R) are used to latch the value of the free running counter after a transition is detected on the ICAP*i* pin (see Figure 5).

IC*i*R register is a read-only register.

The active transition is software programmable through the IEDG*i* bit of Control Registers (CR*i*).

Timing resolution is one count of the free running counter (see Table 1).

#### **Procedure:**

To use the input capture function select the following in the CR2 register:

- Select the timer clock (CC[1:0]) (see Table 1).
- Select the edge of the active transition on the ICAP2 pin with the IEDG2 bit (the ICAP2 pin must be configured as floating input or input with pull-up without interrupt if this configuration is available).

And select the following in the CR1 register:

- Set the ICIE bit to generate an interrupt after an input capture coming from either the ICAP1 pin or the ICAP2 pin
- Select the edge of the active transition on the ICAP1 pin with the IEDG1 bit (the ICAP1 pin must be configured as floating input or input with pull-up without interrupt if this configuration is available).

When an input capture occurs:

- ICF*i* bit is set.
- The IC*i*R register contains the value of the free running counter on the active transition on the ICAP*i* pin (see Figure 6).
- A timer interrupt is generated if the ICIE bit is set and the interrupt mask is cleared in the CC register. Otherwise, the interrupt remains pending until both conditions become true.

Clearing the Input Capture interrupt request (that is, clearing the ICF*i* bit) is done in two steps:

1. Reading the SR register while the ICF*i* bit is set.

2. An access (read or write) to the ICiR register.

#### Notes:

1. The IC*i*R register contains the free running counter value which corresponds to the most recent input capture.

2. The two input capture functions can be used together even if the timer also uses the two output compare functions.

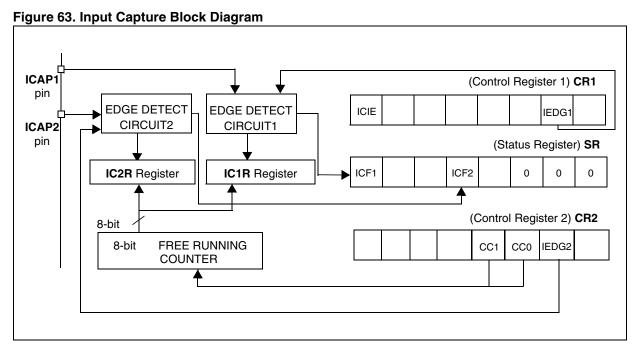

3. Once the ICIE bit is set both input capture features may trigger interrupt requests. If only one is needed in the application, the interrupt routine software needs to discard the unwanted capture interrupt. This can be done by checking the ICF1 and ICF2 flags and resetting them both.

4. In One pulse Mode and PWM mode only Input Capture 2 can be used.

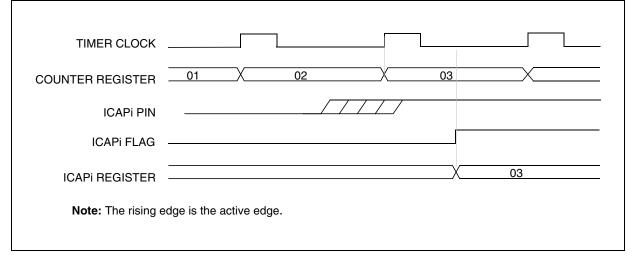

5. The alternate inputs (ICAP1 and ICAP2) are always directly connected to the timer. So any transitions on these pins activates the input capture function.

Moreover if one of the ICAP*i* pins is configured as an input and the second one as an output, an interrupt can be generated if the user toggles the output pin and if the ICIE bit is set.

6. The TOF bit can be used with interrupt generation in order to measure events that go beyond the timer range (FFh).

## Figure 64. Input Capture Timing Diagram

#### 10.5.3.3 Output Compare

In this section, the index, *i*, may be 1 or 2 because there are two output compare functions in the 8-bit timer.

This function can be used to control an output waveform or indicate when a period of time has elapsed.

When a match is found between the Output Compare register and the free running counter, the output compare function:

- Assigns pins with a programmable value if the OC/E bit is set
- Sets a flag in the status register
- Generates an interrupt if enabled

Two 8-bit registers Output Compare Register 1 (OC1R) and Output Compare Register 2 (OC2R) contain the value to be compared to the counter register each timer clock cycle.

These registers are readable and writable and are not affected by the timer hardware. A reset event changes the OC*i*R value to 00h.

Timing resolution is one count of the free running counter:  $(f_{CPU/CC[1:0]})$ .

#### **Procedure:**

To use the output compare function, select the following in the CR2 register:

- Set the OC*i*E bit if an output is needed then the OCMP*i* pin is dedicated to the output compare *i* signal.
- Select the timer clock (CC[1:0]) (see Table 1).

And select the following in the CR1 register:

- Select the OLVL*i* bit to applied to the OCMP*i* pins after the match occurs.
- Set the OCIE bit to generate an interrupt if it is needed.

When a match is found between OCRi register and CR register:

- OCFi bit is set.
- The OCMP*i* pin takes OLVL*i* bit value (OCMP*i* pin latch is forced low during reset).
- A timer interrupt is generated if the OCIE bit is set in the CR1 register and the I bit is cleared in the CC register (CC).

The OC*i*R register value required for a specific timing application can be calculated using the following formula:

$$\Delta \operatorname{OC} i R = \frac{\Delta t * f_{CPU}}{PRESC}$$

Where:

 $\Delta t$  = Output compare period (in seconds)

 $f_{CPU}$  = PLL output x2 clock frequency in hertz (or  $f_{OSC}/2$  if PLL is not enabled)

PRESC = Timer prescaler factor (2, 4, 8 or 8000 depending on CC[1:0] bits, see Table 1)

Clearing the output compare interrupt request (that is, clearing the OCF*i* bit) is done by:

- 1. Reading the SR register while the OCF*i* bit is set.
- 2. An access (read or write) to the OC*i*R register.

#### Notes:

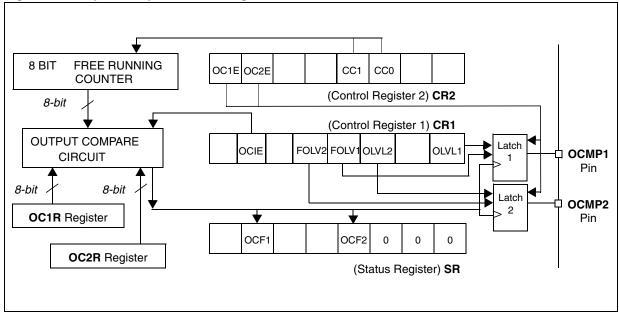

- 1. Once the OCIE bit is set both output compare features may trigger interrupt requests. If only one is needed in the application, the interrupt routine software needs to discard the unwanted compare interrupt. This can be done by checking the OCF1 and OCF2 flags and resetting them both.
- 2. If the OC*i*E bit is not set, the OCMP*i* pin is a general I/O port and the OLVL*i* bit will not appear when a match is found but an interrupt could be generated if the OCIE bit is set.
- 3. When the timer clock is f<sub>CPU</sub>/2, OCF*i* and OCMP*i* are set while the counter value equals the OC*i*R register value (see Figure 8). This behaviour is the same in OPM or PWM mode. When the timer clock is f<sub>CPU</sub>/4, f<sub>CPU</sub>/8 or f<sub>CPU</sub>/8000, OCF*i* and OCMP*i* are set while the counter value equals the OC*i*R register value plus 1 (see Figure 9).
- 4. The output compare functions can be used both for generating external events on the OCMP*i* pins even if the input capture mode is also used.
- 5. The value in the 8-bit OC*i*R register and the OLV*i* bit should be changed after each successful comparison in order to control an output

iests. If only Forced Compare Output capability

When the FOLV*i* bit is set by software, the OLVL*i* bit is copied to the OCMP*i* pin. The OLV*i* bit has to be toggled in order to toggle the OCMP*i* pin when it is enabled (OC*i*E bit = 1). The OCF*i* bit is then not set by hardware, and thus no interrupt request is generated.

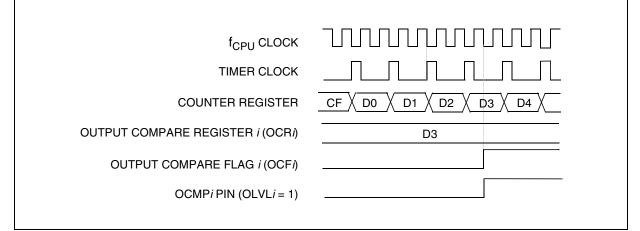

waveform or establish a new elapsed timeout.

The FOLVL*i* bits have no effect in both one pulse mode and PWM mode.

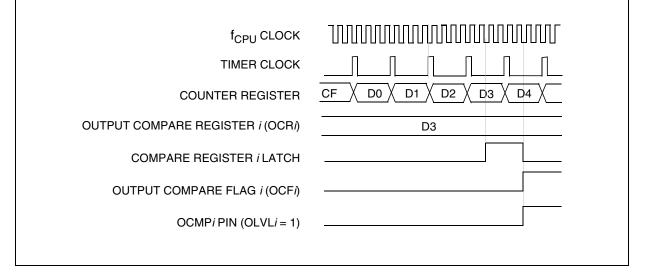

#### Figure 65. Output Compare Block Diagram

## Figure 66. Output Compare Timing Diagram, f<sub>TIMER</sub> = f<sub>CPU</sub>/2

## Figure 67. Output Compare Timing Diagram, $f_{TIMER} = f_{CPU}/4$

#### 10.5.3.4 One Pulse Mode

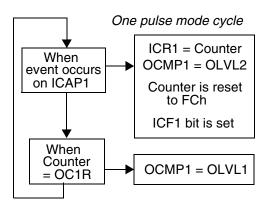

One Pulse mode enables the generation of a pulse when an external event occurs. This mode is selected via the OPM bit in the CR2 register.

The one pulse mode uses the Input Capture1 function and the Output Compare1 function.

#### Procedure:

To use one pulse mode:

- 1. Load the OC1R register with the value corresponding to the length of the pulse (see the formula in the opposite column).
- 2. Select the following in the CR1 register:
  - Using the OLVL1 bit, select the level to be applied to the OCMP1 pin after the pulse.
  - Using the OLVL2 bit, select the level to be applied to the OCMP1 pin during the pulse.
  - Select the edge of the active transition on the ICAP1 pin with the IEDG1 bit (the ICAP1 pin must be configured as floating input).
- 3. Select the following in the CR2 register:
  - Set the OC1E bit, the OCMP1 pin is then dedicated to the Output Compare 1 function.
  - Set the OPM bit.
  - Select the timer clock CC[1:0] (see Table 1).

Then, on a valid event on the ICAP1 pin, the counter is initialized to FCh and OLVL2 bit is loaded on the OCMP1 pin, the ICF1 bit is set and the value FFFDh is loaded in the IC1R register.

Because the ICF1 bit is set when an active edge occurs, an interrupt can be generated if the ICIE bit is set.

Clearing the Input Capture interrupt request (that is, clearing the ICF*i* bit) is done in two steps:

1. Reading the SR register while the ICF*i* bit is set.

2. An access (read or write) to the ICiLR register.

The OC1R register value required for a specific timing application can be calculated using the following formula:

Where:

t = Pulse period (in seconds)

- $f_{CPU}$  = PLL output x2 clock frequency in hertz (or  $f_{OSC}/2$  if PLL is not enabled)
- PRESC = Timer prescaler factor (2, 4, 8 or 8000 depending on the CC[1:0] bits, see Table 1)

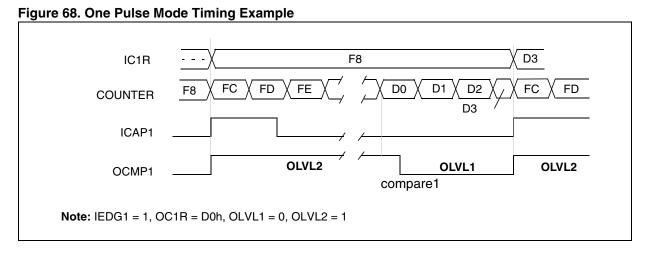

When the value of the counter is equal to the value of the contents of the OC1R register, the OLVL1 bit is output on the OCMP1 pin, (See Figure 10).

#### Notes:

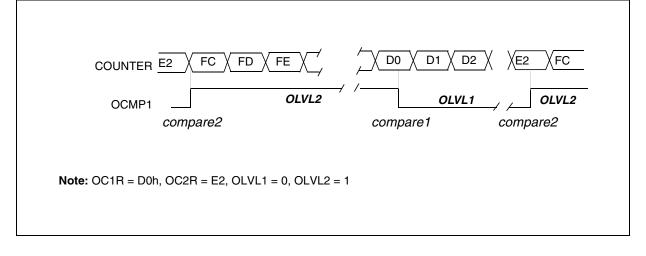

- 1. The OCF1 bit cannot be set by hardware in one pulse mode but the OCF2 bit can generate an Output Compare interrupt.
- 2. When the Pulse Width Modulation (PWM) and One Pulse Mode (OPM) bits are both set, the PWM mode is the only active one.
- 3. If OLVL1=OLVL2 a continuous signal will be seen on the OCMP1 pin.
- 4. The ICAP1 pin can not be used to perform input capture. The ICAP2 pin can be used to perform input capture (ICF2 can be set and IC2R can be loaded) but the user must take care that the counter is reset each time a valid edge occurs on the ICAP1 pin and ICF1 can also generates interrupt if ICIE is set.
- 5. When one pulse mode is used OC1R is dedicated to this mode. Nevertheless OC2R and OCF2 can be used to indicate a period of time has been elapsed but cannot generate an output waveform because the level OLVL2 is dedicated to the one pulse mode.

57/

## Figure 69. Pulse Width Modulation Mode Timing Example

#### 10.5.3.5 Pulse Width Modulation Mode

Pulse Width Modulation (PWM) mode enables the generation of a signal with a frequency and pulse length determined by the value of the OC1R and OC2R registers.

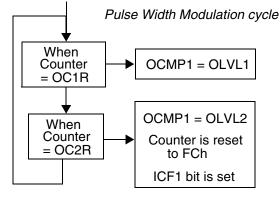

Pulse Width Modulation mode uses the complete Output Compare 1 function plus the OC2R register, and so this functionality can not be used when PWM mode is activated.

In PWM mode, double buffering is implemented on the output compare registers. Any new values written in the OC1R and OC2R registers are taken into account only at the end of the PWM period (OC2) to avoid spikes on the PWM output pin (OCMP1).

#### Procedure

To use pulse width modulation mode:

- 1. Load the OC2R register with the value corresponding to the period of the signal using the formula in the opposite column.
- 2. Load the OC1R register with the value corresponding to the period of the pulse if (OLVL1 = 0 and OLVL2 = 1) using the formula in the opposite column.
- 3. Select the following in the CR1 register:
  - Using the OLVL1 bit, select the level to be applied to the OCMP1 pin after a successful comparison with the OC1R register.
  - Using the OLVL2 bit, select the level to be applied to the OCMP1 pin after a successful comparison with the OC2R register.
- 4. Select the following in the CR2 register:
  - Set OC1E bit: the OCMP1 pin is then dedicated to the output compare 1 function.
  - Set the PWM bit.
  - Select the timer clock (CC[1:0]) (see Table 1).

If OLVL1 = 1 and OLVL2 = 0 the length of the positive pulse is the difference between the OC2R and OC1R registers.

If OLVL1 = OLVL2 a continuous signal will be seen on the OCMP1 pin.

The OC*i*R register value required for a specific timing application can be calculated using the following formula:

$$OCiR Value = \frac{t \cdot f_{CPU}}{PRESC} - 5$$

Where:

t = Signal or pulse period (in seconds)

- $f_{CPU}$  = PLL output x2 clock frequency in hertz (or  $f_{OSC}/2$  if PLL is not enabled)
- PRESC = Timer prescaler factor (2, 4, 8 or 8000 depending on CC[1:0] bits, see Table 1)

The Output Compare 2 event causes the counter to be initialized to FCh (See Figure 11)

#### Notes:

- 1. The OCF1 and OCF2 bits cannot be set by hardware in PWM mode therefore the Output Compare interrupt is inhibited.
- The ICF1 bit is set by hardware when the counter reaches the OC2R value and can produce a timer interrupt if the ICIE bit is set and the I bit is cleared.
- 3. In PWM mode the ICAP1 pin can not be used to perform input capture because it is disconnected to the timer. The ICAP2 pin can be used to perform input capture (ICF2 can be set and IC2R can be loaded) but the user must take care that the counter is reset each period and ICF1 can also generates interrupt if ICIE is set.
- 4. When the Pulse Width Modulation (PWM) and One Pulse Mode (OPM) bits are both set, the PWM mode is the only active one.

## 10.5.4 Low Power Modes

Mode	Description
WAIT	No effect on 8-bit Timer. Timer interrupts cause the device to exit from WAIT mode.
	8-bit Timer registers are frozen.
HALT	In HALT mode, the counter stops counting until Halt mode is exited. Counting resumes from the previous count when the MCU is woken up by an interrupt with "exit from HALT mode" capability or from the counter reset value when the MCU is woken up by a RESET.
	If an input capture event occurs on the ICAP <i>i</i> pin, the input capture detection circuitry is armed. Consequently, when the MCU is woken up by an interrupt with "exit from HALT mode" capability, the ICF <i>i</i> bit is set, and the counter value present when exiting from HALT mode is captured into the IC <i>I</i> R register.

#### 10.5.5 Interrupts

<u>(۲</u>/

Interrupt Event	Event Flag	Enable Control Bit	Exit from Wait	Exit from Halt
Input Capture 1 event/Counter reset in PWM mode	ICF1	ICIE		
Input Capture 2 event	ICF2	ICIL		
Output Compare 1 event (not available in PWM mode)	OCF1	OCIE	Yes	No
Output Compare 2 event (not available in PWM mode)	OCF2	OCIE		
Timer Overflow event	TOF	TOIE		

**Note:** The 8-bit Timer interrupt events are connected to the same interrupt vector (see Interrupts chapter). These events generate an interrupt if the corresponding Enable Control Bit is set and the interrupt mask in the CC register is reset (RIM instruction).

## 10.5.6 Summary of Timer modes

MODES	AVAILABLE RESOURCES					
MODES	Input Capture 1	Input Capture 2	Output Compare 1	Output Compare 2		
Input Capture (1 and/or 2)	Yes	Yes	Yes	Yes		
Output Compare (1 and/or 2)	165	165	165	165		
One Pulse Mode	No	Not Recommended <sup>1)</sup>	No	Partially <sup>2)</sup>		
PWM Mode		Not Recommended <sup>3)</sup>	NO	No		

1) See note 4 in "One Pulse Mode" on page 11

2) See note 5 in "One Pulse Mode" on page 11

3) See note 4 in "Pulse Width Modulation Mode" on page 13

#### **10.5.7 Register Description**

Each Timer is associated with three control and status registers, and with six data registers (8-bit values) relating to the two input captures, the two output compares, the counter and the alternate counter.

#### **CONTROL REGISTER 1 (CR1)**

#### Read/Write

Reset Value: 0000 0000 (00h)

7							0
ICIE	OCIE	TOIE	FOLV2	FOLV1	OLVL2	IEDG1	OLVL1

Bit 7 = ICIE Input Capture Interrupt Enable.

- 0: Interrupt is inhibited.
- 1: A timer interrupt is generated whenever the ICF1 or ICF2 bit of the SR register is set.

Bit 6 = **OCIE** *Output Compare Interrupt Enable.* 0: Interrupt is inhibited.

1: A timer interrupt is generated whenever the OCF1 or OCF2 bit of the SR register is set.

Bit 5 = **TOIE** *Timer Overflow Interrupt Enable.* 

0: Interrupt is inhibited.

1: A timer interrupt is enabled whenever the TOF bit of the SR register is set.

#### Bit 4 = FOLV2 Forced Output Compare 2.

This bit is set and cleared by software.

- 0: No effect on the OCMP2 pin.
- 1: Forces the OLVL2 bit to be copied to the OCMP2 pin, if the OC2E bit is set and even if there is no successful comparison.

#### Bit 3 = FOLV1 Forced Output Compare 1.

This bit is set and cleared by software.

- 0: No effect on the OCMP1 pin.
- 1: Forces OLVL1 to be copied to the OCMP1 pin, if the OC1E bit is set and even if there is no successful comparison.

#### Bit 2 = OLVL2 Output Level 2.

This bit is copied to the OCMP2 pin whenever a successful comparison occurs with the OC2R register and OCxE is set in the CR2 register. This value is copied to the OCMP1 pin in One Pulse Mode and Pulse Width Modulation mode.

#### Bit 1 = IEDG1 Input Edge 1.

This bit determines which type of level transition on the ICAP1 pin will trigger the capture.

0: A falling edge triggers the capture.

1: A rising edge triggers the capture.

#### Bit 0 = **OLVL1** *Output Level 1.*

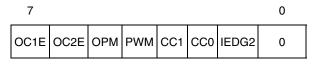

The OLVL1 bit is copied to the OCMP1 pin whenever a successful comparison occurs with the OC1R register and the OC1E bit is set in the CR2 register.

## 8-BIT TIMER (Cont'd) CONTROL REGISTER 2 (CR2)

Read/Write

Reset Value: 0000 0000 (00h)

## Bit 7 = **OC1E** *Output Compare 1 Pin Enable.*

This bit is used only to output the signal from the timer on the OCMP1 pin (OLV1 in Output Compare mode, both OLV1 and OLV2 in PWM and one-pulse mode). Whatever the value of the OC1E bit, the Output Compare 1 function of the timer remains active.

- 0: OCMP1 pin alternate function disabled (I/O pin free for general-purpose I/O).
- 1: OCMP1 pin alternate function enabled.

#### Bit 6 = **OC2E** Output Compare 2 Pin Enable.

This bit is used only to output the signal from the timer on the OCMP2 pin (OLV2 in Output Compare mode). Whatever the value of the OC2E bit, the Output Compare 2 function of the timer remains active.

- 0: OCMP2 pin alternate function disabled (I/O pin free for general-purpose I/O).
- 1: OCMP2 pin alternate function enabled.

#### Bit 5 = OPM One Pulse Mode.

- 0: One Pulse Mode is not active.
- 1: One Pulse Mode is active, the ICAP1 pin can be used to trigger one pulse on the OCMP1 pin; the active transition is given by the IEDG1 bit. The length of the generated pulse depends on the contents of the OC1R register.

## Bit 4 = **PWM** Pulse Width Modulation.

- 0: PWM mode is not active.
- 1: PWM mode is active, the OCMP1 pin outputs a programmable cyclic signal; the length of the pulse depends on the value of OC1R register; the period depends on the value of OC2R register.

#### Bit 3, 2 = CC[1:0] Clock Control.

The timer clock mode depends on these bits:

#### Table 19. Clock Control Bits

Timer Clock	CC1	CC0
f <sub>CPU</sub> / 4	0	0
f <sub>CPU</sub> / 2	0	1
f <sub>CPU</sub> / 8	1	0
f <sub>OSC2</sub> / 8000*	1	1

\* Not available in Slow mode in ST72F561.

#### Bit 1 = IEDG2 Input Edge 2.

This bit determines which type of level transition on the ICAP2 pin will trigger the capture.

0: A falling edge triggers the capture.

1: A rising edge triggers the capture.

Bit 0 = Reserved, must be kept at 0.

## 8-BIT TIMER (Cont'd) CONTROL/STATUS REGISTER (CSR)

Read Only (except bit 2 R/W) Reset Value: 0000 0000 (00h)

7							0
ICF1	OCF1	TOF	ICF2	OCF2	TIMD	0	0

Bit 7 = ICF1 Input Capture Flag 1.

0: No input capture (reset value).

1: An input capture has occurred on the ICAP1 pin or the counter has reached the OC2R value in PWM mode. To clear this bit, first read the SR register, then read or write the the IC1R register.

#### Bit 6 = OCF1 Output Compare Flag 1.

0: No match (reset value).

1: The content of the free running counter has matched the content of the OC1R register. To clear this bit, first read the SR register, then read or write the OC1R register.

#### Bit 5 = **TOF** *Timer Overflow Flag.*

0: No timer overflow (reset value).

1: The free running counter rolled over from FFh to 00h. To clear this bit, first read the SR register, then read or write the CTR register. **Note:** Reading or writing the ACTR register does not clear TOF.

#### Bit 4 = ICF2 Input Capture Flag 2.

- 0: No input capture (reset value).
- 1: An input capture has occurred on the ICAP2 pin. To clear this bit, first read the SR register, then read or write the IC2R register.

#### Bit 3 = OCF2 Output Compare Flag 2.

- 0: No match (reset value).
- 1: The content of the free running counter has matched the content of the OC2R register. To clear this bit, first read the SR register, then read or write the OC2R register.

#### Bit 2 = **TIMD** *Timer disable.*

This bit is set and cleared by software. When set, it freezes the timer prescaler and counter and disabled the output functions (OCMP1 and OCMP2 pins) to reduce power consumption. Access to the timer registers is still available, allowing the timer configuration to be changed, or the counter reset, while it is disabled.

#### 0: Timer enabled

1: Timer prescaler, counter and outputs disabled

Bits 1:0 = Reserved, must be kept cleared.

## 8-BIT TIMER (Cont'd) INPUT CAPTURE 1 REGISTER (IC1R)

Read Only

Reset Value: Undefined

This is an 8-bit read only register that contains the counter value (transferred by the input capture 1 event).

7				0	
MSB				LSB	

## **OUTPUT COMPARE 1 REGISTER (OC1R)**

#### Read/Write

Reset Value: 0000 0000 (00h)

This is an 8-bit register that contains the value to be compared to the CTR register.

7				0
MSB				LSB

## **OUTPUT COMPARE 2 REGISTER (OC2R)**

Read/Write

Reset Value: 0000 0000 (00h)

This is an 8-bit register that contains the value to be compared to the CTR register.

'
---

5/

0

MSB				LSB

## **COUNTER REGISTER (CTR)**

#### Read Only

Reset Value: 1111 1100 (FCh)

This is an 8-bit register that contains the counter value. A write to this register resets the counter. An access to this register after accessing the CSR register clears the TOF bit.

7				0	
MSB				LSB	

## ALTERNATE COUNTER REGISTER (ACTR)

#### Read Only

Reset Value: 1111 1100 (FCh)

This is an 8-bit register that contains the counter value. A write to this register resets the counter. An access to this register after an access to CSR register does not clear the TOF bit in the CSR register.

7				0
MSB				LSB

#### **INPUT CAPTURE 2 REGISTER (IC2R)**

Read Only

Reset Value: Undefined

This is an 8-bit read only register that contains the counter value (transferred by the Input Capture 2 event).

7				0	
MSB				LSB

## **ON-CHIP PERIPHERALS** (cont'd)

#### **10.6 SERIAL PERIPHERAL INTERFACE (SPI)**

#### 10.6.1 Introduction

The Serial Peripheral Interface (SPI) allows fullduplex, synchronous, serial communication with external devices. An SPI system may consist of a master and one or more slaves or a system in which devices may be either masters or slaves.

#### 10.6.2 Main Features

- Full duplex synchronous transfers (on three lines)
- Simplex synchronous transfers (on two lines)
- Master or slave operation
- 6 master mode frequencies (f<sub>CPU</sub>/4 max.)
- f<sub>CPU</sub>/2 max. slave mode frequency (see note)
- SS Management by software or hardware
- Programmable clock polarity and phase
- End of transfer interrupt flag
- Write collision, Master Mode Fault and Overrun flags

**Note:** In slave mode, continuous transmission is not possible at maximum frequency due to the software overhead for clearing status flags and to initiate the next transmission sequence.

#### **10.6.3 General Description**

Figure 1 on page 3 shows the serial peripheral interface (SPI) block diagram. There are three registers:

- SPI Control Register (SPICR)
- SPI Control/Status Register (SPICSR)
- SPI Data Register (SPIDR)

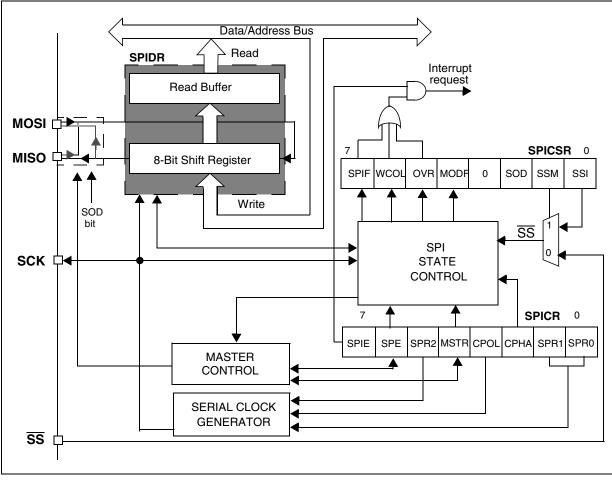

The SPI is connected to external devices through four pins:

- MISO: Master In / Slave Out data
- MOSI: Master Out / Slave In data
- SCK: Serial Clock out by SPI masters and input by SPI slaves
- SS: Slave select:

This input signal acts as a 'chip select' to let the SPI master communicate with slaves individually and to avoid contention on the data lines. Slave SS inputs can be driven by standard I/O ports on the master Device.

## SERIAL PERIPHERAL INTERFACE (SPI) (cont'd)

لرکا

#### 10.6.3.1 Functional Description

57/

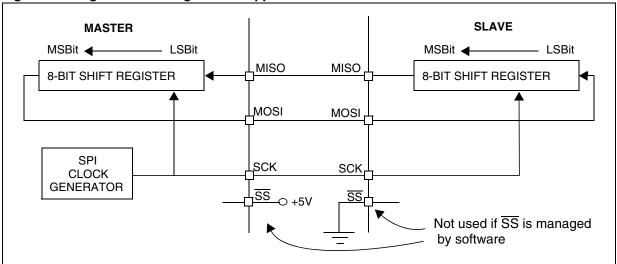

A basic example of interconnections between a single master and a single slave is illustrated in Figure 2.

The MOSI pins are connected together and the MISO pins are connected together. In this way data is transferred serially between master and slave (most significant bit first).

The communication is always initiated by the master. When the master device transmits data to a slave device via MOSI pin, the slave device responds by sending data to the master device via the MISO pin. This implies full duplex communication with both data out and data in synchronized with the same clock signal (which is provided by the master device via the SCK pin).

To use a single data line, the MISO and MOSI pins must be connected at each node (in this case only simplex communication is possible).

Four possible data/clock timing relationships may be chosen (see Figure 5 on page 7) but master and slave must be programmed with the same timing mode.

#### Figure 71. Single Master/ Single Slave Application

### 10.6.3.2 Slave Select Management

As an alternative to using the  $\overline{SS}$  pin to control the Slave Select signal, the application can choose to manage the Slave Select signal by software. This is configured by the SSM bit in the SPICSR register (see Figure 4).

In software management, the external  $\overline{SS}$  pin is free for other application uses and the internal  $\overline{SS}$ signal level is driven by writing to the SSI bit in the SPICSR register.

#### In Master mode:

- SS internal must be held high continuously

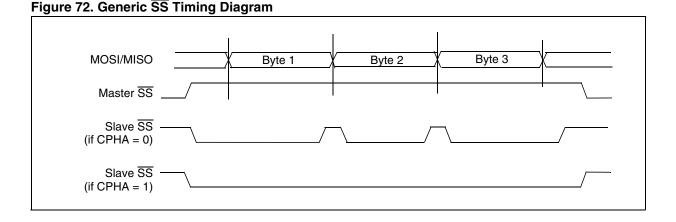

#### In Slave Mode:

There are two cases depending on the data/clock timing relationship (see Figure 3):

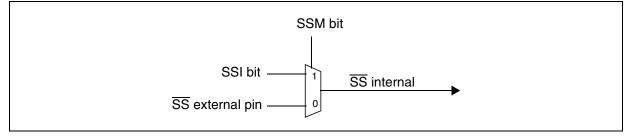

- If CPHA = 1 (data latched on second clock edge):
  - $\overline{SS}$  internal must be held low during the entire transmission. This implies that in single slave applications the SS pin either can be tied to V<sub>SS</sub>, or made free for standard I/O by managing the SS function by software (SSM = 1 and SSI = 0 in the in the SPICSR register)

If CPHA = 0 (data latched on first clock edge):

 $-\overline{SS}$  internal must be held low during byte transmission and pulled high between each byte to allow the slave to write to the shift register. If SS is not pulled high, a Write Collision error will occur when the slave writes to the shift register (see Section 0.1.5.3).

#### Figure 73. Hardware/Software Slave Select Management

#### 10.6.3.3 Master Mode Operation

In master mode, the serial clock is output on the SCK pin. The clock frequency, polarity and phase are configured by software (refer to the description of the SPICSR register).

**Note:** The idle state of SCK must correspond to the polarity selected in the SPICSR register (by pulling up SCK if CPOL = 1 or pulling down SCK if CPOL = 0).

#### How to operate the SPI in master mode

To operate the SPI in master mode, perform the following steps in order:

- 1. Write to the SPICR register:
  - Select the clock frequency by configuring the SPR[2:0] bits.
  - Select the clock polarity and clock phase by configuring the CPOL and CPHA bits. Figure 5 shows the four possible configurations.
     Note: The slave must have the same CPOL and CPHA settings as the master.
- 2. Write to the SPICSR register:
  - Either set the SSM bit and set the SSI bit or clear the SSM bit and tie the SS pin high for the complete byte transmit sequence.
- 3. Write to the SPICR register:
  - Set the MSTR and SPE bits
     <u>Note</u>: MSTR and SPE bits remain set only if SS is high).

**Important note:** if the SPICSR register is not written first, the SPICR register setting (MSTR bit) may be not taken into account.

The transmit sequence begins when software writes a byte in the SPIDR register.

#### 10.6.3.4 Master Mode Transmit Sequence

When software writes to the SPIDR register, the data byte is loaded into the 8-bit shift register and then shifted out serially to the MOSI pin most significant bit first.

When data transfer is complete:

- The SPIF bit is set by hardware.
- An interrupt request is generated if the SPIE bit is set and the interrupt mask in the CCR register is cleared.

Clearing the SPIF bit is performed by the following software sequence:

- 1. An access to the SPICSR register while the SPIF bit is set
- 2. A read to the SPIDR register

**Note:** While the SPIF bit is set, all writes to the SPIDR register are inhibited until the SPICSR register is read.

#### 10.6.3.5 Slave Mode Operation

In slave mode, the serial clock is received on the SCK pin from the master device.

To operate the SPI in slave mode:

- 1. Write to the SPICSR register to perform the following actions:
  - Select the clock polarity and clock phase by configuring the CPOL and CPHA bits (see Figure 5).
     Note: The slave must have the same CPOL and CPHA settings as the master.
  - Manage the  $\overline{SS}$  pin as described in Section 0.1.3.2 and Figure 3. If CPHA = 1  $\overline{SS}$  must be held low continuously. If CPHA = 0  $\overline{SS}$  must be held low during byte transmission and pulled up between each byte to let the slave write in the shift register.
- 2. Write to the SPICR register to clear the MSTR bit and set the SPE bit to enable the SPI I/O functions.

#### 10.6.3.6 Slave Mode Transmit Sequence

When software writes to the SPIDR register, the data byte is loaded into the 8-bit shift register and then shifted out serially to the MISO pin most significant bit first.

The transmit sequence begins when the slave device receives the clock signal and the most significant bit of the data on its MOSI pin.

When data transfer is complete:

- The SPIF bit is set by hardware.
- An interrupt request is generated if SPIE bit is set and interrupt mask in the CCR register is cleared.

Clearing the SPIF bit is performed by the following software sequence:

- 1. An access to the SPICSR register while the SPIF bit is set
- 2. A write or a read to the SPIDR register

**Notes:** While the SPIF bit is set, all writes to the SPIDR register are inhibited until the SPICSR register is read.

The SPIF bit can be cleared during a second transmission; however, it must be cleared before the second SPIF bit in order to prevent an Overrun condition (see Section 0.1.5.2).

57

## 10.6.4 Clock Phase and Clock Polarity

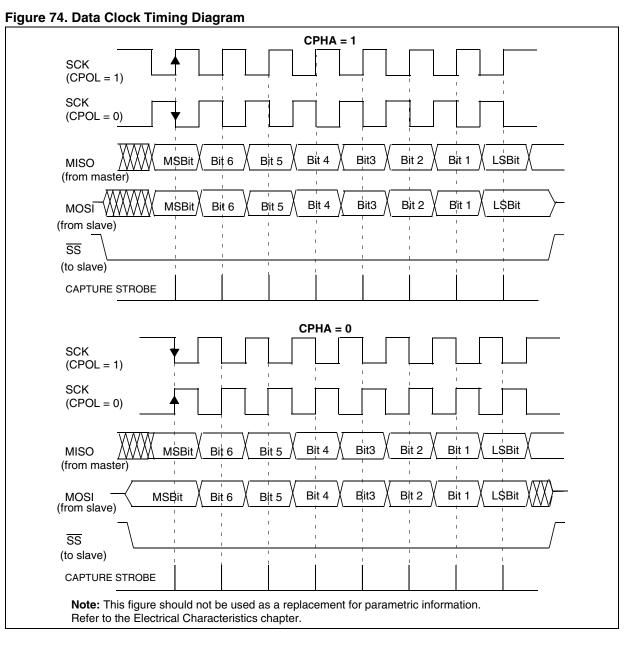

Four possible timing relationships may be chosen by software, using the CPOL and CPHA bits (See Figure 5).

**Note:** The idle state of SCK must correspond to the polarity selected in the SPICSR register (by pulling up SCK if CPOL = 1 or pulling down SCK if CPOL = 0).

The combination of the CPOL clock polarity and CPHA (clock phase) bits selects the data capture clock edge.

Figure 5 shows an SPI transfer with the four combinations of the CPHA and CPOL bits. The diagram may be interpreted as a master or slave timing diagram where the SCK pin, the MISO pin and the MOSI pin are directly connected between the master and the slave device.

**Note**: If CPOL is changed at the communication byte boundaries, the SPI must be disabled by resetting the SPE bit.

## 114/224

57

#### 10.6.5 Error Flags

#### 10.6.5.1 Master Mode Fault (MODF)

Master mode fault occurs when the master device's  $\overline{SS}$  pin is pulled low.

When a Master mode fault occurs:

- The MODF bit is set and an SPI interrupt request is generated if the SPIE bit is set.
- The SPE bit is reset. This blocks all output from the device and disables the SPI peripheral.
- The MSTR bit is reset, thus forcing the device into slave mode.

Clearing the MODF bit is done through a software sequence:

1. A read access to the SPICSR register while the MODF bit is set.

2. A write to the SPICR register.

**Notes:** To avoid any conflicts in an application with multiple slaves, the SS pin must be pulled high during the MODF bit clearing sequence. The SPE and MSTR bits may be restored to their original state during or after this clearing sequence.

Hardware does not allow the user to set the SPE and MSTR bits while the MODF bit is set except in the MODF bit clearing sequence.

In a slave device, the MODF bit can not be set, but in a multimaster configuration the device can be in slave mode with the MODF bit set.

The MODF bit indicates that there might have been a multimaster conflict and allows software to handle this using an interrupt routine and either perform a reset or return to an application default state.

#### 10.6.5.2 Overrun Condition (OVR)

An overrun condition occurs when the master device has sent a data byte and the slave device has not cleared the SPIF bit issued from the previously transmitted byte.

When an Overrun occurs:

 The OVR bit is set and an interrupt request is generated if the SPIE bit is set.

In this case, the receiver buffer contains the byte sent after the SPIF bit was last cleared. A read to the SPIDR register returns this byte. All other bytes are lost.

The OVR bit is cleared by reading the SPICSR register.

#### 10.6.5.3 Write Collision Error (WCOL)

A write collision occurs when the software tries to write to the SPIDR register while a data transfer is taking place with an external device. When this happens, the transfer continues uninterrupted and the software write will be unsuccessful.

Write collisions can occur both in master and slave mode. See also Section 0.1.3.2 Slave Select Management.

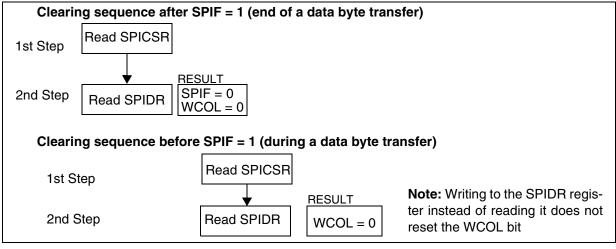

**Note:** A "read collision" will never occur since the received data byte is placed in a buffer in which access is always synchronous with the CPU operation.

The WCOL bit in the SPICSR register is set if a write collision occurs.

No SPI interrupt is generated when the WCOL bit is set (the WCOL bit is a status flag only).

Clearing the WCOL bit is done through a software sequence (see Figure 6).

#### Figure 75. Clearing the WCOL Bit (Write Collision Flag) Software Sequence

# 10.6.5.4 Single Master and Multimaster Configurations

There are two types of SPI systems:

- Single Master System
- Multimaster System

#### Single Master System

A typical single master system may be configured using a device as the master and four devices as slaves (see Figure 7).

The master device selects the individual slave devices by using four pins of a parallel port to control the four SS pins of the slave devices.

The  $\overline{SS}$  pins are pulled high during reset since the master device ports will be forced to be inputs at that time, thus disabling the slave devices.

**Note:** To prevent a bus conflict on the MISO line, the master allows only one active slave device during a transmission.

For more security, the slave device may respond to the master with the received data byte. Then the master will receive the previous byte back from the slave device if all MISO and MOSI pins are connected and the slave has not written to its SPIDR register.

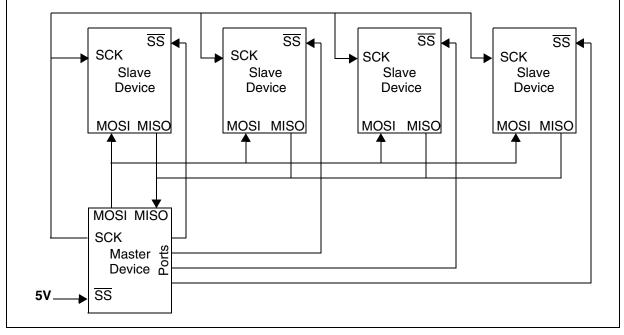

Other transmission security methods can use ports for handshake lines or data bytes with command fields.

#### Multimaster System

A multimaster system may also be configured by the user. Transfer of master control could be implemented using a handshake method through the I/O ports or by an exchange of code messages through the serial peripheral interface system.

The multimaster system is principally handled by the MSTR bit in the SPICR register and the MODF bit in the SPICSR register.

### 10.6.6 Low Power Modes

Mode	Description
WAIT	No effect on SPI. SPI interrupt events cause the device to exit from WAIT mode.
HALT	SPI registers are frozen. In HALT mode, the SPI is inactive. SPI oper- ation resumes when the device is woken up by an interrupt with "exit from HALT mode" capability. The data received is subsequently read from the SPIDR register when the soft- ware is running (interrupt vector fetching). If several data are received before the wake- up event, then an overrun error is generated. This error can be detected after the fetch of the interrupt routine that woke up the Device.

# 10.6.6.1 Using the SPI to wake up the device from Halt mode

In slave configuration, the SPI is able to wake up the device from HALT mode through a SPIF interrupt. The data received is subsequently read from the SPIDR register when the software is running (interrupt vector fetch). If multiple data transfers have been performed before software clears the SPIF bit, then the OVR bit is set by hardware.

**Note:** When waking up from HALT mode, if the SPI remains in Slave mode, it is recommended to perform an extra communications cycle to bring

the SPI from HALT mode state to normal state. If the SPI exits from Slave mode, it returns to normal state immediately.

**Caution:** The SPI can wake up the device from HALT mode only if the Slave Select signal (external SS pin or the SSI bit in the SPICSR register) is low when the device enters HALT mode. So, if Slave selection is configured as external (see Section 0.1.3.2), make sure the master drives a low level on the SS pin when the slave enters HALT mode.

#### 10.6.7 Interrupts

Interrupt Event	Event Flag	Enable Control Bit	Exit from Wait	Exit from Halt
SPI End of Transfer Event	SPIF			Yes
Master Mode Fault Event	MODF	SPIE	Yes	No
Overrun Error	OVR			

**Note**: The SPI interrupt events are connected to the same interrupt vector (see Interrupts chapter). They generate an interrupt if the corresponding Enable Control Bit is set and the interrupt mask in the CC register is reset (RIM instruction).

## 10.6.8 Register Description CONTROL REGISTER (SPICR)

Read/Write

Reset Value: 0000 xxxx (0xh)

7							0
SPIE	SPE	SPR2	MSTR	CPOL	CPHA	SPR1	SPR0

Bit 7 = **SPIE** Serial Peripheral Interrupt Enable This bit is set and cleared by software.

0: Interrupt is inhibited

1: An SPI interrupt is generated whenever an End of Transfer event, Master Mode Fault or Overrun error occurs (SPIF = 1, MODF = 1 or OVR = 1 in the SPICSR register)

### Bit 6 = **SPE** Serial Peripheral Output Enable

This bit is set and cleared by software. It is also cleared by hardware when, in master mode,  $\overline{SS} = 0$  (see Section 0.1.5.1 Master Mode Fault (MODF)). The SPE bit is cleared by reset, so the SPI peripheral is not initially connected to the external pins.

0: I/O pins free for general purpose I/O

1: SPI I/O pin alternate functions enabled

#### Bit 5 = **SPR2** Divider Enable

This bit is set and cleared by software and is cleared by reset. It is used with the SPR[1:0] bits to set the baud rate. Refer to Table 1 SPI Master Mode SCK Frequency.

0: Divider by 2 enabled

1: Divider by 2 disabled

Note: This bit has no effect in slave mode.

#### Bit 4 = MSTR Master Mode

This bit is set and cleared by software. It is also cleared by hardware when, in master mode,  $\overline{SS} = 0$  (see Section 0.1.5.1 Master Mode Fault (MODF)).

0: Slave mode

1: Master mode. The function of the SCK pin changes from an input to an output and the functions of the MISO and MOSI pins are reversed.

#### Bit 3 = CPOL Clock Polarity

This bit is set and cleared by software. This bit determines the idle state of the serial Clock. The CPOL bit affects both the master and slave modes.

0: SCK pin has a low level idle state

1: SCK pin has a high level idle state

**Note**: If CPOL is changed at the communication byte boundaries, the SPI must be disabled by resetting the SPE bit.

#### Bit 2 = CPHA Clock Phase

This bit is set and cleared by software.

- 0: The first clock transition is the first data capture edge.
- 1: The second clock transition is the first capture edge.

**Note:** The slave must have the same CPOL and CPHA settings as the master.

#### Bits 1:0 = SPR[1:0] Serial Clock Frequency

These bits are set and cleared by software. Used with the SPR2 bit, they select the baud rate of the SPI serial clock SCK output by the SPI in master mode.

Note: These 2 bits have no effect in slave mode.

#### Table 20. SPI Master Mode SCK Frequency

Serial Clock	SPR2	SPR1	SPR0
f <sub>CPU</sub> /4	1		0
f <sub>CPU</sub> /8	0	0	0
f <sub>CPU</sub> /16	0		1
f <sub>CPU</sub> /32	1		0
f <sub>CPU</sub> /64	0	1	0
f <sub>CPU</sub> /128	0		1

CONTROL/STATUS REGISTER (SPICSR)

Read/Write (some bits Read Only) Reset Value: 0000 0000 (00h)

7							0
SPIF	WCOL	OVR	MODF	-	SOD	SSM	SSI

Bit 7 = **SPIF** Serial Peripheral Data Transfer Flag (Read only)

This bit is set by hardware when a transfer has been completed. An interrupt is generated if SPIE = 1 in the SPICR register. It is cleared by a software sequence (an access to the SPICSR register followed by a write or a read to the SPIDR register).

- 0: Data transfer is in progress or the flag has been cleared.
- 1: Data transfer between the device and an external device has been completed.

**Note:** While the SPIF bit is set, all writes to the SPIDR register are inhibited until the SPICSR register is read.

Bit 6 = WCOL Write Collision status (Read only)

This bit is set by hardware when a write to the SPIDR register is done during a transmit sequence. It is cleared by a software sequence (see Figure 6).

0: No write collision occurred

1: A write collision has been detected

Bit 5 = **OVR** SPI Overrun error (Read only)

This bit is set by hardware when the byte currently being received in the shift register is ready to be transferred into the SPIDR register while SPIF = 1 (See Section 0.1.5.2). An interrupt is generated if SPIE = 1 in the SPICR register. The OVR bit is cleared by software reading the SPICSR register. 0: No overrun error

1: Overrun error detected

### Bit 4 = MODF Mode Fault flag (Read only)

This bit is set by hardware when the  $\overline{SS}$  pin is pulled low in master mode (see Section 0.1.5.1 Master Mode Fault (MODF)). An SPI interrupt can be generated if SPIE = 1 in the SPICR register. This bit is cleared by a software sequence (An access to the SPICSR register while MODF = 1 followed by a write to the SPICR register).

0: No master mode fault detected

1: A fault in master mode has been detected

Bit 3 = Reserved, must be kept cleared.

#### Bit 2 = SOD SPI Output Disable

This bit is set and cleared by software. When set, it disables the alternate function of the SPI output (MOSI in master mode / MISO in slave mode) 0: SPI output enabled (if SPE = 1) 1: SPI output disabled

#### Bit 1 = **SSM** *SS Management*

This bit is set and cleared by software. When set, it disables the alternate function of the SPI SS pin and uses the SSI bit value instead. See Section 0.1.3.2 Slave Select Management.

- 0: Hardware management (SS managed by external pin)
- 1: Software management (internal SS signal controlled by SSI bit. External SS pin free for general-purpose I/O)

#### Bit 0 = **SSI** *SS* Internal Mode

This bit is set and cleared by software. It <u>acts</u> as a 'chip select' by controlling the level of the SS slave select signal when the SSM bit is set.

0: Slave selected

1: Slave deselected

## DATA I/O REGISTER (SPIDR)

Read/Write Reset Value: Undefined

7							0
D7	D6	D5	D4	D3	D2	D1	D0

The SPIDR register is used to transmit and receive data on the serial bus. In a master device, a write to this register will initiate transmission/reception of another byte.

**Notes:** During the last clock cycle the SPIF bit is set, a copy of the received data byte in the shift register is moved to a buffer. When the user reads the serial peripheral data I/O register, the buffer is actually being read.

While the SPIF bit is set, all writes to the SPIDR register are inhibited until the SPICSR register is read.

**Warning:** A write to the SPIDR register places data directly into the shift register for transmission.

A read to the SPIDR register returns the value located in the buffer and not the content of the shift register (see Figure 1).

## Table 21. SPI Register Map and Reset Values

Address (Hex.)	Register Label	7	6	5	4	3	2	1	0
21	<b>SPIDR</b> Reset Value	MSB x	x	x	x	x	x	x	LSB x
22	SPICR Reset Value	SPIE 0	SPE 0	SPR2 0	MSTR 0	CPOL x	CPHA x	SPR1 x	SPR0 x
23	SPICSR Reset Value	SPIF 0	WCOL 0	OVR 0	MODF 0	0	SOD 0	SSM 0	SSI 0

## 10.7 LINSCI SERIAL COMMUNICATION INTERFACE (LIN MASTER/SLAVE)

#### 10.7.1 Introduction

The Serial Communications Interface (SCI) offers a flexible means of full-duplex data exchange with external equipment requiring an industry standard NRZ asynchronous serial data format. The SCI offers a very wide range of baud rates using two baud rate generator systems.

The LIN-dedicated features support the LIN (Local Interconnect Network) protocol for both master and slave nodes.

This chapter is divided into SCI Mode and LIN mode sections. For information on general SCI communications, refer to the SCI mode section. For LIN applications, refer to both the SCI mode and LIN mode sections.

#### 10.7.2 SCI Features

- Full duplex, asynchronous communications
- NRZ standard format (Mark/Space)
- Independently programmable transmit and receive baud rates up to 500K baud.
- Programmable data word length (8 or 9 bits)
- Receive buffer full, Transmit buffer empty and End of Transmission flags
- 2 receiver wake-up modes:
  - Address bit (MSB)
  - Idle line

5/

- Muting function for multiprocessor configurations
- Separate enable bits for Transmitter and Receiver
- Overrun, Noise and Frame error detection

- 6 interrupt sources
  - Transmit data register empty
  - Transmission complete
  - Receive data register full
  - Idle line received
  - Overrun error
  - Parity interrupt
- Parity control:
  - Transmits parity bit
  - Checks parity of received data byte
- Reduced power consumption mode

#### 10.7.3 LIN Features

- LIN Master
  - 13-bit LIN Synch Break generation
- LIN Slave
  - Automatic Header Handling
  - Automatic baud rate resynchronization based on recognition and measurement of the LIN Synch Field (for LIN slave nodes)
  - Automatic baud rate adjustment (at CPU frequency precision)
  - 11-bit LIN Synch Break detection capability
  - LIN Parity check on the LIN Identifier Field (only in reception)
  - LIN Error management
  - LIN Header Timeout
  - Hot plugging support

## LINSCI™ SERIAL COMMUNICATION INTERFACE (Cont'd)

#### **10.7.4 General Description**

The interface is externally connected to another device by two pins:

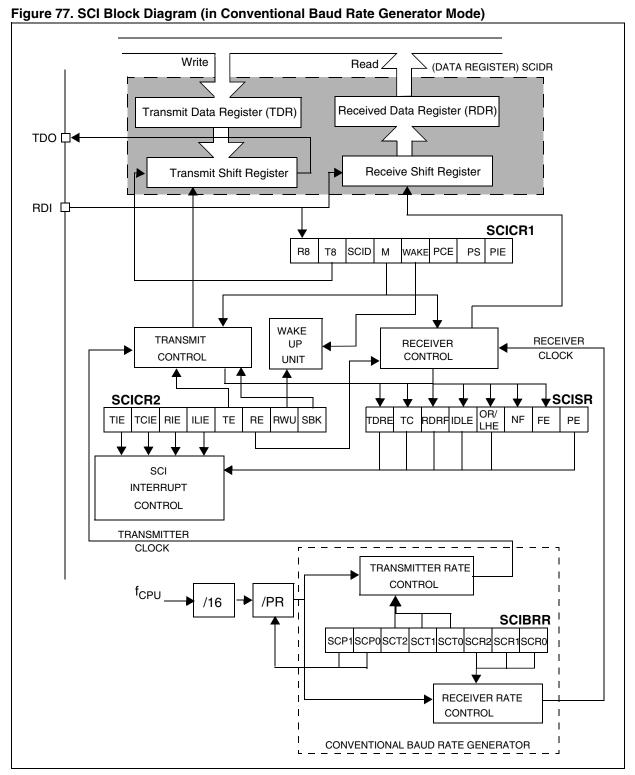

- TDO: Transmit Data Output. When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and nothing is to be transmitted, the TDO pin is at high level.
- RDI: Receive Data Input is the serial data input. Oversampling techniques are used for data recovery by discriminating between valid incoming data and noise.

Through these pins, serial data is transmitted and received as characters comprising:

- An Idle Line prior to transmission or reception
- A start bit
- A data word (8 or 9 bits) least significant bit first
- A Stop bit indicating that the character is complete

This interface uses three types of baud rate generator:

- A conventional type for commonly-used baud rates
- An extended type with a prescaler offering a very wide range of baud rates even with non-standard oscillator frequencies
- A LIN baud rate generator with automatic resynchronization

47/

123/224

## LINSCI<sup>TM</sup> SERIAL COMMUNICATION INTERFACE (SCI Mode) (Cont'd)

## 10.7.5 SCI Mode - Functional Description

#### **Conventional Baud Rate Generator Mode**

The block diagram of the Serial Control Interface in conventional baud rate generator mode is shown in Figure 1.

It uses four registers:

- 2 control registers (SCICR1 and SCICR2)
- A status register (SCISR)
- A baud rate register (SCIBRR)

#### **Extended Prescaler Mode**

Two additional prescalers are available in extended prescaler mode. They are shown in Figure 3.

- An extended prescaler receiver register (SCIER-PR)
- An extended prescaler transmitter register (SCI-ETPR)

#### Figure 78. Word Length Programming

#### 10.7.5.1 Serial Data Format

Word length may be selected as being either 8 or 9 bits by programming the M bit in the SCICR1 register (see Figure 2).

The TDO pin is in low state during the start bit.

The TDO pin is in high state during the stop bit.

An Idle character is interpreted as a continuous logic high level for 10 (or 11) full bit times.

A Break character is a character with a sufficient number of low level bits to break the normal data format followed by an extra "1" bit to acknowledge the start bit.

47/

9-bit Word length (M bit is set)										ć	Next Data Character		
		C	Data Cl	naract	er				Parity Bit		Next		
Start Bit	Bit0	Bit1	Bit2	Bit3	Bit4	Bit7	Bit8 Stop Bit		Start Bit				
		Start Bit											
		E	Break C	Charac	ter						Extra Start '1' Bit		
 <b>8-bi</b>			<b>th (M I</b> Data Cl	naract	er			Possi Pari Bit	ity t	Ne Do Sta			
Bit		0 Bit	:1 Bit	2 Bit	3 Bit	4 Bit	5 Bit	6 Bit	Bit		t		
		lo	dle Lin	e						Sta Bi			
 Break Character										Ext '1	ra Start Bit		

#### 10.7.5.2 Transmitter

The transmitter can send data words of either 8 or 9 bits depending on the M bit status. When the M bit is set, word length is 9 bits and the 9th bit (the MSB) has to be stored in the T8 bit in the SCICR1 register.

#### **Character Transmission**

During an SCI transmission, data shifts out least significant bit first on the TDO pin. In this mode, the SCIDR register consists of a buffer (TDR) between the internal bus and the transmit shift register (see Figure 1).

#### Procedure

- Select the M bit to define the word length.
- Select the desired baud rate using the SCIBRR and the SCIETPR registers.
- Set the TE bit to send a preamble of 10 (M = 0) or 11 (M = 1) consecutive ones (Idle Line) as first transmission.
- Access the SCISR register and write the data to send in the SCIDR register (this sequence clears the TDRE bit). Repeat this sequence for each data to be transmitted.

Clearing the TDRE bit is always performed by the following software sequence:

- 1. An access to the SCISR register
- 2. A write to the SCIDR register

The TDRE bit is set by hardware and it indicates:

- The TDR register is empty.
- The data transfer is beginning.
- The next data can be written in the SCIDR register without overwriting the previous data.

This flag generates an interrupt if the TIE bit is set and the I[1:0] bits are cleared in the CCR register.

When a transmission is taking place, a write instruction to the SCIDR register stores the data in the TDR register and which is copied in the shift register at the end of the current transmission. When no transmission is taking place, a write instruction to the SCIDR register places the data directly in the shift register, the data transmission starts, and the TDRE bit is immediately set.

When a character transmission is complete (after the stop bit) the TC bit is set and an interrupt is generated if the TCIE is set and the I[1:0] bits are cleared in the CCR register.

Clearing the TC bit is performed by the following software sequence:

1. An access to the SCISR register

2. A write to the SCIDR register

**Note:** The TDRE and TC bits are cleared by the same software sequence.

#### **Break Characters**

Setting the SBK bit loads the shift register with a break character. The break character length depends on the M bit (see Figure 2)

As long as the SBK bit is set, the SCI sends break characters to the TDO pin. After clearing this bit by software, the SCI inserts a logic 1 bit at the end of the last break character to guarantee the recognition of the start bit of the next character.

#### **Idle Line**

Setting the TE bit drives the SCI to send a preamble of 10 (M = 0) or 11 (M = 1) consecutive '1's (idle line) before the first character.

In this case, clearing and then setting the TE bit during a transmission sends a preamble (idle line) after the current word. Note that the preamble duration (10 or 11 consecutive '1's depending on the M bit) does not take into account the stop bit of the previous character.

**Note:** Resetting and setting the TE bit causes the data in the TDR register to be lost. Therefore the best time to toggle the TE bit is when the TDRE bit is set, that is, before writing the next byte in the SCIDR.

#### 10.7.5.3 Receiver

The SCI can receive data words of either 8 or 9 bits. When the M bit is set, word length is 9 bits and the MSB is stored in the R8 bit in the SCICR1 register.

#### Character reception

During a SCI reception, data shifts in least significant bit first through the RDI pin. In this mode, the SCIDR register consists or a buffer (RDR) between the internal bus and the received shift register (see Figure 1).

#### Procedure

- Select the M bit to define the word length.
- Select the desired baud rate using the SCIBRR and the SCIERPR registers.
- Set the RE bit, this enables the receiver which begins searching for a start bit.

When a character is received:

- The RDRF bit is set. It indicates that the content of the shift register is transferred to the RDR.
- An interrupt is generated if the RIE bit is set and the I[1:0] bits are cleared in the CCR register.
- The error flags can be set if a frame error, noise or an overrun error has been detected during reception.

Clearing the RDRF bit is performed by the following software sequence done by:

1. An access to the SCISR register

2. A read to the SCIDR register.

The RDRF bit must be cleared before the end of the reception of the next character to avoid an overrun error.

#### Idle Line

When an idle line is detected, there is the same procedure as a data received character plus an interrupt if the ILIE bit is set and the I[I1:0] bits are cleared in the CCR register.

#### **Overrun Error**

An overrun error occurs when a character is received when RDRF has not been reset. Data can not be transferred from the shift register to the TDR register as long as the RDRF bit is not cleared.

When an overrun error occurs:

- The OR bit is set.
- The RDR content will not be lost.
- The shift register will be overwritten.
- An interrupt is generated if the RIE bit is set and the I[11:0] bits are cleared in the CCR register.

The OR bit is reset by an access to the SCISR register followed by a SCIDR register read operation.

#### **Noise Error**

Oversampling techniques are used for data recovery by discriminating between valid incoming data and noise.

When noise is detected in a character:

- The NF bit is set at the rising edge of the RDRF bit.
- Data is transferred from the Shift register to the SCIDR register.
- No interrupt is generated. However this bit rises at the same time as the RDRF bit which itself generates an interrupt.

The NF bit is reset by a SCISR register read operation followed by a SCIDR register read operation.

#### **Framing Error**

A framing error is detected when:

- The stop bit is not recognized on reception at the expected time, following either a desynchronization or excessive noise.
- A break is received.

When the framing error is detected:

- the FE bit is set by hardware
- Data is transferred from the Shift register to the SCIDR register.
- No interrupt is generated. However this bit rises at the same time as the RDRF bit which itself generates an interrupt.

The FE bit is reset by a SCISR register read operation followed by a SCIDR register read operation.

#### **Break Character**

- When a break character is received, the SCI handles it as a framing error. To differentiate a break character from a framing error, it is necessary to read the SCIDR. If the received value is 00h, it is a break character. Otherwise it is a framing error.

f<sub>CPU</sub>

(16\*PR)\*RR

#### 10.7.5.4 Conventional Baud Rate Generation

The baud rates for the receiver and transmitter (Rx and Tx) are set independently and calculated as follows:

$$Tx = \frac{f_{CPU}}{(16 \cdot PR) \cdot TR} \qquad Rx =$$

with:

PR = 1, 3, 4 or 13 (see SCP[1:0] bits)

TR = 1, 2, 4, 8, 16, 32, 64,128

(see SCT[2:0] bits)

RR = 1, 2, 4, 8, 16, 32, 64,128

(see SCR[2:0] bits)

All these bits are in the SCIBRR register.

**Example:** If  $f_{CPU}$  is 8 MHz (normal mode) and if PR = 13 and TR = RR = 1, the transmit and receive baud rates are 38400 baud.

**Note:** The baud rate registers MUST NOT be changed while the transmitter or the receiver is enabled.

#### 10.7.5.5 Extended Baud Rate Generation

The extended prescaler option gives a very fine tuning on the baud rate, using a 255 value prescaler, whereas the conventional Baud Rate Generator retains industry standard software compatibility.

The extended baud rate generator block diagram is described in Figure 3.

The output clock rate sent to the transmitter or to the receiver will be the output from the 16 divider divided by a factor ranging from 1 to 255 set in the SCIERPR or the SCIETPR register.

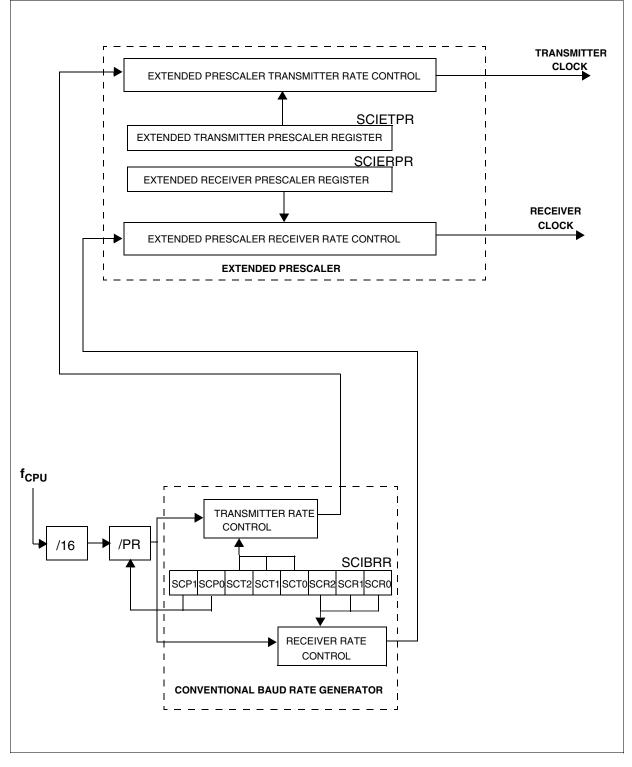

**Note:** The extended prescaler is activated by setting the SCIETPR or SCIERPR register to a value other than zero. The baud rates are calculated as follows:

$$Tx = \frac{f_{CPU}}{16 \cdot ETPR^{*}(PR^{*}TR)} Rx = \frac{f_{CPU}}{16 \cdot ERPR^{*}(PR^{*}RR)}$$

with:

ETPR = 1, ..., 255 (see SCIETPR register) ERPR = 1, ..., 255 (see SCIERPR register)

Figure 79. SCI Baud Rate and Extended Prescaler Block Diagram

#### 10.7.5.6 Receiver Muting and Wake-up Feature

In multiprocessor configurations it is often desirable that only the intended message recipient should actively receive the full message contents, thus reducing redundant SCI service overhead for all non-addressed receivers.

The non-addressed devices may be placed in sleep mode by means of the muting function.

Setting the RWU bit by software puts the SCI in sleep mode:

All the reception status bits can not be set.

All the receive interrupts are inhibited.

A muted receiver may be woken up in one of the following ways:

- by Idle Line detection if the WAKE bit is reset,

- by Address Mark detection if the WAKE bit is set.

#### **Idle Line Detection**

Receiver wakes up by Idle Line detection when the Receive line has recognized an Idle Line. Then the RWU bit is reset by hardware but the IDLE bit is not set.

This feature is useful in a multiprocessor system when the first characters of the message determine the address and when each message ends by an idle line: As soon as the line becomes idle, every receivers is waken up and analyse the first characters of the message which indicates the addressed receiver. The receivers which are not addressed set RWU bit to enter in mute mode. Consequently, they will not treat the next characters constituting the next part of the message. At the end of the message, an idle line is sent by the transmitter: this wakes up every receivers which are ready to analyse the addressing characters of the new message.

In such a system, the inter-characters space must be smaller than the idle time.

#### Address Mark Detection

5/

Receiver wakes up by Address Mark detection when it received a "1" as the most significant bit of a word, thus indicating that the message is an address. The reception of this particular word wakes up the receiver, resets the RWU bit and sets the RDRF bit, which allows the receiver to receive this word normally and to use it as an address word.

This feature is useful in a multiprocessor system when the most significant bit of each character (except for the break character) is reserved for Address Detection. As soon as the receivers received an address character (most significant bit = '1'), the receivers are waken up. The receivers which are not addressed set RWU bit to enter in mute mode. Consequently, they will not treat the next characters constituting the next part of the message.

#### 10.7.5.7 Parity Control

Hardware byte Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the SCICR1 register. Depending on the character format defined by the M bit, the possible SCI character formats are as listed in Table 1.

**Note**: In case of wake-up by an address mark, the MSB bit of the data is taken into account and not the parity bit

#### Table 22. Character Formats

M bit	PCE bit	Character format
0	0	SB   8 bit data   STB
0	1	SB   7-bit data   PB   STB
1	0	SB   9-bit data   STB
I	1	SB   8-bit data   PB   STB

**Legend:** SB = Start Bit, STB = Stop Bit, PB = Parity Bit

**Even parity:** The parity bit is calculated to obtain an even number of "1s" inside the character made of the 7 or 8 LSB bits (depending on whether M is equal to 0 or 1) and the parity bit.

Example: data = 00110101; 4 bits set => parity bit will be 0 if even parity is selected (PS bit = 0).

**Odd parity:** The parity bit is calculated to obtain an odd number of "1s" inside the character made of the 7 or 8 LSB bits (depending on whether M is equal to 0 or 1) and the parity bit.

Example: data = 00110101; 4 bits set => parity bit will be 1 if odd parity is selected (PS bit = 1).

**Transmission mode:** If the PCE bit is set then the MSB bit of the data written in the data register is not transmitted but is changed by the parity bit.

**Reception mode:** If the PCE bit is set then the interface checks if the received data byte has an even number of "1s" if even parity is selected (PS = 0) or an odd number of "1s" if odd parity is selected (PS = 1). If the parity check fails, the PE flag is set in the SCISR register and an interrupt is generated if PCIE is set in the SCICR1 register.

129/224

## LINSCI<sup>TM</sup> SERIAL COMMUNICATION INTERFACE (SCI Mode) (Cont'd)

## 10.7.6 Low Power Modes

Mode	Description
WAIT	No effect on SCI. SCI interrupts cause the device to exit from Wait mode.
HALT	SCI registers are frozen. In Halt mode, the SCI stops transmitting/re- ceiving until Halt mode is exited.

## 10.7.7 Interrupts

Interrupt Event	Event Flag	Enable Control Bit	Exit from Wait	Exit from Halt
Transmit Data Register Empty	TDRE	TIE		
Transmission Com- plete	тс	TCIE		
Received Data Ready to be Read	RDRF	RIE	Yes	No
Overrun Error or LIN Synch Error Detected	OR/ LHE	111		
Idle Line Detected	IDLE	ILIE		
Parity Error	PE	PIE		
LIN Header Detection	LHDF	LHIE		

The SCI interrupt events are connected to the same interrupt vector (see Interrupts chapter).

These events generate an interrupt if the corresponding Enable Control Bit is set and the interrupt mask in the CC register is reset (RIM instruction).

## 10.7.8 SCI Mode Register Description

#### STATUS REGISTER (SCISR) Read Only

Reset Value: 1100 0000 (C0h)

7							0
TDRE	тс	RDRF	IDLE	OR <sup>1)</sup>	NF <sup>1)</sup>	FE <sup>1)</sup>	PE <sup>1)</sup>

#### Bit 7 = **TDRE** *Transmit data register empty.*

This bit is set by hardware when the content of the TDR register has been transferred into the shift register. An interrupt is generated if the TIE = 1 in the SCICR2 register. It is cleared by a software sequence (an access to the SCISR register followed by a write to the SCIDR register).

0: Data is not transferred to the shift register

1: Data is transferred to the shift register

#### Bit 6 = TC Transmission complete.

This bit is set by hardware when transmission of a character containing Data is complete. An interrupt is generated if TCIE = 1 in the SCICR2 register. It is cleared by a software sequence (an access to the SCISR register followed by a write to the SCIDR register).

0: Transmission is not complete

1: Transmission is complete

**Note:** TC is not set after the transmission of a Preamble or a Break.

#### Bit 5 = **RDRF** Received data ready flag.

This bit is set by hardware when the content of the RDR register has been transferred to the SCIDR register. An interrupt is generated if RIE = 1 in the SCICR2 register. It is cleared by a software sequence (an access to the SCISR register followed by a read to the SCIDR register).

0: Data is not received

1: Received data is ready to be read

#### Bit 4 = IDLE Idle line detected.

This bit is set by hardware when an Idle Line is detected. An interrupt is generated if the ILIE = 1 in the SCICR2 register. It is cleared by a software sequence (an access to the SCISR register followed by a read to the SCIDR register).

0: No Idle Line is detected

1: Idle Line is detected

5/

**Note:** The IDLE bit will not be set again until the RDRF bit has been set itself (that is, a new idle line occurs).

#### Bit 3 = **OR** Overrun error

The OR bit is set by hardware when the word currently being received in the shift register is ready to be transferred into the RDR register whereas RDRF is still set. An interrupt is generated if RIE = 1 in the SCICR2 register. It is cleared by a software sequence (an access to the SCISR register followed by a read to the SCIDR register). 0: No Overrun error

1: Overrun error detected

**Note:** When this bit is set, RDR register contents will not be lost but the shift register will be overwritten.

#### Bit 2 = NF Character Noise flag

This bit is set by hardware when noise is detected on a received character. It is cleared by a software sequence (an access to the SCISR register followed by a read to the SCIDR register).

0: No noise

1: Noise is detected

**Note:** This bit does not generate interrupt as it appears at the same time as the RDRF bit which itself generates an interrupt.

#### Bit 1 = FE Framing error.

This bit is set by hardware when a desynchronization, excessive noise or a break character is detected. It is cleared by a software sequence (an access to the SCISR register followed by a read to the SCIDR register).

- 0: No Framing error
- 1: Framing error or break character detected

#### Notes:

This bit does not generate an interrupt as it appears at the same time as the RDRF bit which itself generates an interrupt. If the word currently being transferred causes both a frame error and an overrun error, it will be transferred and only the OR bit will be set.

#### Bit 0 = **PE** Parity error.

This bit is set by hardware when a byte parity error occurs (if the PCE bit is set) in receiver mode. It is cleared by a software sequence (a read to the status register followed by an access to the SCIDR data register). An interrupt is generated if PIE = 1 in the SCICR1 register.

0: No parity error

1: Parity error detected

## LINSCI™ SERIAL COMMUNICATION INTERFACE (SCI Mode) (Cont'd) CONTROL REGISTER 1 (SCICR1)

#### Read/Write

Reset Value: x000 0000 (x0h)

7							0
R8	Т8	SCID	М	WAKE	PCE <sup>1)</sup>	PS	PIE

<sup>1)</sup>This bit has a different function in LIN mode, please refer to the LIN mode register description.

#### Bit 7 = R8 Receive data bit 8.

This bit is used to store the 9th bit of the received word when M = 1.

#### Bit 6 = T8 Transmit data bit 8.

This bit is used to store the 9th bit of the transmitted word when M = 1.

Bit 5 = **SCID** *Disabled for low power consumption* When this bit is set the SCI prescalers and outputs are stopped and the end of the current byte transfer in order to reduce power consumption. This bit is set and cleared by software.

0: SCI enabled

1: SCI prescaler and outputs disabled

#### Bit 4 = **M** Word length.

This bit determines the word length. It is set or cleared by software.

0: 1 Start bit, 8 Data bits, 1 Stop bit

1: 1 Start bit, 9 Data bits, 1 Stop bit

**Note**: The M bit must not be modified during a data transfer (both transmission and reception).

#### Bit 3 = **WAKE** Wake-Up method.

This bit determines the SCI Wake-Up method, it is set or cleared by software.

0: Idle Line

1: Address Mark

**Note:** If the LINE bit is set, the WAKE bit is deactivated and replaced by the LHDM bit.

#### Bit 2 = **PCE** Parity control enable.

This bit is set and cleared by software. It selects the hardware parity control (generation and detection for byte parity, detection only for LIN parity). 0: Parity control disabled

1: Parity control enabled

#### Bit 1 = **PS** Parity selection.

This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity will be selected after the current byte.

0: Even parity

1: Odd parity

#### Bit 0 = **PIE** Parity interrupt enable.

This bit enables the interrupt capability of the hardware parity control when a parity error is detected (PE bit set). The parity error involved can be a byte parity error (if bit PCE is set and bit LPE is reset) or a LIN parity error (if bit PCE is set and bit LPE is set).

0: Parity error interrupt disabled

1: Parity error interrupt enabled

Δ

## **CONTROL REGISTER 2 (SCICR2)**

Read/Write F

-

Reset Value: 0000 0000 (00h)
------------------------------

'							0
TIE	TCIE	RIE	ILIE	TE	RE	RWU <sup>1)</sup>	SBK <sup>1)</sup>

<sup>1)</sup>This bit has a different function in LIN mode, please refer to the LIN mode register description.

#### Bit 7 = **TIE** *Transmitter interrupt enable*. This bit is set and cleared by software. 0: Interrupt is inhibited

1: In SCI interrupt is generated whenever TDRE = 1 in the SCISR register

Bit 6 = **TCIE** Transmission complete interrupt enable

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: An SCI interrupt is generated whenever TC = 1 in the SCISR register

## Bit 5 = **RIE** Receiver interrupt enable.

- This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: An SCI interrupt is generated whenever OR = 1 or RDRF = 1 in the SCISR register

### Bit 4 = ILIE Idle line interrupt enable.

- This bit is set and cleared by software. 0: Interrupt is inhibited
- 1: An SCI interrupt is generated whenever IDLE = 1 in the SCISR register.

### Bit 3 = **TE** Transmitter enable.

This bit enables the transmitter. It is set and cleared by software.

0: Transmitter is disabled

1: Transmitter is enabled

### Notes:

- During transmission, a "0" pulse on the TE bit ("0" followed by "1") sends a preamble (idle line) after the current word.
- When TE is set there is a 1 bit-time delay before the transmission starts.

### Bit 2 = **RE** Receiver enable.

This bit enables the receiver. It is set and cleared by software.

0: Receiver is disabled in the SCISR register

1: Receiver is enabled and begins searching for a start bit

Bit 1 = RWU Receiver wake-up.

This bit determines if the SCI is in mute mode or not. It is set and cleared by software and can be cleared by hardware when a wake-up sequence is recognized.

0: Receiver in active mode

1: Receiver in mute mode

#### Notes:

- Before selecting Mute mode (by setting the RWU bit) the SCI must first receive a data byte, otherwise it cannot function in Mute mode with wakeup by Idle line detection.
- In Address Mark Detection Wake-Up configuration (WAKE bit = 1) the RWU bit cannot be modified by software while the RDRF bit is set.

#### Bit 0 = SBK Send break.

This bit set is used to send break characters. It is set and cleared by software.

0: No break character is transmitted

1: Break characters are transmitted

Note: If the SBK bit is set to "1" and then to "0", the transmitter will send a BREAK word at the end of the current word.

## **DATA REGISTER (SCIDR)**

### Read/Write

**Reset Value: Undefined** 

Contains the Received or Transmitted data character, depending on whether it is read from or written to.

7							0	
DR7	DR6	DR5	DR4	DR3	DR2	DR1	DR0	

The Data register performs a double function (read and write) since it is composed of two registers, one for transmission (TDR) and one for reception (RDR).

The TDR register provides the parallel interface between the internal bus and the output shift register (see Figure 1).

The RDR register provides the parallel interface between the input shift register and the internal bus (see Figure 1).

## LINSCI<sup>TM</sup> SERIAL COMMUNICATION INTERFACE (SCI Mode) (Cont'd)

## BAUD RATE REGISTER (SCIBRR)

## Read/Write

Reset Value: 0000 0000 (00h)

7							0
SCP1	SCP0	SCT2	SCT1	SCT0	SCR2	SCR1	SCR0

**Note:** When LIN slave mode is disabled, the SCI-BRR register controls the conventional baud rate generator.

#### Bits 7:6 = SCP[1:0] First SCI Prescaler

These 2 prescaling bits allow several standard clock division ranges:

PR Prescaling factor	SCP1	SCP0
1	0	0
3	SCP1           0           1	1
4	4	0
13		1

Bits 5:3 = **SCT[2:0]** *SCI Transmitter rate divisor* These 3 bits, in conjunction with the SCP1 and SCP0 bits define the total division applied to the bus clock to yield the transmit rate clock in conventional Baud Rate Generator mode.

TR dividing factor	SCT2	SCT1	SCT0
1		0	0
2	0	0	1
4	0	-1	0
8		1	1
16		0	0
32	1	0	1
64		1	0
128		1	1

Bits 2:0 = **SCR[2:0]** *SCI Receiver rate divider.* These 3 bits, in conjunction with the SCP[1:0] bits define the total division applied to the bus clock to yield the receive rate clock in conventional Baud Rate Generator mode.

RR dividing factor	SCR2	SCR1	SCR0
1		0	0
2	_	0	1

# EXTENDED RECEIVE PRESCALER DIVISION REGISTER (SCIERPR)

Read/Write

57

Reset Value: 0000 0000 (00h)

7							0
ERPR							
7	6	5	4	3	2	1	0

Bits 7:0 = **ERPR[7:0]** 8-bit Extended Receive Prescaler Register.

The extended Baud Rate Generator is activated when a value other than 00h is stored in this register. The clock frequency from the 16 divider (see Figure 3) is divided by the binary factor set in the SCIERPR register (in the range 1 to 255).

The extended baud rate generator is not active after a reset.

# EXTENDED TRANSMIT PRESCALER DIVISION REGISTER (SCIETPR)

## Read/Write

Reset Value:0000 0000 (00h)

7							0
ETPR							
7	6	5	4	3	2	1	0

Bits 7:0 = **ETPR[7:0]** 8-bit Extended Transmit Prescaler Register.

The extended Baud Rate Generator is activated when a value other than 00h is stored in this register. The clock frequency from the 16 divider (see Figure 3) is divided by the binary factor set in the SCIETPR register (in the range 1 to 255).

The extended baud rate generator is not active after a reset.

**Note:** In LIN slave mode, the Conventional and Extended Baud Rate Generators are disabled.

#### 10.7.9 LIN Mode - Functional Description.

The block diagram of the Serial Control Interface, in LIN slave mode is shown in Figure 5.

It uses six registers:

- 3 control registers: SCICR1, SCICR2 and SCICR3
- 2 status registers: the SCISR register and the LHLR register mapped at the SCIERPR address
- A baud rate register: LPR mapped at the SCI-BRR address and an associated fraction register LPFR mapped at the SCIETPR address

The bits dedicated to LIN are located in the SCICR3. Refer to the register descriptions in Section 0.1.10 for the definitions of each bit.

#### 10.7.9.1 Entering LIN Mode

To use the LINSCI in LIN mode the following configuration must be set in SCICR3 register:

- Clear the M bit to configure 8-bit word length.
- Set the LINE bit.

#### Master

To enter master mode the LSLV bit must be reset In this case, setting the SBK bit will send 13 low bits.

Then the baud rate can programmed using the SCIBRR, SCIERPR and SCIETPR registers.

In LIN master mode, the Conventional and / or Extended Prescaler define the baud rate (as in standard SCI mode)

#### Slave

Set the LSLV bit in the SCICR3 register to enter LIN slave mode. In this case, setting the SBK bit will have no effect.

In LIN Slave mode the LIN baud rate generator is selected instead of the Conventional or Extended Prescaler. The LIN baud rate generator is common to the transmitter and the receiver.

Then the baud rate can be programmed using LPR and LPRF registers.

**Note:** It is mandatory to set the LIN configuration first before programming LPR and LPRF, because the LIN configuration uses a different baud rate generator from the standard one.

#### 10.7.9.2 LIN Transmission

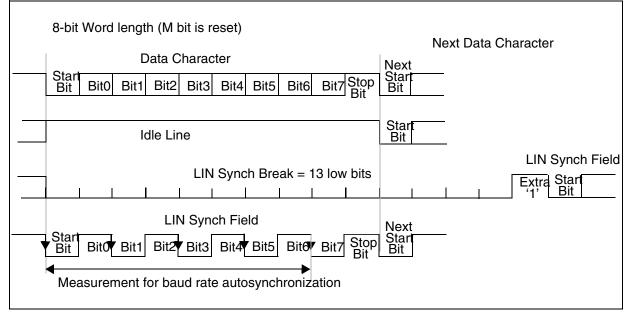

In LIN mode the same procedure as in SCI mode has to be applied for a LIN transmission.

To transmit the LIN Header the proceed as follows:

- First set the SBK bit in the SCICR2 register to start transmitting a 13-bit LIN Synch Break
- reset the SBK bit
- Load the LIN Synch Field (0x55) in the SCIDR register to request Synch Field transmission
- Wait until the SCIDR is empty (TDRE bit set in the SCISR register)
- Load the LIN message Identifier in the SCIDR register to request Identifier transmission.

#### Figure 80. LIN Characters

**لرک**ا

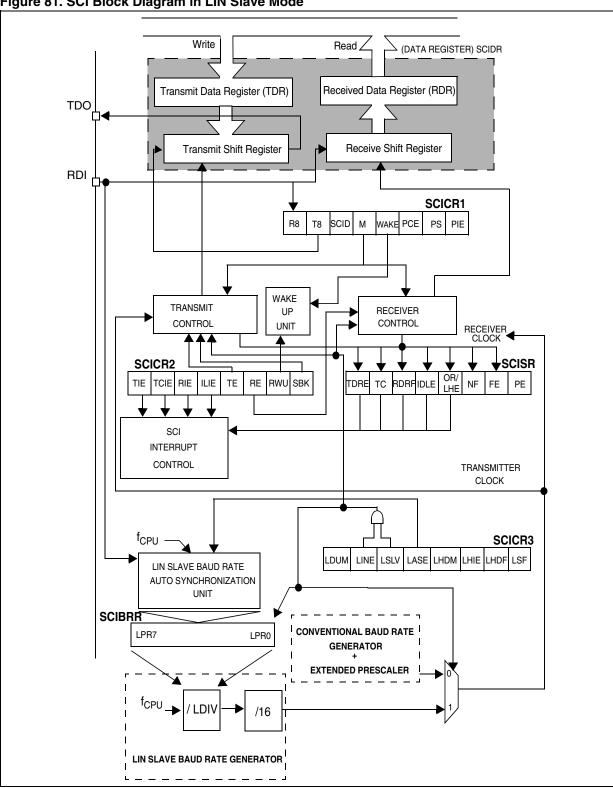

Figure 81. SCI Block Diagram in LIN Slave Mode

#### 10.7.9.3 LIN Reception

In LIN mode the reception of a byte is the same as in SCI mode but the LINSCI has features for handling the LIN Header automatically (identifier detection) or semiautomatically (Synch Break detection) depending on the LIN Header detection mode. The detection mode is selected by the LHDM bit in the SCICR3.

Additionally, an automatic resynchronization feature can be activated to compensate for any clock deviation, for more details please refer to Section 0.1.9.5 LIN Baud Rate.

#### LIN Header Handling by a Slave

Depending on the LIN Header detection method the LINSCI will signal the detection of a LIN Header after the LIN Synch Break or after the Identifier has been successfully received.

#### Note:

5/

It is recommended to combine the Header detection function with Mute mode. Putting the LINSCI in Mute mode allows the detection of Headers only and prevents the reception of any other characters.

This mode can be used to wait for the next Header without being interrupted by the data bytes of the current message in case this message is not relevant for the application.

#### Synch Break Detection (LHDM = 0):

When a LIN Synch Break is received:

- The RDRF bit in the SCISR register is set. It indicates that the content of the shift register is transferred to the SCIDR register, a value of 0x00 is expected for a Break.
- The LHDF flag in the SCICR3 register indicates that a LIN Synch Break Field has been detected.
- An interrupt is generated if the LHIE bit in the SCICR3 register is set and the I[1:0] bits are cleared in the CCR register.
- Then the LIN Synch Field is received and measured.
  - If automatic resynchronization is enabled (LA-SE bit = 1), the LIN Synch Field is not transferred to the shift register: there is no need to clear the RDRF bit.
  - If automatic resynchronization is disabled (LA-SE bit = 0), the LIN Synch Field is received as a normal character and transferred to the SCIDR register and RDRF is set.

#### Note:

In LIN slave mode, the FE bit detects all frame error which does not correspond to a break.

#### Identifier Detection (LHDM = 1):

This case is the same as the previous one except that the LHDF and the RDRF flags are set only after the entire header has been received (this is true whether automatic resynchronization is enabled or not). This indicates that the LIN Identifier is available in the SCIDR register.

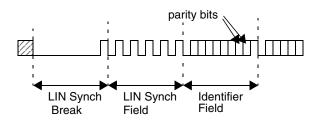

#### Notes:

During LIN Synch Field measurement, the SCI state machine is switched off: no characters are transferred to the data register.

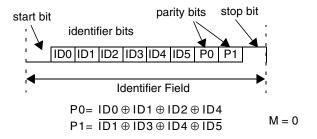

#### LIN Slave parity

In LIN Slave mode (LINE and LSLV bits are set) LIN parity checking can be enabled by setting the PCE bit.

In this case, the parity bits of the LIN Identifier Field are checked. The identifier character is recognized as the 3<sup>rd</sup> received character after a break character (included):

The bits involved are the two MSB positions (7th and 8th bits if M = 0; 8th and 9th bits if M = 0) of the identifier character. The check is performed as specified by the LIN specification:

#### 10.7.9.4 LIN Error Detection

#### LIN Header Error Flag

The LIN Header Error Flag indicates that an invalid LIN Header has been detected.

When a LIN Header Error occurs:

- The LHE flag is set
- An interrupt is generated if the RIE bit is set and the I[1:0] bits are cleared in the CCR register.

If autosynchronization is enabled (LASE bit = 1), this can mean that the LIN Synch Field is corrupted, and that the SCI is in a blocked state (LSF bit is set). The only way to recover is to reset the LSF bit and then to clear the LHE bit.

 The LHE bit is reset by an access to the SCISR register followed by a read of the SCIDR register.

#### LHE/OVR Error Conditions

When Auto Resynchronization is disabled (LASE bit = 0), the LHE flag detects:

- That the received LIN Synch Field is not equal to 55h.
- That an overrun occurred (as in standard SCI mode)
- Furthermore, if LHDM is set it also detects that a LIN Header Reception Timeout occurred (only if LHDM is set).

When the LIN auto-resynchronization is enabled (LASE bit = 1), the LHE flag detects:

- That the deviation error on the Synch Field is outside the LIN specification which allows up to +/-15.5% of period deviation between the slave and master oscillators.
- A LIN Header Reception Timeout occurred.
   If T<sub>HEADER</sub> > T<sub>HEADER\_MAX</sub> then the LHE flag is set. Refer to Figure 6. (only if LHDM is set to 1)
- An overflow during the Synch Field Measurement, which leads to an overflow of the divider registers. If LHE is set due to this error then the SCI goes into a blocked state (LSF bit is set).
- That an overrun occurred on Fields other than the Synch Field (as in standard SCI mode)

#### **Deviation Error on the Synch Field**

The deviation error is checking by comparing the current baud rate (relative to the slave oscillator) with the received LIN Synch Field (relative to the master oscillator). Two checks are performed in parallel:

 The first check is based on a measurement between the first falling edge and the last falling edge of the Synch Field. Let us refer to this period deviation as D:

If the LHE flag is set, it means that:

D > 15.625%

If LHE flag is not set, it means that:

D < 16.40625%

If  $15.625\% \le D < 16.40625\%$ , then the flag can be either set or reset depending on the dephasing between the signal on the RDI line and the CPU clock.

 The second check is based on the measurement of each bit time between both edges of the Synch Field: this checks that each of these bit times is large enough compared to the bit time of the current baud rate.

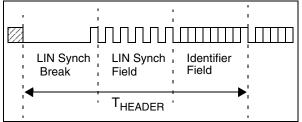

When LHE is set due to this error then the SCI goes into a blocked state (LSF bit is set).

#### LIN Header Time-out Error

When the LIN Identifier Field Detection Method is used (by configuring LHDM to 1) or when LIN auto-resynchronization is enabled (LASE bit = 1), the LINSCI automatically monitors the  $T_{HEADER\_MAX}$  condition given by the LIN protocol.

If the entire Header (up to and including the STOP bit of the LIN Identifier Field) is not received within the maximum time limit of 57 bit times then a LIN Header Error is signalled and the LHE bit is set in the SCISR register.

#### Figure 82. LIN Header Reception Timeout

The time-out counter is enabled at each break detection. It is stopped in the following conditions:

- A LIN Identifier Field has been received

- An LHE error occurred (other than a timeout error).

- A software reset of LSF bit (transition from high to low) occurred during the analysis of the LIN Synch Field or

If LHE bit is set due to this error during the LIN Synchr Field (if LASE bit = 1) then the SCI goes into a blocked state (LSF bit is set).

### LINSCI<sup>TM</sup> SERIAL COMMUNICATION INTERFACE (LIN Mode) (Cont'd)

If LHE bit is set due to this error during Fields other than LIN Synch Field or if LASE bit is reset then the current received Header is discarded and the SCI searches for a new Break Field.

#### Note on LIN Header Time-out Limit

According to the LIN specification, the maximum length of a LIN Header which does not cause a timeout is equal to 1.4 \* (34 + 1) = 49 T<sub>BIT MASTER</sub>.

T<sub>BIT MASTER</sub> refers to the master baud rate.

When checking this timeout, the slave node is desynchronized for the reception of the LIN Break and Synch fields. Consequently, a margin must be allowed, taking into account the worst case: This occurs when the LIN identifier lasts exactly 10  $T_{BIT\_MASTER}$  periods. In this case, the LIN Break and Synch fields last 49 - 10 =  $39T_{BIT\_MASTER}$  periods.

Assuming the slave measures these first 39 bits with a desynchronized clock of 15.5%. This leads to a maximum allowed Header Length of:

39 x (1/0.845)  $T_{BIT\_MASTER}$  + 10 $T_{BIT\_MASTER}$ 

 $= 56.15 T_{BIT_SLAVE}$ 

57/

A margin is provided so that the time-out occurs when the header length is greater than 57  $T_{BIT\_SLAVE}$  periods. If it is less than or equal to 57  $T_{BIT\_SLAVE}$  periods, then no timeout occurs.

#### LIN Header Length

Even if no timeout occurs on the LIN Header, it is possible to have access to the effective LIN header Length ( $T_{HEADER}$ ) through the LHL register. This allows monitoring at software level the  $T_{FRAME MAX}$  condition given by the LIN protocol.

This feature is only available when LHDM bit = 1 or when LASE bit = 1.

#### Mute Mode and Errors

In mute mode when LHDM bit = 1, if an LHE error occurs during the analysis of the LIN Synch Field or if a LIN Header Time-out occurs then the LHE bit is set but it does not wake up from mute mode. In this case, the current header analysis is discarded. If needed, the software has to reset LSF bit. Then the SCI searches for a new LIN header.

In mute mode, if a framing error occurs on a data (which is not a break), it is discarded and the FE bit is not set.

When LHDM bit = 1, any LIN header which respects the following conditions causes a wake-up from mute mode:

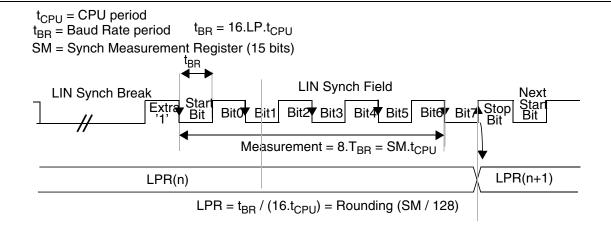

- A valid LIN Break Field (at least 11 dominant bits followed by a recessive bit)

- A valid LIN Synch Field (without deviation error)

- A LIN Identifier Field without framing error. Note that a LIN parity error on the LIN Identifier Field does not prevent wake-up from mute mode.

- No LIN Header Time-out should occur during Header reception.

#### Figure 83. LIN Synch Field Measurement

### LINSCI<sup>TM</sup> SERIAL COMMUNICATION INTERFACE (LIN Mode) (Cont'd)

#### 10.7.9.5 LIN Baud Rate

Baud rate programming is done by writing a value in the LPR prescaler or performing an automatic resynchronization as described below.

#### Automatic Resynchronization

To automatically adjust the baud rate based on measurement of the LIN Synch Field:

- Write the nominal LIN Prescaler value (usually depending on the nominal baud rate) in the LPFR / LPR registers.
- Set the LASE bit to enable the Auto Synchronization Unit.

When Auto Synchronization is enabled, after each LIN Synch Break, the time duration between five falling edges on RDI is sampled on  $f_{CPU}$  and the result of this measurement is stored in an internal 15-bit register called SM (not user accessible) (See Figure 7). Then the LDIV value (and its associated LPFR and LPR registers) are automatically updated at the end of the fifth falling edge. During LIN Synch field measurement, the SCI state machine is stopped and no data is transferred to the data register.

#### 10.7.9.6 LIN Slave Baud Rate Generation

In LIN mode, transmission and reception are driven by the LIN baud rate generator

**Note:** LIN Master mode uses the Extended or Conventional prescaler register to generate the baud rate.

If LINE bit = 1 and LSLV bit = 1 then the Conventional and Extended Baud Rate Generators are disabled: the baud rate for the receiver and transmitter are both set to the same value, depending on the LIN Slave baud rate generator:

$$Tx = Rx = \frac{f_{CPU}}{(16 \cdot LDIV)}$$

with:

LDIV is an unsigned fixed point number. The mantissa is coded on 8 bits in the LPR register and the fraction is coded on 4 bits in the LPFR register.

If LASE bit = 1 then LDIV is automatically updated at the end of each LIN Synch Field.

Three registers are used internally to manage the auto-update of the LIN divider (LDIV):

- LDIV\_NOM (nominal value written by software at LPR/LPFR addresses)

- LDIV\_MEAS (results of the Field Synch measurement)

- LDIV (used to generate the local baud rate)

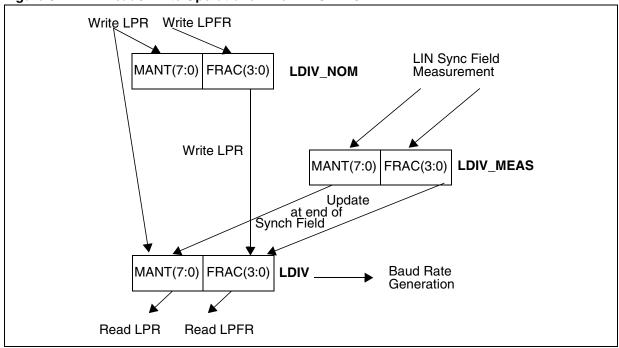

The control and interactions of these registers is explained in Figure 8 and Figure 9. It depends on the LDUM bit setting (LIN Divider Update Method)

#### Note:

As explained in Figure 8 and Figure 9, LDIV can be updated by two concurrent actions: a transfer from LDIV\_MEAS at the end of the LIN Sync Field and a transfer from LDIV\_NOM due to a software write of LPR. If both operations occur at the same time, the transfer from LDIV\_NOM has priority.

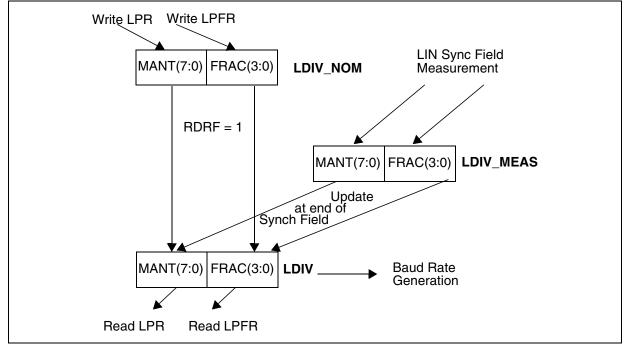

## LINSCI<sup>TM</sup> SERIAL COMMUNICATION INTERFACE (LIN Mode) (Cont'd)

۲7/

#### 10.7.9.7 LINSCI Clock Tolerance

#### LINSCI Clock Tolerance when unsynchronized

When LIN slaves are unsynchronized (meaning no characters have been transmitted for a relatively long time), the maximum tolerated deviation of the LINSCI clock is +/-15%.

If the deviation is within this range then the LIN Synch Break is detected properly when a new reception occurs.

This is made possible by the fact that masters send 13 low bits for the LIN Synch Break, which can be interpreted as 11 low bits (13 bits -15% = 11.05) by a "fast" slave and then considered as a LIN Synch Break. According to the LIN specification, a LIN Synch Break is valid when its duration is greater than  $t_{\text{SBRKTS}} = 10$ . This means that the LIN Synch Break must last at least 11 low bits.

**Note:** If the period desynchronization of the slave is +15% (slave too slow), the character "00h" which represents a sequence of 9 low bits must not be interpreted as a break character (9 bits + 15% = 10.35). Consequently, a valid LIN Synch break must last at least 11 low bits.

#### LINSCI Clock Tolerance when Synchronized

When synchronization has been performed, following reception of a LIN Synch Break, the LINS-CI, in LIN mode, has the same clock deviation tolerance as in SCI mode, which is explained below:

During reception, each bit is oversampled 16 times. The mean of the 8th, 9th and 10th samples is considered as the bit value.

Consequently, the clock frequency should not vary more than 6/16 (37.5%) within one bit.

The sampling clock is resynchronized at each start bit, so that when receiving 10 bits (one start bit, 1 data byte, 1 stop bit), the clock deviation should not exceed 3.75%.

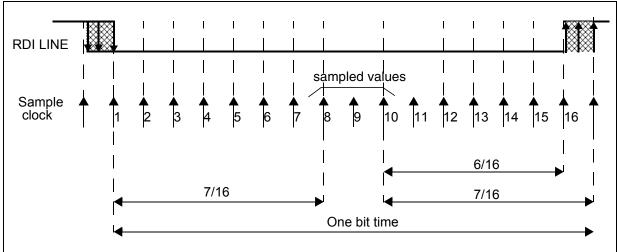

#### 10.7.9.8 Clock Deviation Causes

The causes which contribute to the total deviation are:

- D<sub>TRA</sub>: Deviation due to transmitter error.
   Note: The transmitter can be either a master or a slave (in case of a slave listening to the response of another slave).
- D<sub>MEAS</sub>: Error due to the LIN Synch measurement performed by the receiver.
- D<sub>QUANT</sub>: Error due to the baud rate quantization of the receiver.
- D<sub>REC</sub>: Deviation of the local oscillator of the receiver: This deviation can occur during the reception of one complete LIN message assuming that the deviation has been compensated at the beginning of the message.
- D<sub>TCL</sub>: Deviation due to the transmission line (generally due to the transceivers)

All the deviations of the system should be added and compared to the LINSCI clock tolerance:

 $D_{TRA} + D_{MEAS} + D_{QUANT} + D_{REC} + D_{TCL} < 3.75\%$ 

### Figure 86.Bit Sampling in Reception Mode

## LINSCI™ SERIAL COMMUNICATION INTERFACE (LIN Mode) (Cont'd)

#### 10.7.9.9 Error due to LIN Synch measurement

The LIN Synch Field is measured over eight bit times.

This measurement is performed using a counter clocked by the CPU clock. The edge detections are performed using the CPU clock cycle.

This leads to a precision of 2 CPU clock cycles for the measurement which lasts 16\*8\*LDIV clock cycles.

Consequently, this error (D<sub>MEAS</sub>) is equal to:

#### 2 / (128\*LDIV<sub>MIN</sub>).

57/

 $LDIV_{MIN}$  corresponds to the minimum LIN prescaler content, leading to the maximum baud rate, taking into account the maximum deviation of +/-15%.

#### 10.7.9.10 Error due to Baud Rate Quantization

The baud rate can be adjusted in steps of 1 / (16 \* LDIV). The worst case occurs when the "real" baud rate is in the middle of the step.

This leads to a quantization error ( $D_{QUANT}$ ) equal to 1 / (2\*16\*LDIV<sub>MIN</sub>).

# 10.7.9.11 Impact of Clock Deviation on Maximum Baud Rate

The choice of the nominal baud rate (LDIV<sub>NOM</sub>) will influence both the quantization error ( $D_{QUANT}$ ) and the measurement error ( $D_{MEAS}$ ). The worst case occurs for LDIV<sub>MIN</sub>.

Consequently, at a given CPU frequency, the maximum possible nominal baud rate (LPR<sub>MIN</sub>) should be chosen with respect to the maximum tolerated deviation given by the equation:

D<sub>TRA</sub> + 2 / (128\*LDIV<sub>MIN</sub>) + 1 / (2\*16\*LDIV<sub>MIN</sub>)

 $+ D_{REC} + D_{TCL} < 3.75\%$ 

Example:

A nominal baud rate of 20Kbits/s at  $T_{CPU}$  = 125ns (8 MHz) leads to LDIV<sub>NOM</sub> = 25d.

LDIV<sub>MIN</sub> = 25 - 0.15\*25 = 21.25

D<sub>MEAS</sub> = 2 / (128\*LDIV<sub>MIN</sub>) \* 100 = 0.00073% D<sub>QUANT</sub> = 1 / (2\*16\*LDIV<sub>MIN</sub>) \* 100 = 0.0015%

#### LIN Slave systems

For LIN Slave systems (the LINE and LSLV bits are set), receivers wake up by LIN Synch Break or LIN Identifier detection (depending on the LHDM bit).

#### Hot Plugging Feature for LIN Slave Nodes

In LIN Slave Mute Mode (the LINE, LSLV and RWU bits are set) it is possible to hot plug to a network during an ongoing communication flow. In this case the SCI monitors the bus on the RDI line until 11 consecutive dominant bits have been detected and discards all the other bits received.

# 10.7.10 LIN Mode Register Description STATUS REGISTER (SCISR)

Read Only Reset Value: 1100 0000 (C0h)

7							0
TDRE	тс	RDRF	IDLE	LHE	NF	FE	PE

Bits 7:4 = Same function as in SCI mode, please refer to Section 0.1.8 SCI Mode Register Description.

#### Bit 3 = LHE LIN Header Error.

During LIN Header this bit signals three error types:

- The LIN Synch Field is corrupted and the SCI is blocked in LIN Synch State (LSF bit = 1).
- A timeout occurred during LIN Header reception
- An overrun error was detected on one of the header field (see OR bit description in Section 0.1.8 SCI Mode Register Description)).

An interrupt is generated if RIE = 1 in the SCICR2 register. If blocked in the LIN Synch State, the LSF bit must first be reset (to exit LIN Synch Field state and then to be able to clear LHE flag). Then it is cleared by the following software sequence: An access to the SCISR register followed by a read to the SCIDR register.

0: No LIN Header error

1: LIN Header error detected

#### Note:

Apart from the LIN Header this bit signals an Overrun Error as in SCI mode, (see description in Section 0.1.8 SCI Mode Register Description)

#### Bit 2 = NF Noise flag

In LIN Master mode (LINE bit = 1 and LSLV bit = 0) this bit has the same function as in SCI mode, please refer to Section 0.1.8 SCI Mode Register Description

In LIN Slave mode (LINE bit = 1 and LSLV bit = 1) this bit has no meaning.

#### Bit 1 = **FE** Framing error.

In LIN slave mode, this bit is set only when a real

framing error is detected (if the stop bit is dominant (0) and at least one of the other bits is recessive (1). It is not set when a break occurs, the LHDF bit is used instead as a break flag (if the LHDM bit = 0). It is cleared by a software sequence (an access to the SCISR register followed by a read to the SCIDR register).

0: No Framing error 1: Framing error detected

# Bit 0 = **PE** Parity error.

This bit is set by hardware when a LIN parity error occurs (if the PCE bit is set) in receiver mode. It is cleared by a software sequence (a read to the status register followed by an access to the SCIDR data register). An interrupt is generated if PIE = 1 in the SCICR1 register.

0: No LIN parity error

1: LIN Parity error detected

Bits 7:2 Same function as in SCI mode, please refer to Section 0.1.8 SCI Mode Register Description.

#### Bit 1 = **RWU** Receiver wake-up.

This bit determines if the SCI is in mute mode or not. It is set and cleared by software and can be cleared by hardware when a wake-up sequence is recognized.

0: Receiver in active mode

1: Receiver in mute mode

#### Notes:

- Mute mode is recommended for detecting only the Header and avoiding the reception of any other characters. For more details please refer to Section 0.1.9.3 LIN Reception.
- In LIN slave mode, when RDRF is set, the software can not set or clear the RWU bit.

#### Bit 0 = **SBK** Send break.

This bit set is used to send break characters. It is set and cleared by software.

0: No break character is transmitted

1: Break characters are transmitted

**Note:** If the SBK bit is set to "1" and then to "0", the transmitter will send a BREAK word at the end of the current word.

# **CONTROL REGISTER 3 (SCICR3)**

LSF

# Bit 7 = LDUM LIN Divider Update Method.

This bit is set and cleared by software and is also cleared by hardware (when RDRF = 1). It is only used in LIN Slave mode. It determines how the LIN Divider can be updated by software.

LHIE

LHDF

0: LDIV is updated as soon as LPR is written (if no Auto Synchronization update occurs at the same time).

1: LDIV is updated at the next received character (when RDRF = 1) after a write to the LPR register

#### Notes:

- If no write to LPR is performed between the setting of LDUM bit and the reception of the next character, LDIV will be updated with the old value.

- After LDUM has been set, it is possible to reset the LDUM bit by software. In this case, LDIV can be modified by writing into LPR / LPFR registers.

Bits 6:5 = **LINE**, **LSLV** *LIN Mode Enable Bits*. These bits configure the LIN mode:

LINE	LSLV	Meaning
0	х	LIN mode disabled
4	0	LIN Master Mode
1	1	LIN Slave Mode

The LIN Master configuration enables:

The capability to send LIN Synch Breaks (13 low bits) using the SBK bit in the SCICR2 register.

- The LIN Slave configuration enables:
  - The LIN Slave Baud Rate generator. The LIN Divider (LDIV) is then represented by the LPR and LPFR registers. The LPR and LPFR registers are read/write accessible at the address of the SCIBRR register and the address of the SCIETPR register
  - Management of LIN Headers.
  - LIN Synch Break detection (11-bit dominant).
  - LIN Wake-Up method (see LHDM bit) instead of the normal SCI Wake-Up method.
  - Inhibition of Break transmission capability (SBK has no effect)
  - LIN Parity Checking (in conjunction with the PCE bit)

#### Bit 4 = **LASE** *LIN Auto Synch Enable*.

This bit enables the Auto Synch Unit (ASU). It is set and cleared by software. It is only usable in LIN Slave mode.

0: Auto Synch Unit disabled

1: Auto Synch Unit enabled.

#### Bit 3 = **LHDM** *LIN Header Detection Method* This bit is set and cleared by software. It is only usable in LIN Slave mode. It enables the Header Detection Method. In addition if the RWU bit in the

# LINSCI™ SERIAL COMMUNICATION INTERFACE (LIN Mode) (Cont'd)

SCICR2 register is set, the LHDM bit selects the Wake-Up method (replacing the WAKE bit). 0: LIN Synch Break Detection Method 1: LIN Identifier Field Detection Method

#### Bit 2 = LHIE LIN Header Interrupt Enable

This bit is set and cleared by software. It is only usable in LIN Slave mode.

0: LIN Header Interrupt is inhibited.

1: An SCI interrupt is generated whenever LHDF = 1.

#### Bit 1 = LHDF LIN Header Detection Flag

This bit is set by hardware when a LIN Header is detected and cleared by a software sequence (an access to the SCISR register followed by a read of the SCICR3 register). It is only usable in LIN Slave mode.

0: No LIN Header detected.

1: LIN Header detected.

**Notes:** The header detection method depends on the LHDM bit:

- If LHDM = 0, a header is detected as a LIN Synch Break.
- If LHDM = 1, a header is detected as a LIN Identifier, meaning that a LIN Synch Break Field + a LIN Synch Field + a LIN Identifier Field have been consecutively received.

#### Bit 0 = LSF LIN Synch Field State

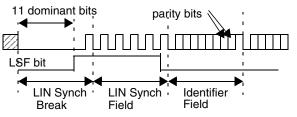

This bit indicates that the LIN Synch Field is being analyzed. It is only used in LIN Slave mode. In Auto Synchronization Mode (LASE bit = 1), when the SCI is in the LIN Synch Field State it waits or counts the falling edges on the RDI line.

It is set by hardware as soon as a LIN Synch Break is detected and cleared by hardware when the LIN Synch Field analysis is finished (See Figure 11). This bit can also be cleared by software to exit LIN Synch State and return to idle mode.

0: The current character is not the LIN Synch Field

1: LIN Synch Field State (LIN Synch Field undergoing analysis)

#### Figure 87. LSF Bit Set and Clear

#### LIN DIVIDER REGISTERS

LDIV is coded using the two registers LPR and LP-FR. In LIN Slave mode, the LPR register is accessible at the address of the SCIBRR register and the LPFR register is accessible at the address of the SCIETPR register.

#### LIN PRESCALER REGISTER (LPR)

#### **Read/Write**

Reset Value: 0000 0000 (00h)

7							0
LPR7	LPR6	LPR5	LPR4	LPR3	LPR2	LPR1	LPR0

#### **LPR[7:0]** *LIN Prescaler (mantissa of LDIV)*

These 8 bits define the value of the mantissa of the LIN Divider (LDIV):

LPR[7:0]	Rounded Mantissa (LDIV)
00h	SCI clock disabled
01h	1
FEh	254
FFh	255

**Caution:** LPR and LPFR registers have different meanings when reading or writing to them. Consequently bit manipulation instructions (BRES or BSET) should never be used to modify the LPR[7:0] bits, or the LPFR[3:0] bits.

#### LINSCI™ SERIAL COMMUNICATION INTERFACE (LIN Mode) (Cont'd) LIN PRESCALER FRACTION REGISTER will effectively upda

(LPFR)

Read/Write

Reset Value: 0000 0000 (00h)

7							0
0	0	0	0	LPFR 3	LPFR 2	LPFR 1	LPFR 0

Bits 7:4 = Reserved.

#### Bits 3:0 = LPFR[3:0] Fraction of LDIV

These 4 bits define the fraction of the LIN Divider (LDIV):

LPFR[3:0]	Fraction (LDIV)
0h	0
1h	1/16
Eh	14/16
Fh	15/16

1. When initializing LDIV, the LPFR register must be written first. Then, the write to the LPR register

will effectively update LDIV and so the clock generation.

2. In LIN Slave mode, if the LPR[7:0] register is equal to 00h, the transceiver and receiver input clocks are switched off.

#### Examples of LDIV coding:

Example 1: LPR = 27d and LPFR = 12d This leads to: Mantissa (LDIV) = 27d Fraction (LDIV) = 12/16 = 0.75dTherefore LDIV = 27.75d

Example 2: LDIV = 25.62dThis leads to: LPFR = rounded(16\*0.62d) = rounded(9.92d) = 10d = Ah LPR = mantissa (25.620d) = 25d = 1Bh

Example 3: LDIV = 25.99d This leads to: LPFR = rounded(16\*0.99d) = rounded(15.84d) = 16d

# LINSCI™ SERIAL COMMUNICATION INTERFACE (LIN Mode) (Cont'd)

# LIN HEADER LENGTH REGISTER (LHLR)

Read Only Reset Value: 0000 0000 (00h).

7							0
LHL7	LHL6	LHL5	LHL4	LHL3	LHL2	LHL1	LHLO

**Note:** In LIN Slave mode when LASE = 1 or LHDM = 1, the LHLR register is accessible at the address of the SCIERPR register.

Otherwise this register is always read as 00h.

# Bits 7:0 = LHL[7:0] LIN Header Length.

This is a read-only register, which is updated by hardware if one of the following conditions occurs: - After each break detection, it is loaded with "FFh".

- If a timeout occurs on  $T_{\mbox{\scriptsize HEADER}},$  it is loaded with 00h.

- After every successful LIN Header reception (at the same time than the setting of LHDF bit), it is loaded with a value (LHL) which gives access to the number of bit times of the LIN header length ( $T_{HEADER}$ ). The coding of this value is explained below:

# LHL Coding:

 $T_{HEADER_{MAX}} = 57$ 

LHL(7:2) represents the mantissa of (57 -  $T_{HEAD-ER}$ )

LHL(1:0) represents the fraction (57 -  $T_{HEADER}$ )

LHL[7:2]	Mantissa (57 - T <sub>HEADER</sub> )	Mantissa (T <sub>HEADER</sub> )
0h	0	57
1h	1	56
39h	56	1
3Ah	57	0
3Bh	58	Never Occurs
3Eh	62	Never Occurs
3Fh	63	Initial value

LHL[1:0]	Fraction (57 - T <sub>HEADER</sub> )
0h	0
1h	1/4
2h	1/2
3h	3/4

# Example of LHL coding:

Example 1: LHL =  $33h = 001100 \ 11b$ LHL(7:3) = 1100b = 12dLHL(1:0) = 11b = 3dThis leads to: Mantissa (57 - T<sub>HEADER</sub>) = 12dFraction (57 - T<sub>HEADER</sub>) = 3/4 = 0.75Therefore: (57 - T<sub>HEADER</sub>) = 12.75dand T<sub>HEADER</sub> = 44.25d

Example 2:

 $\begin{array}{l} 57 \ \ - \ \ T_{HEADER} = 36.21d \\ LHL(1:0) = rounded(4^{*}0.21d) = 1d \\ LHL(7:2) = Mantissa \ (36.21d) = 36d = 24h \\ Therefore \ LHL(7:0) = 10010001 = 91h \end{array}$ 

Example 3:

 $57 - T_{HEADER} = 36.90d$ LHL(1:0) = rounded(4\*0.90d) = 4d The carry must be propagated to the matissa: LHL(7:2) = Mantissa (36.90d) + 1 = 37d = Therefore LHL(7:0) = 10110000 = A0h

# 10.8 LINSCI SERIAL COMMUNICATION INTERFACE (LIN Master Only)

#### 10.8.1 Introduction

The Serial Communications Interface (SCI) offers a flexible means of full-duplex data exchange with external equipment requiring an industry standard NRZ asynchronous serial data format. The SCI offers a very wide range of baud rates using two baud rate generator systems.

#### 10.8.2 Main Features

- Full duplex, asynchronous communications
- NRZ standard format (Mark/Space)
- Dual baud rate generator systems
- Independently programmable transmit and receive baud rates up to 500K baud.
- Programmable data word length (8 or 9 bits)
- Receive buffer full, Transmit buffer empty and End of Transmission flags
- 2 receiver wake-up modes:
  - Address bit (MSB)
  - Idle line
- Muting function for multiprocessor configurations
- Separate enable bits for Transmitter and Receiver
- 4 error detection flags:
  - Overrun error
  - Noise error
  - Frame error
  - Parity error
- 5 interrupt sources with flags:
  - Transmit data register empty
  - Transmission complete
  - Receive data register full
  - Idle line received
  - Overrun error detected
- Transmitter clock output
- Parity control:
  - Transmits parity bit
  - Checks parity of received data byte
- Reduced power consumption mode
- LIN Synch Break send capability

#### **10.8.3 General Description**

The interface is externally connected to another device by three pins (see Figure 1 on page 19). Any SCI bidirectional communication requires a minimum of two pins: Receive Data In (RDI) and Transmit Data Out (TDO):

- SCLK: Transmitter clock output. This pin outputs the transmitter data clock for synchronous transmission (no clock pulses on start bit and stop bit, and a software option to send a clock pulse on the last data bit). This can be used to control peripherals that have shift registers (e.g. LCD drivers). The clock phase and polarity are software programmable.
- TDO: Transmit Data Output. When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and nothing is to be transmitted, the TDO pin is at high level.
- RDI: Receive Data Input is the serial data input. Oversampling techniques are used for data recovery by discriminating between valid incoming data and noise.

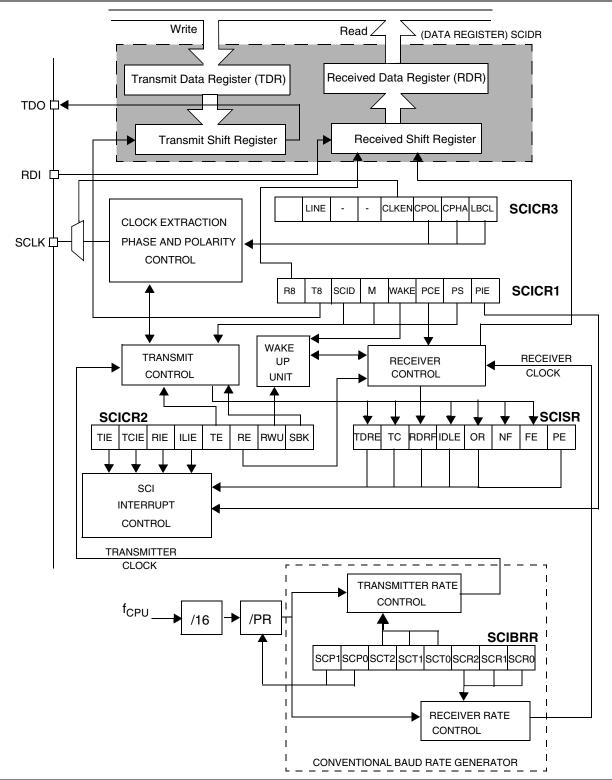

Through these pins, serial data is transmitted and received as frames comprising:

- An Idle Line prior to transmission or reception
- A start bit
- A data word (8 or 9 bits) least significant bit first
- A Stop bit indicating that the frame is complete.
- This interface uses two types of baud rate generator:
- A conventional type for commonly-used baud rates,
- An extended type with a prescaler offering a very wide range of baud rates even with non-standard oscillator frequencies.

#### Figure 88. SCI Block Diagram

57

## **10.8.4 Functional Description**

The block diagram of the Serial Control Interface, is shown in Figure 1 on page 19. It contains seven dedicated registers:

- Three control registers (SCICR1, SCICR2 and SCICR3)
- A status register (SCISR)
- A baud rate register (SCIBRR)
- An extended prescaler receiver register (SCIER-PR)
- An extended prescaler transmitter register (SCI-ETPR)

Refer to the register descriptions in Section 0.1.8 for the definitions of each bit.

# 10.8.4.1 Serial Data Format

Word length may be selected as being either 8 or 9 bits by programming the M bit in the SCICR1 register (see Figure 2).

The TDO pin is in low state during the start bit.

The TDO pin is in high state during the stop bit.

An Idle character is interpreted as an entire frame of "1"s followed by the start bit of the next frame which contains data.

A Break character is interpreted on receiving "0"s for some multiple of the frame period. At the end of the last break frame the transmitter inserts an extra "1" bit to acknowledge the start bit.

Transmission and reception are driven by their own baud rate generator.

CLOC	BR III III III	Possible Parity Bit Bit7 Bit8 St B	Next Data Frame Next op Start Bit

	Idle Frame		Start Bit Extra Start
			controls last data clock pulse

# Figure 89. Word Length Programming

#### 10.8.4.2 Transmitter

The transmitter can send data words of either 8 or 9 bits depending on the M bit status. When the M bit is set, word length is 9 bits and the 9th bit (the MSB) has to be stored in the T8 bit in the SCICR1 register.

When the transmit enable bit (TE) is set, the data in the transmit shift register is output on the TDO pin and the corresponding clock pulses are output on the SCLK pin.

#### **Character Transmission**

During an SCI transmission, data shifts out least significant bit first on the TDO pin. In this mode, the SCIDR register consists of a buffer (TDR) between the internal bus and the transmit shift register (see Figure 2).

#### Procedure

5/

- Select the M bit to define the word length.
- Select the desired baud rate using the SCIBRR and the SCIETPR registers.
- Set the TE bit to send an idle frame as first transmission.
- Access the SCISR register and write the data to send in the SCIDR register (this sequence clears the TDRE bit). Repeat this sequence for each data to be transmitted.

Clearing the TDRE bit is always performed by the following software sequence:

- 1. An access to the SCISR register
- 2. A write to the SCIDR register

The TDRE bit is set by hardware and it indicates:

- The TDR register is empty.
- The data transfer is beginning.
- The next data can be written in the SCIDR register without overwriting the previous data.

This flag generates an interrupt if the TIE bit is set and the I bit is cleared in the CCR register.

When a transmission is taking place, a write instruction to the SCIDR register stores the data in the TDR register and which is copied in the shift register at the end of the current transmission.

When no transmission is taking place, a write instruction to the SCIDR register places the data directly in the shift register, the data transmission starts, and the TDRE bit is immediately set. When a frame transmission is complete (after the stop bit or after the break frame) the TC bit is set and an interrupt is generated if the TCIE is set and the I bit is cleared in the CCR register.

Clearing the TC bit is performed by the following software sequence:

1. An access to the SCISR register

2. A write to the SCIDR register

**Note:** The TDRE and TC bits are cleared by the same software sequence.

#### **Break Characters**

Setting the SBK bit loads the shift register with a break character. The break frame length depends on the M bit (see Figure 2).

As long as the SBK bit is set, the SCI send break frames to the TDO pin. After clearing this bit by software the SCI insert a logic 1 bit at the end of the last break frame to guarantee the recognition of the start bit of the next frame.

#### **Idle Characters**

Setting the TE bit drives the SCI to send an idle frame before the first data frame.

Clearing and then setting the TE bit during a transmission sends an idle frame after the current word.

**Note:** Resetting and setting the TE bit causes the data in the TDR register to be lost. Therefore the best time to toggle the TE bit is when the TDRE bit is set, that is, before writing the next byte in the SCIDR.

#### **LIN Transmission**

The same procedure has to be applied for LIN Master transmission with the following differences:

- Clear the M bit to configure 8-bit word length.
- Set the LINE bit to enter LIN master mode. In this case, setting the SBK bit sends 13 low bits.

#### 10.8.4.3 Receiver

The SCI can receive data words of either 8 or 9 bits. When the M bit is set, word length is 9 bits and the MSB is stored in the R8 bit in the SCICR1 register.

#### **Character reception**

During a SCI reception, data shifts in least significant bit first through the RDI pin. In this mode, the SCIDR register consists or a buffer (RDR) between the internal bus and the received shift register (see Figure 1 on page 19).

#### Procedure

- Select the M bit to define the word length.
- Select the desired baud rate using the SCIBRR and the SCIERPR registers.
- Set the RE bit, this enables the receiver which begins searching for a start bit.

When a character is received:

- The RDRF bit is set. It indicates that the content of the shift register is transferred to the RDR.
- An interrupt is generated if the RIE bit is set and the I bit is cleared in the CCR register.
- The error flags can be set if a frame error, noise or an overrun error has been detected during reception.

Clearing the RDRF bit is performed by the following software sequence done by:

- 1. An access to the SCISR register
- 2. A read to the SCIDR register.

The RDRF bit must be cleared before the end of the reception of the next character to avoid an overrun error.

#### **Break Character**

When a break character is received, the SCI handles it as a framing error.

#### **Idle Character**

When an idle frame is detected, there is the same procedure as a data received character plus an interrupt if the ILIE bit is set and the I bit is cleared in the CCR register.

#### **Overrun Error**

An overrun error occurs when a character is received when RDRF has not been reset. Data cannot be transferred from the shift register to the RDR register until the RDRF bit is cleared.

When a overrun error occurs:

- The OR bit is set.
- The RDR content is not lost.
- The shift register is overwritten.
- An interrupt is generated if the RIE bit is set and the I bit is cleared in the CCR register.

The OR bit is reset by an access to the SCISR register followed by a SCIDR register read operation.

#### Noise Error

Oversampling techniques are used for data recovery by discriminating between valid incoming data and noise.

When noise is detected in a frame:

- The NF is set at the rising edge of the RDRF bit.
- Data is transferred from the Shift register to the SCIDR register.
- No interrupt is generated. However this bit rises at the same time as the RDRF bit which itself generates an interrupt.

The NF bit is reset by a SCISR register read operation followed by a SCIDR register read operation.

#### **Framing Error**

A framing error is detected when:

- The stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.
- A break is received.

When the framing error is detected:

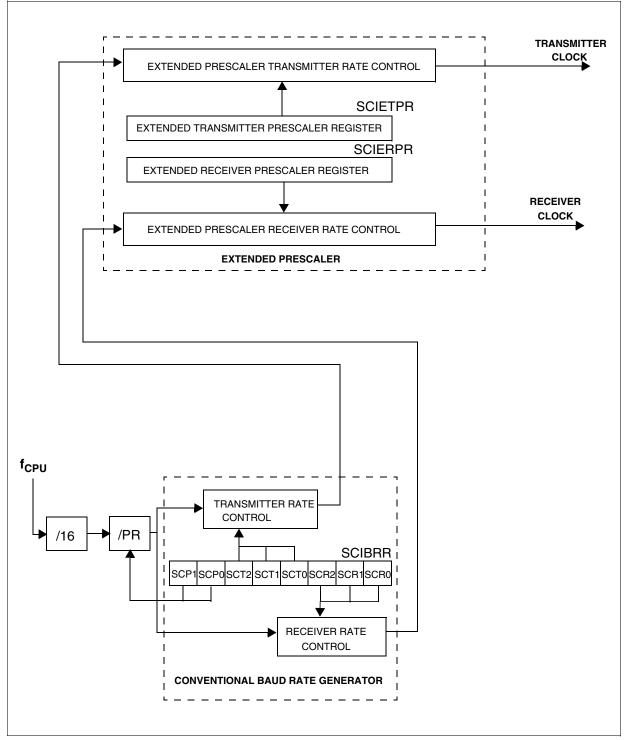

- the FE bit is set by hardware
- Data is transferred from the Shift register to the SCIDR register.
- No interrupt is generated. However this bit rises at the same time as the RDRF bit which itself generates an interrupt.

The FE bit is reset by a SCISR register read operation followed by a SCIDR register read operation.

#### Figure 90. SCI Baud Rate and Extended Prescaler Block Diagram

57

#### 10.8.4.4 Conventional Baud Rate Generation

The baud rates for the receiver and transmitter (Rx and Tx) are set independently and calculated as follows

2

 $Tx = \frac{f_{CPU}}{(16*PR)*TR}$ 

with:

PR = 1, 3, 4 or 13 (see SCP[1:0] bits)

TR = 1, 2, 4, 8, 16, 32, 64, 128

(see SCT[2:0] bits)

RR = 1, 2, 4, 8, 16, 32, 64, 128

(see SCR[2:0] bits)

All these bits are in the SCIBRR register.

**Example:** If  $f_{CPU}$  is 8 MHz (normal mode) and if PR = 13 and TR = RR = 1, the transmit and receive baud rates are 38400 baud.

**Note:** The baud rate registers MUST NOT be changed while the transmitter or the receiver is enabled.

#### 10.8.4.5 Extended Baud Rate Generation

The extended prescaler option gives a very fine tuning on the baud rate, using a 255 value prescaler, whereas the conventional Baud Rate Generator retains industry standard software compatibility.

The extended baud rate generator block diagram is described in the Figure 3.

The output clock rate sent to the transmitter or to the receiver is the output from the 16 divider divided by a factor ranging from 1 to 255 set in the SCI-ERPR or the SCIETPR register.

**Note:** The extended prescaler is activated by setting the SCIETPR or SCIERPR register to a value

other than zero. The baud rates are calculated as follows:

$$Tx = \frac{f_{CPU}}{16 \cdot ETPR^{*}(PR^{*}TR)} Rx = \frac{f_{CPU}}{16 \cdot ERPR^{*}(PR^{*}RR)}$$

with:

ETPR = 1, ..., 255 (see SCIETPR register)

ERPR = 1, ..., 255 (see SCIERPR register)

#### 10.8.4.6 Receiver Muting and Wake-up Feature

In multiprocessor configurations it is often desirable that only the intended message recipient should actively receive the full message contents, thus reducing redundant SCI service overhead for all non addressed receivers.

The non addressed devices may be placed in sleep mode by means of the muting function.

Setting the RWU bit by software puts the SCI in sleep mode:

All the reception status bits cannot be set.

All the receive interrupts are inhibited.

A muted receiver may be awakened by one of the following two ways:

- by Idle Line detection if the WAKE bit is reset,

- by Address Mark detection if the WAKE bit is set.

Receiver wakes-up by Idle Line detection when the Receive line has recognized an Idle Frame. Then the RWU bit is reset by hardware but the IDLE bit is not set.

Receiver wakes-up by Address Mark detection when it received a "1" as the most significant bit of a word, thus indicating that the message is an address. The reception of this particular word wakes up the receiver, resets the RWU bit and sets the RDRF bit, which allows the receiver to receive this word normally and to use it as an address word.

#### 10.8.4.7 Parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the SCICR1 register. Depending on the frame length defined by the M bit, the possible SCI frame formats are as listed in Table 1.

M bit	PCE bit	SCI frame
0	0	SB   8 bit data   STB
0	1	SB   7-bit data   PB   STB
1	0	SB   9-bit data   STB
I	1	SB   8-bit data PB   STB

#### Table 24. Frame Formats

#### Legend:

SB: Start Bit

STB: Stop Bit

**PB:** Parity Bit

**Note**: In case of wake up by an address mark, the MSB bit of the data is taken into account and not the parity bit

**Even parity:** The parity bit is calculated to obtain an even number of "1s" inside the frame made of the 7 or 8 LSB bits (depending on whether M is equal to 0 or 1) and the parity bit.

Example: data = 00110101; 4 bits set => parity bit is 0 if even parity is selected (PS bit = 0).

**<u>Odd parity:</u>** The parity bit is calculated to obtain an odd number of "1s" inside the frame made of the 7 or 8 LSB bits (depending on whether M is equal to 0 or 1) and the parity bit.

Example: data = 00110101; 4 bits set => parity bit is 1 if odd parity is selected (PS bit = 1).

**Transmission mode:** If the PCE bit is set then the MSB bit of the data written in the data register is not transmitted but is changed by the parity bit.

**<u>Reception mode:</u>** If the PCE bit is set then the interface checks if the received data byte has an

even number of "1s" if even parity is selected (PS = 0) or an odd number of "1s" if odd parity is selected (PS = 1). If the parity check fails, the PE flag is set in the SCISR register and an interrupt is generated if PIE is set in the SCICR1 register.

#### 10.8.5 Low Power Modes

Mode	Description
	No effect on SCI.
WAIT	SCI interrupts cause the device to exit from Wait mode.
	SCI registers are frozen.
HALT	In Halt mode, the SCI stops transmitting/re- ceiving until Halt mode is exited.

#### 10.8.6 Interrupts

Interrupt Event	Event Flag	Enable Control Bit	Exit from Wait	Exit from Halt
Transmit Data Register Empty	TDRE	TIE		
Transmission Com- plete	тс	TCIE		
Received Data Ready to be Read	RDRF	RIE	Yes	No
Overrun Error Detect- ed	OR	111		
Idle Line Detected	IDLE	ILIE		
Parity Error	PE	PIE		

The SCI interrupt events are connected to the same interrupt vector.

These events generate an interrupt if the corresponding Enable Control Bit is set and the interrupt mask in the CC register is reset (RIM instruction).

#### 10.8.7 SCI Synchronous Transmission

The SCI transmitter allows the user to control a one way synchronous serial transmission. The SCLK pin is the output of the SCI transmitter clock. No clock pulses are sent to the SCLK pin during start bit and stop bit. Depending on the state of the LBCL bit in the SCICR3 register, clock pulses are or are not be generated during the last valid data bit (address mark). The CPOL bit in the SCICR3 register allows the user to select the clock polarity, and the CPHA bit in the SCICR3 register allows the user to select the phase of the external clock (see Figure 4, Figure 5 and Figure 6).

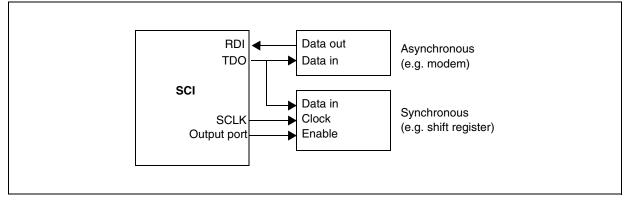

During idle, preamble and send break, the external SCLK clock is not activated.

These options allow the user to serially control peripherals which consist of shift registers, without losing any functions of the SCI transmitter which can still talk to other SCI receivers. These options do not affect the SCI receiver which is independent from the transmitter.

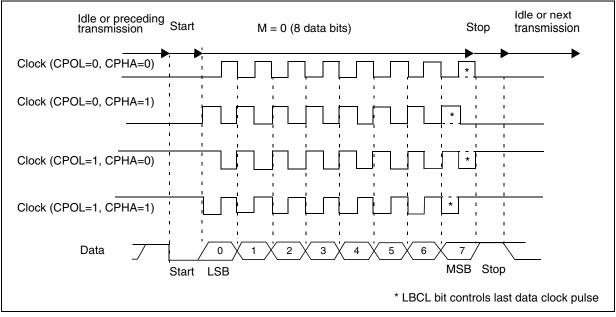

**Note:** The SCLK pin works in conjunction with the TDO pin. When the SCI transmitter is disabled (TE and RE = 0), the SCLK and TDO pins go into high impedance state.

**Note:** The LBCL, CPOL and CPHA bits have to be selected before enabling the transmitter to ensure that the clock pulses function correctly. These bits should not be changed while the transmitter is enabled.

47/

# Figure 93. SCI Data Clock Timing Diagram (M = 1)

57/

# 10.8.8 Register Description STATUS REGISTER (SCISR)

Read Only

Reset Value: 1100 0000 (C0h)

7							0
TDRE	тс	RDRF	IDLE	OR	NF	FE	PE

#### Bit 7 = **TDRE** *Transmit data register empty.*

This bit is set by hardware when the content of the TDR register has been transferred into the shift register. An interrupt is generated if the TIE bit = 1 in the SCICR2 register. It is cleared by a software sequence (an access to the SCISR register followed by a write to the SCIDR register).

0: Data is not transferred to the shift register

1: Data is transferred to the shift register

**Note**: Data is not be transferred to the shift register until the TDRE bit is cleared.

#### Bit 6 = TC Transmission complete.

This bit is set by hardware when transmission of a frame containing Data is complete. An interrupt is generated if TCIE = 1 in the SCICR2 register. It is cleared by a software sequence (an access to the SCISR register followed by a write to the SCIDR register).

0: Transmission is not complete

1: Transmission is complete

**Note:** TC is not set after the transmission of a Preamble or a Break.

#### Bit 5 = **RDRF** *Received data ready flag.*

This bit is set by hardware when the content of the RDR register has been transferred to the SCIDR register. An interrupt is generated if RIE = 1 in the SCICR2 register. It is cleared by a software sequence (an access to the SCISR register followed by a read to the SCIDR register).

0: Data is not received

1: Received data is ready to be read

#### Bit 4 = **IDLE** *Idle line detect.*

This bit is set by hardware when an Idle Line is detected. An interrupt is generated if the ILIE = 1 in the SCICR2 register. It is cleared by a software sequence (an access to the SCISR register followed by a read to the SCIDR register).

0: No Idle Line is detected

1: Idle Line is detected

**Note:** The IDLE bit is not be set again until the RDRF bit has been set itself (that is, a new idle line occurs).

#### Bit 3 = **OR** Overrun error.

This bit is set by hardware when the word currently being received in the shift register is ready to be transferred into the RDR register while RDRF = 1. An interrupt is generated if RIE = 1 in the SCICR2 register. It is cleared by a software sequence (an access to the SCISR register followed by a read to the SCIDR register).

0: No Overrun error

1: Overrun error is detected

**Note:** When this bit is set, the RDR register content is not lost but the shift register is overwritten.

#### Bit 2 = NF Noise flag.

This bit is set by hardware when noise is detected on a received frame. It is cleared by a software sequence (an access to the SCISR register followed by a read to the SCIDR register).

0: No noise is detected

1: Noise is detected

**Note:** This bit does not generate interrupt as it appears at the same time as the RDRF bit which itself generates an interrupt.

#### Bit 1 = **FE** Framing error.

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by a software sequence (an access to the SCISR register followed by a read to the SCIDR register).

0: No Framing error is detected

1: Framing error or break character is detected

**Note:** This bit does not generate an interrupt as it appears at the same time as the RDRF bit which itself generates an interrupt. If the word currently being transferred causes both frame error and overrun error, it is transferred and only the OR bit is set.

#### Bit 0 = PE Parity error.

This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by a software sequence (a read to the status register followed by an access to the SCIDR data register). An interrupt is generated if PIE = 1 in the SCICR1 register. 0: No parity error

1: Parity error

# LINSCI™ SERIAL COMMUNICATION INTERFACE (LIN Master Only) (Cont'd) CONTROL REGISTER 1 (SCICR1)

#### Read/Write

Reset Value: x000 0000 (x0h)

7							0
R8	Т8	SCID	М	WAKE	PCE	PS	PIE

#### Bit 7 = **R8** Receive data bit 8.

This bit is used to store the 9th bit of the received word when M = 1.

#### Bit 6 = **T8** *Transmit data bit 8.*

This bit is used to store the 9th bit of the transmitted word when M = 1.

Bit 5 = **SCID** *Disabled for low power consumption* When this bit is set the SCI prescalers and outputs are stopped and the end of the current byte transfer in order to reduce power consumption. This bit is set and cleared by software.

0: SCI enabled

1: SCI prescaler and outputs disabled

Bit  $4 = \mathbf{M}$  Word length. This bit determines the word length. It is set or cleared by software.

0: 1 Start bit, 8 Data bits, 1 Stop bit

1: 1 Start bit, 9 Data bits, 1 Stop bit

**Note**: The M bit must not be modified during a data transfer (both transmission and reception).

#### Bit 3 = **WAKE** *Wake-Up method.*

This bit determines the SCI Wake-Up method, it is set or cleared by software. 0: Idle Line

1: Address Mark

#### Bit 2 = **PCE** Parity control enable.

This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M = 1; 8th bit if M = 0) and parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).

0: Parity control disabled

1: Parity control enabled

#### Bit 1 = **PS** Parity selection.

This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.

0: Even parity

1: Odd parity

#### Bit 0 = **PIE** *Parity interrupt enable.*

This bit enables the interrupt capability of the hardware parity control when a parity error is detected (PE bit set). It is set and cleared by software.

0: Parity error interrupt disabled

1: Parity error interrupt enabled

# LINSCI™ SERIAL COMMUNICATION INTERFACE (LIN Master Only) (Cont'd) CONTROL REGISTER 2 (SCICR2)

#### Read/Write

Reset Value: 0000 0000 (00h)

7							0
TIE	TCIE	RIE	ILIE	TE	RE	RWU	SBK

Bit 7 = **TIE** *Transmitter interrupt enable.* This bit is set and cleared by software. 0: Interrupt is inhibited

1: An SCI interrupt is generated whenever TDRE = 1 in the SCISR register

Bit 6 = **TCIE** *Transmission complete interrupt enable* 

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An SCI interrupt is generated whenever TC = 1 in the SCISR register

#### Bit 5 = **RIE** Receiver interrupt enable.

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: An SCI interrupt is generated whenever OR = 1 or RDRF = 1 in the SCISR register

#### Bit 4 = **ILIE** *Idle line interrupt enable.*

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An SCI interrupt is generated whenever IDLE = 1 in the SCISR register.

#### Bit 3 = **TE** *Transmitter enable.*

This bit enables the transmitter. It is set and cleared by software. 0: Transmitter is disabled

1: Transmitter is enabled

#### Notes:

- During transmission, a "0" pulse on the TE bit ("0" followed by "1") sends a preamble (idle line) after the current word.
- When TE is set there is a 1 bit-time delay before the transmission starts.

#### Bit 2 = **RE** Receiver enable.

This bit enables the receiver. It is set and cleared by software.

- 0: Receiver is disabled
- 1: Receiver is enabled and begins searching for a start bit

#### Bit 1 = RWU Receiver wake-up.

This bit determines if the SCI is in mute mode or not. It is set and cleared by software and can be cleared by hardware when a wake-up sequence is recognized.

0: Receiver in active mode

1: Receiver in mute mode

#### Notes:

- Before selecting Mute mode (by setting the RWU bit) the SCI must first receive a data byte, otherwise it cannot function in Mute mode with wakeup by Idle line detection.
- In Address Mark Detection Wake-Up configuration (WAKE bit = 1) the RWU bit cannot be modified by software while the RDRF bit is set.

#### Bit 0 = SBK Send break.

This bit set is used to send break characters. It is set and cleared by software.

0: No break character is transmitted

1: Break characters are transmitted

**Note:** If the SBK bit is set to "1" and then to "0", the transmitter sends a BREAK word at the end of the current word.

# LINSCI™ SERIAL COMMUNICATION INTERFACE (LIN Master Only) (Cont'd) CONTROL REGISTER 3 (SCICR3) 0: Steady low value on SCI

#### Read/Write

Reset Value: 0000 0000 (00h)

7							0
-	LINE	-	-	CLKEN	CPOL	СРНА	LBCL

Bit 7 = Reserved, must be kept cleared.

#### Bit 6 = LINE LIN Mode Enable.

This bit is set and cleared by software.

0: LIN Mode disabled

1: LIN Master mode enabled

The LIN Master mode enables the capability to send LIN Synch Breaks (13 low bits) using the SBK bit in the SCICR2 register

.In transmission, the LIN Synch Break low phase duration is shown as below:

LINE	М	Number of low bits sent during a LIN Synch Break
0	0	10
0	1	11
1	0	13
I	1	14

Bits 5:4 = Reserved, forced by hardware to 0. These bits are not used.

#### Bit 3 = CLKEN Clock Enable.

This bit allows the user to enable the SCLK pin. 0: SLK pin disabled 1: SLK pin enabled

#### Bit 2 = **CPOL** Clock Polarity.

This bit allows the user to select the polarity of the clock output on the SCLK pin. It works in conjunction with the CPHA bit to produce the desired clock/data relationship (see Figure 5 and Figure 6).

- 0: Steady low value on SCLK pin outside transmission window.
- 1: Steady high value on SCLK pin outside transmission window.

#### Bit 1 = CPHA Clock Phase.

This bit allows the user to select the phase of the clock output on the SCLK pin. It works in conjunction with the CPOL bit to produce the desired clock/data relationship (see Figure 5 and Figure 6) 0: SCLK clock line activated in middle of data bit.

1: SCLK clock line activated at beginning of data bit.

#### Bit 0 = LBCL Last bit clock pulse.

This bit allows the user to select whether the clock pulse associated with the last data bit transmitted (MSB) has to be output on the SCLK pin.

- 0: The clock pulse of the last data bit is not output to the SCLK pin.
- 1: The clock pulse of the last data bit is output to the SCLK pin.

**Note:** The last bit is the 8th or 9th data bit transmitted depending on the 8 or 9 bit format selected by the M bit in the SCICR1 register.

#### Table 25. SCI clock on SCLK pin

Data format	M bit	LBCL bit	Number of clock pulses on SCLK
8 bit	0	0	7
0 Dit	0	1	8
9 bit	1	0	8
9 Dit	I	1	9

**Note:** These 3 bits (**CPOL**, **CPHA**, **LBCL**) should not be written while the transmitter is enabled.

# DATA REGISTER (SCIDR)

#### Read/Write

#### Reset Value: Undefined

Contains the Received or Transmitted data character, depending on whether it is read from or written to.

7							0
DR7	DR6	DR5	DR4	DR3	DR2	DR1	DR0

The Data register performs a double function (read and write) since it is composed of two registers, one for transmission (TDR) and one for reception (RDR).

The TDR register provides the parallel interface between the internal bus and the output shift register (see Figure 1 on page 19).

The RDR register provides the parallel interface between the input shift register and the internal bus (see Figure 1).

# **BAUD RATE REGISTER (SCIBRR)**

Read/Write

Reset Value: 0000 0000 (00h)

# 10.9 10-BIT A/D CONVERTER (ADC)

#### 10.9.1 Introduction

The on-chip Analog to Digital Converter (ADC) peripheral is a 10-bit, successive approximation converter with internal sample and hold circuitry. This peripheral has up to 16 multiplexed analog input channels (refer to device pin out description) that allow the peripheral to convert the analog voltage levels from up to 16 different sources.

The result of the conversion is stored in a 10-bit Data Register. The A/D converter is controlled through a Control/Status Register.

# 10.9.2 Main Features

- 10-bit conversion
- Up to 16 channels with multiplexed input
- Linear successive approximation
- Data register (DR) which contains the results
- Conversion complete status flag

Figure 94. ADC Block Diagram

On/off bit (to reduce consumption)

The block diagram is shown in Figure 94.

5/

#### **10.9.3 Functional Description**

#### 10.9.3.1 Digital A/D Conversion Result

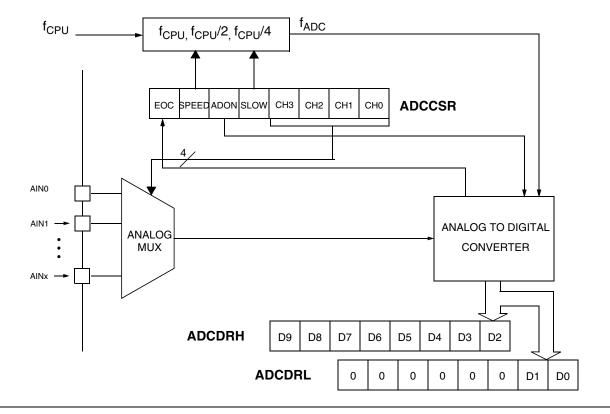

The conversion is monotonic, meaning that the result never decreases if the analog input does not and never increases if the analog input does not.

If the input voltage ( $V_{AIN}$ ) is greater than  $V_{DDA}$ (high-level voltage reference) then the conversion result is FFh in the ADCDRH register and 03h in the ADCDRL register (without overflow indication).

If the input voltage (V<sub>AIN</sub>) is lower than V<sub>SSA</sub> (lowlevel voltage reference) then the conversion result in the ADCDRH and ADCDRL registers is 00 00h.

The A/D converter is linear and the digital result of the conversion is stored in the ADCDRH and AD-CDRL registers. The accuracy of the conversion is described in the Electrical Characteristics Section.

RAIN is the maximum recommended impedance for an analog input signal. If the impedance is too high, this will result in a loss of accuracy due to leakage and sampling not being completed in the allotted time.

# 10-BIT A/D CONVERTER (ADC) (Cont'd)

#### 10.9.3.2 A/D Conversion

The analog input ports must be configured as input, no pull-up, no interrupt. Refer to the "I/O ports" chapter. Using these pins as analog inputs does not affect the ability of the port to be read as a logic input.

In the ADCCSR register:

 Select the CS[3:0] bits to assign the analog channel to convert.

#### ADC Conversion mode

In the ADCCSR register:

 Set the ADON bit to enable the A/D converter and to start the conversion. From this time on, the ADC performs a continuous conversion of the selected channel.

When a conversion is complete:

- The EOC bit is set by hardware.
- The result is in the ADCDR registers.

A read to the ADCDRH resets the EOC bit.

To read the 10 bits, perform the following steps:

- 1. Poll EOC bit
- 2. Read the ADCDRL register
- 3. Read the ADCDRH register. This clears EOC automatically.

To read only 8 bits, perform the following steps:

- 1. Poll EOC bit
- 2. Read the ADCDRH register. This clears EOC automatically.

#### 10.9.3.3 Changing the conversion channel

The application can change channels during conversion. When software modifies the CH[3:0] bits

in the ADCCSR register, the current conversion is stopped, the EOC bit is cleared, and the A/D converter starts converting the newly selected channel.

#### 10.9.3.4 ADCDR consistency

If an End Of Conversion event occurs after software has read the ADCDRLSB but before it has read the ADCDRMSB, there would be a risk that the two values read would belong to different samples.

To guarantee consistency:

- The ADCDRL and the ADCDRH registers are locked when the ADCCRL is read
- The ADCDRL and the ADCDRH registers are unlocked when the ADCDRH register is read or when ADON is reset.

This is important, as the ADCDR register will not be updated until the ADCDRH register is read.

#### 10.9.4 Low Power Modes

**Note:** The A/D converter may be disabled by resetting the ADON bit. This feature allows reduced power consumption when no conversion is needed and between single shot conversions.

Mode	Description
WAIT	No effect on A/D Converter
	A/D Converter disabled.
HALT	After wakeup from Halt mode, the A/D Converter requires a stabilization time t <sub>STAB</sub> (see Electrical Characteristics) before accurate conversions can be performed.

#### 10.9.5 Interrupts

None.

# 10-BIT A/D CONVERTER (ADC) (Cont'd)

#### 10.9.6 Register Description

#### **CONTROL/STATUS REGISTER (ADCCSR)**

Read/Write (Except bit 7 read only)

Reset Value: 0000 0000 (00h)

0 EOC SPEED ADON SLOW СНЗ CH2 CH1 CH0

Bit 7 = **EOC** End of Conversion

This bit is set by hardware. It is cleared by software reading the ADCDRH register or writing to any bit of the ADCCSR register. 0: Conversion is not complete 1: Conversion complete

Bit 6 = SPEED A/D clock selection This bit is set and cleared by software.

#### Table 28. A/D Clock Selection

f <sub>ADC</sub>	SLOW	SPEED
f <sub>CPU</sub> /2	0	0
f <sub>CPU</sub> (where f <sub>CPU</sub> <= 4 MHz)	0	1
f <sub>CPU</sub> /4	1	0
f <sub>CPU</sub> /2 (same frequency as SLOW=0, SPEED=0)	1	1

#### Bit 5 = **ADON** A/D Converter on

This bit is set and cleared by software. 0: Disable ADC and stop conversion 1: Enable ADC and start conversion

#### Bit 4 = SLOW A/D Clock Selection

This bit is set and cleared by software. It works together with the SPEED bit. Refer to Table 28.

#### Bits 3:0 = CH[3:0] Channel Selection

These bits are set and cleared by software. They select the analog input to convert.

\*The number of channels is device dependent. Refer to the device pinout description.

Channel Pin*	СНЗ	CH2	CH1	CH0

# **11 INSTRUCTION SET**

# **11.1 CPU ADDRESSING MODES**

The CPU features 17 different addressing modes which can be classified in seven main groups:

Addressing Mode	Example
Inherent	nop
Immediate	ld A,#\$55
Direct	ld A,\$55
Indexed	ld A,(\$55,X)
Indirect	ld A,([\$55],X)
Relative	jrne loop
Bit operation	bset byte,#5

The CPU Instruction set is designed to minimize the number of bytes required per instruction: To do

Table 30. CPU Addressing Mode Overview

57

so, most of the addressing modes may be subdivided in two submodes called long and short:

- Long addressing mode is more powerful because it can use the full 64 Kbyte address space, however it uses more bytes and more CPU cycles.
- Short addressing mode is less powerful because it can generally only access page zero (0000h -00FFh range), but the instruction size is more compact, and faster. All memory to memory instructions use short addressing modes only (CLR, CPL, NEG, BSET, BRES, BTJT, BTJF, INC, DEC, RLC, RRC, SLL, SRL, SRA, SWAP)

The ST7 Assembler optimizes the use of long and short addressing modes.

	Mode		Syntax	Destination	Pointer Address (Hex.)	Pointer Size (Hex.)	Length (Bytes)
Inherent			nop				+ 0
Immediate			ld A,#\$55				+ 1
Short	Direct		ld A,\$10	00FF			+ 1
Long	Direct		ld A,\$1000	0000FFFF			+ 2
No Offset	Direct	Indexed	ld A,(X)	00FF			+ 0
Short	Direct	Indexed	ld A,(\$10,X)	001FE			+ 1
Long	Direct	Indexed	ld A,(\$1000,X)	0000FFFF			+ 2
Short	Indirect		ld A,[\$10]	00FF	00FF	byte	+ 2
Long	Indirect		ld A,[\$10.w]	0000FFFF	00FF	word	+ 2
Short	Indirect	Indexed	ld A,([\$10],X)	001FE	00FF	byte	+ 2
Long	Indirect	Indexed	ld A,([\$10.w],X)	0000FFFF	00FF	word	+ 2
Relative	Direct		jrne loop	PC+/-127			+ 1
Relative	Indirect		jrne [\$10]	PC+/-127	00FF	byte	+ 2
Bit	Direct		bset \$10,#7	00FF			+ 1
Bit	Indirect		bset [\$10],#7	00FF	00FF	byte	+ 2
Bit	Direct	Relative	btjt \$10,#7,skip	00FF			+ 2
Bit	Indirect	Relative	btjt [\$10],#7,skip	00FF	00FF	byte	+ 3

#### 11.1.1 Inherent

All Inherent instructions consist of a single byte. The opcode fully specifies all the required information for the CPU to process the operation.

Inherent Instruction	Function
NOP	No operation
TRAP	S/W Interrupt
WFI	Wait For Interrupt (Low Pow- er Mode)
HALT	Halt Oscillator (Lowest Power Mode)
RET	Sub-routine Return
IRET	Interrupt Sub-routine Return
SIM	Set Interrupt Mask (level 3)
RIM	Reset Interrupt Mask (level 0)
SCF	Set Carry Flag
RCF	Reset Carry Flag
RSP	Reset Stack Pointer
LD	Load
CLR	Clear
PUSH/POP	Push/Pop to/from the stack
INC/DEC	Increment/Decrement
TNZ	Test Negative or Zero
CPL, NEG	1 or 2 Complement
MUL	Byte Multiplication
SLL, SRL, SRA, RLC, RRC	Shift and Rotate Operations
SWAP	Swap Nibbles

#### 11.1.2 Immediate

Immediate instructions have 2 bytes, the first byte contains the opcode, the second byte contains the operand value.

Immediate Instruction	Function
LD	Load
CP	Compare
BCP	Bit Compare
AND, OR, XOR	Logical Operations
ADC, ADD, SUB, SBC	Arithmetic Operations

#### 11.1.3 Direct

In Direct instructions, the operands are referenced by their memory address.

The direct addressing mode consists of two submodes:

#### **Direct (short)**

The address is a byte, thus requires only one byte after the opcode, but only allows 00 - FF addressing space.

#### Direct (long)

The address is a word, thus allowing 64 Kbyte addressing space, but requires 2 bytes after the opcode.

#### 11.1.4 Indexed (No Offset, Short, Long)

In this mode, the operand is referenced by its memory address, which is defined by the unsigned addition of an index register (X or Y) with an offset.

The indirect addressing mode consists of three submodes:

#### Indexed (No Offset)

There is no offset, (no extra byte after the opcode), and allows 00 - FF addressing space.

#### Indexed (Short)

The offset is a byte, thus requires only one byte after the opcode and allows 00 - 1FE addressing space.

#### Indexed (long)

The offset is a word, thus allowing 64 Kbyte addressing space and requires 2 bytes after the opcode.

#### 11.1.5 Indirect (Short, Long)

The required data byte to do the operation is found by its memory address, located in memory (pointer).

The pointer address follows the opcode. The indirect addressing mode consists of two submodes:

#### Indirect (short)

The pointer address is a byte, the pointer size is a byte, thus allowing 00 - FF addressing space, and requires 1 byte after the opcode.

#### Indirect (long)

The pointer address is a byte, the pointer size is a word, thus allowing 64 Kbyte addressing space, and requires 1 byte after the opcode.

47/

## 11.1.6 Indirect Indexed (Short, Long)

This is a combination of indirect and short indexed addressing modes. The operand is referenced by its memory address, which is defined by the unsigned addition of an index register value (X or Y) with a pointer value located in memory. The pointer address follows the opcode.

The indirect indexed addressing mode consists of two submodes:

#### **Indirect Indexed (Short)**

The pointer address is a byte, the pointer size is a byte, thus allowing 00 - 1FE addressing space, and requires 1 byte after the opcode.

#### Indirect Indexed (Long)

The pointer address is a byte, the pointer size is a word, thus allowing 64 Kbyte addressing space, and requires 1 byte after the opcode.

# Table 31. InstructionsSupportingDirect,Indexed,IndirectandIndirectIndexedAddressing ModesIndirectIndexedIndirect

Long and Short Instructions	Function
LD	Load
CP	Compare
AND, OR, XOR	Logical Operations
ADC, ADD, SUB, SBC	Arithmetic Additions/Sub- stractions operations
BCP	Bit Compare

Short Instructions Only	Function
CLR	Clear
INC, DEC	Increment/Decrement
TNZ	Test Negative or Zero
CPL, NEG	1 or 2 Complement
BSET, BRES	Bit Operations
BTJT, BTJF	Bit Test and Jump Opera- tions
SLL, SRL, SRA, RLC, RRC	Shift and Rotate Operations
SWAP	Swap Nibbles
CALL, JP	Call or Jump subroutine

5/

## 11.1.7 Relative mode (Direct, Indirect)

This addressing mode is used to modify the PC register value, by adding an 8-bit signed offset to it.

Available Relative Direct/Indirect Instructions	Function
JRxx	Conditional Jump
CALLR	Call Relative

The relative addressing mode consists of two submodes:

#### **Relative (Direct)**

The offset is following the opcode.

#### Relative (Indirect)

The offset is defined in memory, which address follows the opcode.

#### **11.2 INSTRUCTION GROUPS**

The ST7 family devices use an Instruction Set consisting of 63 instructions. The instructions may

be subdivided into 13 main groups as illustrated in the following table:

Load and Transfer	LD	CLR						
Stack operation	PUSH	POP	RSP					
Increment/Decrement	INC	DEC						
Compare and Tests	СР	TNZ	BCP					
Logical operations	AND	OR	XOR	CPL	NEG			
Bit Operation	BSET	BRES						
Conditional Bit Test and Branch	BTJT	BTJF						
Arithmetic operations	ADC	ADD	SUB	SBC	MUL			
Shift and Rotates	SLL	SRL	SRA	RLC	RRC	SWAP	SLA	
Unconditional Jump or Call	JRA	JRT	JRF	JP	CALL	CALLR	NOP	RET
Conditional Branch	JRxx							
Interruption management	TRAP	WFI	HALT	IRET				
Condition Code Flag modification	SIM	RIM	SCF	RCF				

#### Using a prebyte

The instructions are described with one to four opcodes.

In order to extend the number of available opcodes for an 8-bit CPU (256 opcodes), three different prebyte opcodes are defined. These prebytes modify the meaning of the instruction they precede.

The whole instruction becomes:

- PC-2 End of previous instruction
- PC-1 Prebyte
- PC Opcode

PC+1 Additional word (0 to 2) according to the number of bytes required to compute the effective address These prebytes enable instruction in Y as well as indirect addressing modes to be implemented. They precede the opcode of the instruction in X or the instruction using direct addressing mode. The prebytes are:

PDY 90 Replace an X based instruction using immediate, direct, indexed, or inherent addressing mode by a Y one.

PIX 92 Replace an instruction using direct, direct bit, or direct relative addressing mode to an instruction using the corresponding indirect addressing mode.

It also changes an instruction using X indexed addressing mode to an instruction using indirect X indexed addressing mode.

PIY 91 Replace an instruction using X indirect indexed addressing mode by a Y one.

57

Mnemo	Description	Function/Example	Dst	Src	11	Н	10	Ν	Z	С
ADC	Add with Carry	A=A+M+C	А	М		н		Ν	Ζ	С
ADD	Addition	A = A + M	А	М		Н		Ν	Ζ	С
AND	Logical And	A = A . M	А	М				Ν	Ζ	
BCP	Bit compare A, Memory	tst (A . M)	А	М				Ν	Ζ	
BRES	Bit Reset	bres Byte, #3	М							
BSET	Bit Set	bset Byte, #3	М							
BTJF	Jump if bit is false (0)	btjf Byte, #3, Jmp1	М							С
BTJT	Jump if bit is true (1)	btjt Byte, #3, Jmp1	М							С

# **12 ELECTRICAL CHARACTERISTICS**

#### **12.1 PARAMETER CONDITIONS**

Unless otherwise specified, all voltages are referred to  $\ensuremath{\mathsf{V}_{SS}}\xspace.$ 

#### 12.1.1 Minimum and Maximum Values

Unless otherwise specified the minimum and maximum values are guaranteed in the worst conditions of ambient temperature, supply voltage and frequencies by tests in production on 100% of the devices with an ambient temperature at  $T_A = 25^{\circ}C$  and  $T_A = T_Amax$  (given by the selected temperature range).

Data based on characterization results, design simulation and/or technology characteristics are indicated in the table footnotes and are not tested in production. Based on characterization, the minimum and maximum values refer to sample tests and represent the mean value plus or minus three times the standard deviation (mean $\pm 3\Sigma$ ).

#### 12.1.2 Typical Values

Unless otherwise specified, typical data is based on  $T_A = 25^{\circ}C$ ,  $V_{DD} = 5V$  (for the  $4.5V \le V_{DD} \le 5.5V$  voltage range). They are given only as design guidelines and are not tested.

Typical ADC accuracy values are determined by characterization of a batch of samples from a standard diffusion lot over the full temperature range, where 95% of the devices have an error less than or equal to the value indicated (mean $\pm 2\Sigma$ ).

#### 12.1.3 Typical Curves

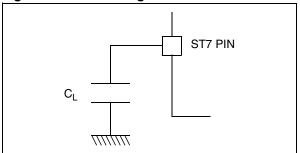

Unless otherwise specified, all typical curves are given only as design guidelines and are not tested.

#### 12.1.4 Loading Capacitor

57/

The loading conditions used for pin parameter measurement are shown in Figure 95.

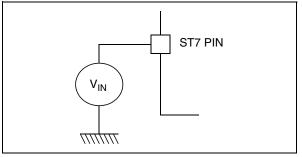

#### Figure 95. Pin Loading Conditions

#### 12.1.5 Pin Input Voltage

The input voltage measurement on a pin of the device is described in Figure 96.

#### Figure 96. Pin input voltage

#### **12.2 ABSOLUTE MAXIMUM RATINGS**

Stresses above those listed as "absolute maximum ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device under these condi-

#### 12.2.1 Voltage Characteristics

tions is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

Symbol	Ratings	Maximum value	Unit	
V <sub>DD</sub> - V <sub>SS</sub>	Supply voltage	6.5		
V <sub>PP</sub> - V <sub>SS</sub>	Programming Voltage	13	V	
V <sub>IN</sub>	Input voltage on any pin <sup>1)2)</sup>	$V_{SS}$ - 0.3 to $V_{DD}$ + 0.3		
$ \Delta V_{DDx} $ and $ \Delta V_{SSx} $	Variations between different digital power pins	50	mV	
V <sub>SSA</sub> - V <sub>SSx</sub>	Variations between digital and analog ground pins	50	IIIV	
V <sub>ESD(HBM)</sub>	Electro-static discharge voltage (Human Body Model)	see Section 12.8.3 on page 19		
V <sub>ESD(MM)</sub>	Electro-static discharge voltage (Machine Model)	- See Section 12.8.3 on page 192		

#### **12.2.2 Current Characteristics**

Symbol	Ratings	Maximum value	Unit	
I <sub>VDD</sub>	Total current into V <sub>DD</sub> power lines (source) <sup>3)</sup>	150		
I <sub>VSS</sub>	Total current out of $V_{SS}$ ground lines (sink) <sup>3)</sup>	150		
	Output current sunk by any standard I/O and control pin	25		
I <sub>IO</sub>	Output current sunk by any high sink I/O pin	50		
	Output current source by any I/Os and control pin	- 25		
	Injected current on V <sub>PP</sub> pin		mA	
	Injected current on RESET pin	± 5		
I <sub>INJ(PIN)</sub> 2)4)	Injected current on OSC1 and OSC2 pins			
	Injected current on PB3 (on Flash devices)	+5		
	Injected current on any other pin <sup>5)</sup>	± 5		
$\Sigma I_{\rm INJ(PIN)}^{2)}$	Total injected current (sum of all I/O and control pins) <sup>5)</sup>	± 25		

#### 12.2.3 Thermal Characteristics

Symbol	Ratings	Value	Unit				
T <sub>STG</sub>	Storage temperature range	-65 to +150	°C				
TJ	Maximum junction temperature (see Section 13.2 "THERMAL CHARACTERISTICS")						

#### Notes:

1. Directly connecting the RESET and I/O pins to V<sub>DD</sub> or V<sub>SS</sub> could damage the device if an unintentional internal reset is generated or an unexpected change of the I/O configuration occurs (for example, due to a corrupted program counter). To guarantee safe operation, this connection has to be done through a pull-up or pull-down resistor (typical: 4.7k $\Omega$  for RESET, 10k $\Omega$  for I/Os). Unused I/O pins must be tied in the same way to V<sub>DD</sub> or V<sub>SS</sub> according to their reset configuration. 2. I<sub>INJ(PIN)</sub> must never be exceeded. This is implicitly insured if V<sub>IN</sub> maximum is respected. If V<sub>IN</sub> maximum cannot be respected, the injection current must be limited externally to the I<sub>INJ(PIN)</sub> value. A positive injection is induced by V<sub>IN</sub> < V<sub>SS</sub>. For true open-drain pads, there is no positive injection current, and the corresponding V<sub>IN</sub> maximum must always be respected.

3. All power ( $V_{DD}$ ) and ground ( $V_{SS}$ ) lines must always be connected to the external supply.

4. Negative injection disturbs the analog performance of the device. See note in "10-BIT ADC CHARACTERISTICS" on page 204.

5. When several inputs are submitted to a current injection, the maximum  $\Sigma I_{INJ(PIN)}$  is the absolute sum of the positive and negative injected currents (instantaneous values). These results are based on characterization with  $\Sigma I_{INJ(PIN)}$  maximum current injection on four I/O port pins of the device.

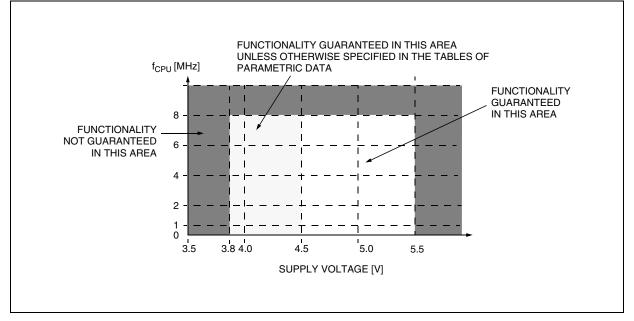

## **12.3 OPERATING CONDITIONS**

## **12.3.1 General Operating Conditions**

Symbol	Parameter	Conditions	Min	Max	Unit
f <sub>CPU</sub>	Internal clock frequency		0	8	MHz
	Extended Operating voltage	No Flash Write/Erase. Analog parameters not guaranteed.	3.8	4.5	V
$V_{DD}$	Standard Operating Voltage		4.5	5.5	
Op	Operating Voltage for Flash Write/Erase	V <sub>PP</sub> = 11.4 to 12.6V	4.5	5.5	
		1 Suffix Version	0	70	
		5 Suffix Version	-10	85	
T <sub>A</sub> An	Ambient temperature range	6 Suffix Version		85	°C
		7 Suffix Version	-40	105	
		3 Suffix Version		125	

## Figure 97. f<sub>CPU</sub> Maximum vs V<sub>DD</sub>

<u>(</u>ح)

## 12.3.2 Operating Conditions with Low Voltage Detector (LVD)

Subject to general operating conditions for T<sub>A</sub>.

Symbol	Parameter	Conditions	Min	Тур	Max	Unit
V <sub>IT+(LVD)</sub>	Reset release threshold (V <sub>DD</sub> rise)		4.0 <sup>1)</sup>	4.2	4.5	V
V <sub>IT-(LVD)</sub>	Reset generation threshold (V <sub>DD</sub> fall)		3.8	4.0	4.25 <sup>1)</sup>	v
V <sub>hys(LVD)</sub>	LVD voltage threshold hysteresis <sup>1)</sup>	V <sub>IT+(LVD)</sub> -V <sub>IT-(LVD)</sub>	150	200	250	mV
1/+	V <sub>DD</sub> rise time rate <sup>1)</sup>		6			μs/V
Vt <sub>POR</sub>					100	ms/V
t <sub>g(VDD)</sub>	$V_{DD}$ glitches filtered (not detected) by $LVD^{1)}$	Measured at V <sub>IT-(LVD)</sub>			40	ns

Notes:

1. Data based on characterization results, not tested in production.

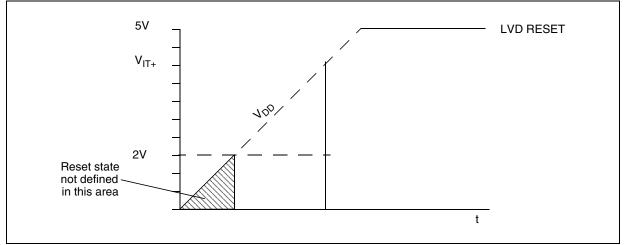

## 12.3.3 Auxiliary Voltage Detector (AVD) Thresholds

Subject to general operating conditions for T<sub>A</sub>.

Symbol	Parameter	Conditions	Min	Тур	Max	Unit
V <sub>IT+(AVD)</sub>	1⇒0 AVDF flag toggle threshold (V <sub>DD</sub> rise)		4.4 <sup>1)</sup>	4.6	4.9	V
V <sub>IT-(AVD)</sub>	$0 \Rightarrow 1 \text{ AVDF flag toggle threshold}$ (V <sub>DD</sub> fall)		4.2	4.4	4.65 <sup>1)</sup>	v
V <sub>hys(AVD)</sub>	AVD voltage threshold hysteresis	V <sub>IT+(AVD)</sub> -V <sub>IT-(AVD)</sub>		250		
$\Delta V_{IT-}$	Voltage drop between AVD flag set and LVD reset activated	V <sub>IT-(AVD)</sub> -V <sub>IT-(LVD)</sub>		450		mV

1. Data based on characterization results, not tested in production.

## Figure 98. LVD Startup Behavior

**Note:** When the LVD is enabled, the MCU reaches its authorized operating voltage from a reset state. However, in some devices, the reset signal may be undefined until  $V_{DD}$  is approximately 2V. As a consequence, the I/Os may toggle when  $V_{DD}$  is below this voltage.

Because Flash write access is impossible below this voltage, the Flash memory contents will not be corrupted.

## **12.4 SUPPLY CURRENT CHARACTERISTICS**

The following current consumption specified for the ST7 functional operating modes over temperature range does not take into account the clock source current consumption. To get the total device consumption, the two current values must be added (except for HALT mode for which the clock is stopped).

Symbol	Parameter	Conditions	Flash [	Devices	ROM	Devices	Unit
Symbol	Farameter	Conditions	Typ <sup>1)</sup>	Max <sup>2)</sup>	Typ <sup>1</sup>	Max <sup>2)</sup>	Unit
	Supply current in RUN mode <sup>3)</sup>	$ \begin{array}{l} f_{OSC} = 2 \mbox{ MHz},  f_{CPU} = 1 \mbox{ MHz} \\ f_{OSC} = 4 \mbox{ MHz},  f_{CPU} = 2 \mbox{ MHz} \\ f_{OSC} = 8 \mbox{ MHz},  f_{CPU} = 4 \mbox{ MHz} \\ f_{OSC} = 16 \mbox{ MHz},  f_{CPU} = 8 \mbox{ MHz} \end{array} $	1.8 3.2 6 10	3 5 8 15	1.1 2.2 4.4 8.9	2 3.5 6 12	
	Supply current in SLOW mode <sup>3)</sup>	$ \begin{array}{l} f_{OSC} = 2 \mbox{ MHz}, f_{CPU} = 62.5 \mbox{kHz} \\ f_{OSC} = 4 \mbox{ MHz}, f_{CPU} = 125 \mbox{ kHz} \\ f_{OSC} = 8 \mbox{ MHz}, f_{CPU} = 250 \mbox{ kHz} \\ f_{OSC} = 16 \mbox{ MHz}, f_{CPU} = 500 \mbox{ kHz} \end{array} $	0.5 0.6 0.85 1.25	2.7 3 3.6 4	0.1 0.2 0.4 0.8	0.2 0.4 0.8 1.5	mA
I <sub>DD</sub>	Supply current in WAIT mode <sup>3)</sup>	$ \begin{array}{l} f_{OSC} = 2 \ \text{MHz}, \ f_{CPU} = 1 \ \text{MHz} \\ f_{OSC} = 4 \ \text{MHz}, \ f_{CPU} = 2 \ \text{MHz} \\ f_{OSC} = 8 \ \text{MHz}, \ f_{CPU} = 4 \ \text{MHz} \\ f_{OSC} = 16 \ \text{MHz}, \ f_{CPU} = 8 \ \text{MHz} \end{array} $	1 1.8 3.4 6.4	3 4 5 7	0.7 1.4 2.9 5.7	3 4 5 7	ША
	Supply current in SLOW WAIT mode <sup>2)</sup>	$\begin{array}{l} f_{OSC} = 2 \mbox{ MHz},  f_{CPU} = 62.5 \mbox{ kHz} \\ f_{OSC} = 4 \mbox{ MHz},  f_{CPU} = 125 \mbox{ kHz} \\ f_{OSC} = 8 \mbox{ MHz},  f_{CPU} = 250 \mbox{ kHz} \\ f_{OSC} = 16 \mbox{ MHz},  f_{CPU} = 500 \mbox{ kHz} \end{array}$	0.4 0.5 0.6 0.8	1.2 1.3 1.8 2	0.07 0.14 0.28 0.56	0.12 0.25 0.5 1	
	Supply current in HALT mode <sup>4)</sup>	$V_{DD} = 5.5V \frac{-40^{\circ}C \le T_A \le +85^{\circ}C}{-40^{\circ}C \le T_A \le +125^{\circ}C}$	<1	10 50	<1	10 50	μA
	Supply current in ACTIVE HALT mode <sup>4)5)</sup>	· · · · · · · · · · · · · · · · · · ·	0.5	1.2	0.18	0.25	mA
	Supply current in AWUFH mode <sup>4)5)</sup>	$V_{DD} = 5.5V \frac{-40^{\circ}C \le T_A \le +85^{\circ}C}{-40^{\circ}C \le T_A \le +125^{\circ}C}$	25	30 70	25	30 70	μA

#### Notes:

1. Typical data are based on  $T_A = 25^{\circ}C$ ,  $V_{DD} = 5V$  (4.5V  $\leq V_{DD} \leq 5.5V$  range).

2. Data based on characterization results, tested in production at  $V_{DD}$  max.,  $f_{CPU}$  max. and  $T_A$  max.

3. Measurements are done in the following conditions:

- Program executed from Flash, CPU running with Flash (for flash devices).
- All I/O pins in input mode with a static value at  $V_{\text{DD}}$  or  $V_{\text{SS}}$  (no load)
- All peripherals in reset state.
- Clock input (OSC1) driven by external square wave.
- In SLOW and SLOW WAIT mode, f<sub>CPU</sub> is based on f<sub>OSC</sub> divided by 32.

To obtain the total current consumption of the device, add the clock source (Section 12.5.3) and the peripheral power consumption (Section 12.4.2).

4. All I/O pins in input mode with a static value at V<sub>DD</sub> or V<sub>SS</sub> (no load). Data based on characterization results, tested in production at V<sub>DD</sub> max.,  $f_{CPU}$  max. and  $T_A$  max.

5. This consumption refers to the Halt period only and not the associated run period which is software dependent.

## SUPPLY CURRENT CHARACTERISTICS (Cont'd)

## 12.4.1 Supply and Clock Managers

The previous current consumption specified for the ST7 functional operating modes over temperature range does not take into account the clock source current consumption. To obtain the total device consumption, the two current values must be added (except for HALT mode).

Symbol	Parameter	Conditions	Тур	Max <sup>1)</sup>	Unit
I <sub>DD(RES)</sub>	Supply current of resonator oscillator <sup>2)3)</sup>		See Section 12.5.3 on page 187		
I <sub>DD(PLL)</sub>	PLL supply current	$V_{DD} = 5V$	360		μA
I <sub>DD(LVD)</sub>	LVD supply current	HALT mode, $V_{DD} = 5V$	150	300	

Notes:

1. Data based on characterization results, not tested in production.

2. Data based on characterization results done with the external components specified in Section 12.5.3, not tested in production.

3. As the oscillator is based on a current source, the consumption does not depend on the voltage.

## 12.4.2 On-Chip Peripherals

#### $T_A = 25^{\circ}C$ , $f_{CPU} = 8$ MHz.

Symbol	Parameter	Conditions		Тур	Unit

## Figure 99. Typical Application with an External Clock Source

#### Notes:

1. Data based on typical application software.

2. Time measured between interrupt event and interrupt vector fetch.  $\Delta t_{c(INST)}$  is the number of  $t_{CPU}$  cycles needed to finish the current instruction execution.

3. Data based on design simulation and/or technology characteristics, not tested in production.

## CLOCK AND TIMING CHARACTERISTICS (Cont'd)

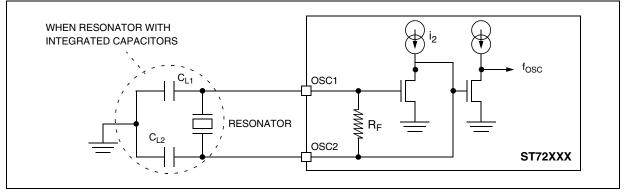

## 12.5.3 Crystal and Ceramic Resonator Oscillators

The ST7 internal clock can be supplied with four different Crystal/Ceramic resonator oscillators. All the information given in this paragraph is based on characterization results with specified typical external components. In the application, the resonator and the load capacitors have to be placed as close as possible to the oscillator pins in order to minimize output distortion and start-up stabilization time. Refer to the crystal/ceramic resonator manufacturer for more details (frequency, package, accuracy...).  $^{1/2}$

#### Figure 100. Typical Application with a Crystal or Ceramic Resonator

#### Notes:

5/

1. Resonator characteristics given by the crystal/ceramic resonator manufacturer.

2.  $t_{SU(OSC)}$  is the typical oscillator start-up time measured between  $V_{DD}$  = 2.8V and the fetch of the first instruction (with a quick  $V_{DD}$  ramp-up from 0 to 5V (< 50µs).

3. The oscillator selection can be optimized in terms of supply current using an high quality resonator with small R<sub>S</sub> value. Refer to crystal/ceramic resonator manufacturer for more details.

## CLOCK CHARACTERISTICS (Cont'd)

## **12.5.4 PLL Characteristics**

Operating conditions: V<sub>DD</sub> 3.8 to 5.5V @ T<sub>A</sub> 0 to 70°C<sup>1)</sup> or V<sub>DD</sub> 4.5 to 5.5V @ T<sub>A</sub> -40 to 125°C

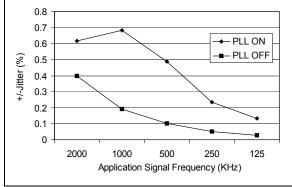

Symbol	Parameter	Conditions	Min	Тур	Max	Unit
V	PLL Voltage Bange	$T_A = 0$ to $+70^{\circ}C$	3.8		5.5	
V <sub>DD(PLL)</sub>		$T_{A} = -40 \text{ to } +125^{\circ}\text{C}$	4.5		5.5	
f <sub>OSC</sub>	PLL input frequency range		2		4	MHz
A fam./fam.	PLL jitter <sup>1)</sup>	$f_{OSC}$ = 4 MHz, $V_{DD}$ = 4.5 to 5.5V		Note 2		%
$\Delta f_{CPU}/f_{CPU}$		$f_{OSC} = 2 \text{ MHz}, V_{DD} = 4.5 \text{ to } 5.5 \text{V}$				/0

#### Notes:

1. Data characterized but not tested.

2. Under characterization

### Figure 101. PLL Jitter vs Signal Frequency<sup>1)</sup>

#### Notes:

1. Measurement conditions:  $f_{CPU} = 4 \text{ MHz}$ ,  $T_A = 25^{\circ}C$ 

The user must take the PLL jitter into account in the application (for example in serial communication or sampling of high frequency signals). The PLL jitter is a periodic effect, which is integrated over several CPU cycles. Therefore, the longer the period of the application signal, the less it is impacted by the PLL jitter.

Figure 101 shows the PLL jitter integrated on application signals in the range 125 kHz to 2 MHz. At frequencies of less than 125 kHz, the jitter is negligible.

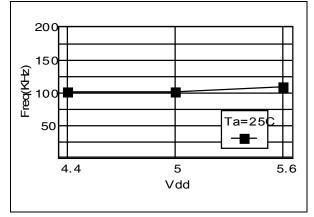

## CLOCK CHARACTERISTICS (Cont'd)

## 12.6 Auto Wakeup from Halt Oscillator (AWU)

Symbol	Parameter	Conditions	Min	Тур	Max	Unit
f <sub>AWU</sub>	AWU oscillator frequency <sup>1)</sup>		50	100	250	kHz
t <sub>RCSRT</sub>	AWU oscillator startup time			10		μs

1. Data based on characterization results, not tested in production.

t <sub>RET</sub>	Data retention	T <sub>A</sub> = 105°C	25			years
		T <sub>A</sub> = 125°C	10			
N <sub>RW</sub>	Write erase cycles	T <sub>A</sub> = 25°C	100			cycles
T <sub>PROG</sub> T <sub>ERASE</sub>	Programming or erasing temperature range		-40	25	85	°C

#### Notes:

1. Minimum  $V_{DD}$  supply voltage without losing data stored in RAM (in HALT mode or under RESET) or in hardware registers (only in HALT mode). Not tested in production.

47/

2. Data based on characterization results, not tested in production.

3. V<sub>PP</sub> must be applied only during the programming or erasing operation and not permanently for reliability reasons.

4. Data based on simulation results, not tested in production.

5. In Write / erase mode the  $I_{DD}$  supply current consumption is the same as in Run mode (see Section 12.2.2)

## **12.8 EMC CHARACTERISTICS**

Susceptibility tests are performed on a sample basis during product characterization.

# 12.8.1 Functional EMS (Electro Magnetic Susceptibility)

Based on a simple running application on the product (toggling two LEDs through I/O ports), the product is stressed by two electro magnetic events until a failure occurs (indicated by the LEDs).

- ESD: Electro-Static Discharge (positive and negative) is applied on all pins of the device until a functional disturbance occurs. This test conforms with the IEC 1000-4-2 standard.
- FTB: A Burst of Fast Transient voltage (positive and negative) is applied to V<sub>DD</sub> and V<sub>SS</sub> through a 100pF capacitor, until a functional disturbance occurs. This test conforms with the IEC 1000-4-4 standard.

A device reset allows normal operations to be resumed. The test results are given in the table below based on the EMS levels and classes defined in application note AN1709.

# 12.8.1.1 Designing hardened software to avoid noise problems

EMC characterization and optimization are performed at component level with a typical application environment and simplified MCU software. It should be noted that good EMC performance is highly dependent on the user application and the software in particular.

Therefore it is recommended that the user applies EMC software optimization and prequalification tests in relation with the EMC level requested for his application.

#### Software recommendations:

The software flowchart must include the management of runaway conditions such as:

- Corrupted program counter
- Unexpected reset
- Critical Data corruption (control registers...)

#### **Prequalification trials:**

Most of the common failures (unexpected reset and program counter corruption) can be reproduced by manually forcing a low state on the RE-SET pin or the Oscillator pins for 1 second.

To complete these trials, ESD stress can be applied directly on the device, over the range of specification values. When unexpected behavior is detected, the software can be hardened to prevent unrecoverable errors occurring (see application note AN1015).

Symbol	Parameter	Conditions	Level/ Class
V <sub>FESD</sub>	Voltage limits to be applied on any I/O pin to induce a functional disturbance	$V_{DD} = 5V$ , $T_A = +25^{\circ}C$ , $f_{OSC} = 8$ MHz conforms to IEC 1000-4-2	
V <sub>FFTB</sub>	Fast transient voltage burst limits to be applied through 100pF on $V_{DD}$ and $V_{DD}$ pins to induce a functional disturbance	$V_{DD} = 5V$ , $T_A = +25^{\circ}C$ , $f_{OSC} = 8$ MHz conforms to IEC 1000-4-4	3B

#### 12.8.2 Electro Magnetic Interference (EMI)

Based on a simple application running on the product (toggling two LEDs through the I/O ports), the product is monitored in terms of emission. This

emission test is in line with the norm SAE J 1752/ 3 which specifies the board and the loading of each pin.

Symbol	Parameter	Conditions	Monitored	Max vs. [	fosc/fcpu]	Unit
Cymbol	Farameter	Conditions	Frequency Band	8/4 MHz	16/8 MHz	
			0.1 MHz to 30 MHz	31	32	
		Flash devices: $V_{DD} = 5V$ , $T_A = +25^{\circ}C$ , LQFP64 package	30 MHz to 130 MHz	32	37	dBµV
		conforming to SAE J 1752/3	130 MHz to 1 GHz	11	16	
S	Peak level	<b>3 1 1 1</b>	SAE EMI Level	3.0	3.5	-
S <sub>EMI</sub>	i eak level		0.1 MHz to 30 MHz	10	18	
		ROM devices: $V_{DD} = 5V$ , $T_A = +25^{\circ}C$ , LQFP64 package	30 MHz to 130 MHz	15	25	dBµV
		conforming to SAE J 1752/3	130 MHz to 1 GHz	-3	1	
		<b>G</b>	SAE EMI Level	2.0	2.5	-

Notes:

1. Not tested in production.

### EMC CHARACTERISTICS (Cont'd)

# 12.8.3 Absolute Maximum Ratings (Electrical Sensitivity)

Based on three different tests (ESD, LU and DLU) using specific measurement methods, the product is stressed in order to determine its performance in terms of electrical sensitivity (see Table 32 and Table 33 below). For more details, refer to application note AN1181.

#### 12.8.3.1 Electro-Static Discharge (ESD)

Electro-Static Discharges (a positive then a negative pulse separated by 1 second) are applied to the pins of each sample according to each pin combination. The sample size depends on the number of supply pins in the device (3 parts\*(n+1) supply pin). Two models can be simulated: Human Body Model and Machine Model. This test conforms to the JESD22-A114A/A115A standard.

#### 12.8.3.2 Static and Dynamic Latch-Up

- LU: Three complementary static tests are required on 10 parts to assess the latch-up performance. A supply overvoltage (applied to each power supply pin) and a current injection (applied to each input, output and configurable I/ O pin) are performed on each sample. This test conforms to the EIA/JESD 78 IC latch-up standard. For more details, refer to application note AN1181.
- DLU: Electro-Static Discharges (one positive then one negative test) are applied to each pin of three samples when the micro is running to assess the latch-up performance in dynamic mode. Power supplies are set to the typical values, the oscillator is connected as near as possible to the pins of the micro and the component is put in reset mode. This test conforms to the IEC1000-4-2 and SAEJ1752/3 standards. For more details, refer to application note AN1181.

#### Table 32. Absolute Maximum Ratings

Symbol	Ratings	Conditions	Maximum value <sup>1)</sup>	Unit
V <sub>ESD(HBM)</sub>	Electro-static discharge voltage (Human Body Model)		2000	
V <sub>ESD(MM)</sub>	Electro-static discharge voltage (Machine Model)	T <sub>∆</sub> = +25°C	200	v
V <sub>ESD(CDM)</sub>	Electro-static discharge voltage (Charge Device Model)	14 1200	750 on corner pins, 500 on others	

Notes:

1. Data based on characterization results, not tested in production.

#### **Table 33. Electrical Sensitivities**

Symbol	Parameter	Conditions	Class <sup>1)</sup>
LU	Static latch-up class	$T_A = +25^{\circ}C$ $T_A = +85^{\circ}C$ $T_A = +125^{\circ}C$	A
DLU	Dynamic latch-up class	$V_{DD} = 5.5V, f_{OSC} = 4 \text{ MHz}, T_A = +25^{\circ}\text{C}$	

Notes:

1. Class description: A Class is an STMicroelectronics internal specification. All its limits are higher than the JEDEC specifications, that means when a device belongs to Class A it exceeds the JEDEC standard. B Class strictly covers all the JEDEC criteria (international standard).

## **12.9 I/O PORT PIN CHARACTERISTICS**

## 12.9.1 General Characteristics

Subject to general operating conditions for  $V_{DD}$ ,  $f_{OSC}$ , and  $T_A$  unless otherwise specified.

Symbol	Parameter	Cor	nditions	Min	Тур	Max	Unit
V <sub>IL</sub>	Input low level voltage <sup>1)</sup>					$0.3 \times V_{DD}$	
V <sub>IH</sub>	Input high level voltage <sup>1)</sup>	CMOS ports		$0.7  ext{ x V}_{ ext{DD}}$			
V <sub>hys</sub>	Schmitt trigger voltage hysteresis <sup>2)</sup>				1		V
V <sub>IL</sub>	Input low level voltage <sup>1)</sup>					0.8	
V <sub>IH</sub>	Input high level voltage <sup>1)</sup>	TTL ports		2			
V <sub>hys</sub>	Schmitt trigger voltage hysteresis <sup>2)</sup>				400		mV
	Injected Current on PB3		Flash devices	0		+4	
I <sub>INJ(PIN)</sub>	injected Current on FBS	_	ROM devices			±4	
	Injected Current on any other I/O pin					±4	mA
ΣΙ <sub>INJ(PIN)</sub> <sup>3)</sup>	Total injected current (sum of all I/O and control pins) <sup>7)</sup>					±25	
	Input leakage current on robust pins	See "10-B	IT ADC CHARA	CTERISTIC	S" on pag	e 204	
l <sub>lkg</sub>	Input leakage current <sup>4)</sup>	$V_{SS} \le V_{IN}$	$\leq V_{DD}$			±1	
ا <sub>S</sub>	Static current consumption <sup>5)</sup>	Floating in	put mode		200		μA
R <sub>PU</sub>	Weak pull-up equivalent resistor <sup>6)</sup>	$V_{IN} = V_{SS}$	$V_{DD} = 5V$	50	90	250	kΩ
C <sub>IO</sub>	I/O pin capacitance		•		5		pF
t <sub>f(IO)out</sub>	Output high to low level fall time	C <sub>L</sub> = 50pF			25		20
t <sub>r(IO)out</sub>	Output low to high level rise time	Between 10% and 90%			20		ns
t <sub>w(IT)in</sub>	External interrupt pulse time <sup>7)</sup>			1			t <sub>CPU</sub>

#### Notes:

1. Data based on characterization results, not tested in production.

2. Hysteresis voltage between Schmitt trigger switching levels. Based on characterization results, not tested.

3. When the current limitation is not possible, the V<sub>IN</sub> absolute maximum rating must be respected, otherwise refer to  $I_{INJ(PIN)}$  specification. A positive injection is induced by  $V_{IN} > V_{DD}$  while a negative injection is induced by  $V_{IN} < V_{SS}$ . Refer to Section 12.2 on page 180 for more details.

4. Leakage could be higher than max. if negative current is injected on adjacent pins.

5. Configuration not recommended, all unused pins must be kept at a fixed voltage: Using the output mode of the I/O, for example, or an external pull-up or pull-down resistor (see Figure 103). Data based on design simulation and/or technology characteristics, not tested in production.

6. The  $R_{PU}$  pull-up equivalent resistor is based on a resistive transistor (corresponding  $I_{PU}$  current characteristics described in Figure 104).

7. To generate an external interrupt, a minimum pulse width must be applied on an I/O port pin configured as an external interrupt source.

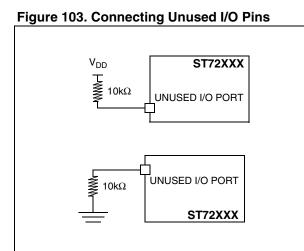

Figure 104.  $R_{PU}$  vs  $V_{DD}$  with  $V_{IN} = V_{SS}$ 

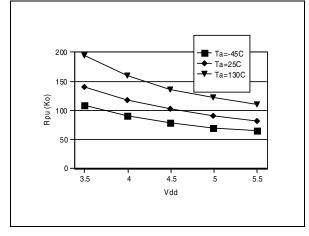

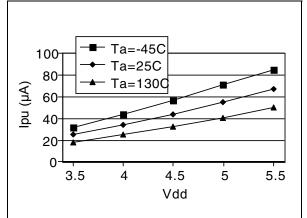

Figure 105.  $I_{PU}$  vs  $V_{DD}$  with  $V_{IN} = V_{SS}$ 

## 12.9.2 Output Driving Current

Subject to general operating conditions for V<sub>DD</sub>, f<sub>OSC</sub>, and T<sub>A</sub> unless otherwise specified.

Symbol	Parameter		Conditions	Min	Max	Unit
	Output low level voltage for a standard I/O pin		I <sub>IO</sub> =+5mA		1.2	
1)	when eight pins are sunk at same time (see Figure 106)		I <sub>IO</sub> =+2mA		0.5	
V <sub>OL</sub> <sup>1)</sup>	Output low level voltage for a high sink I/O pin when four pins are sunk at same time	)=5V	$I_{IO}$ =+20mA, $T_A \leq 85^{\circ}C$ $T_A \geq 85^{\circ}C$		1.3 1.5	v
	(see Figure 107 and Figure 110)	V <sub>DD</sub>	I <sub>IO</sub> =+8mA		0.6	
V <sub>OH</sub> <sup>2)</sup>	Output high level voltage for an I/O pin when four pins are sourced at same time		$I_{IO}$ =-5mA, $T_A \leq 85^{\circ}C$ $T_A \geq 85^{\circ}C$			
	(see Figure 108 and Figure 111)		I <sub>IO</sub> =-2mA	V <sub>DD</sub> -0.7		

## Figure 106. Typical V<sub>OL</sub> at V<sub>DD</sub> = 5V (Standard)

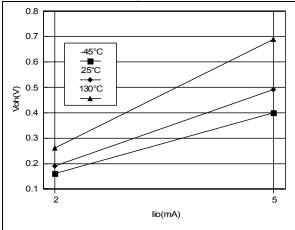

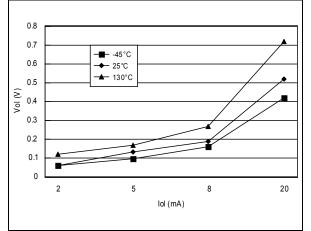

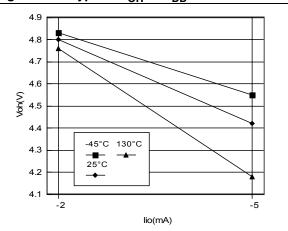

Figure 107. Typical V<sub>OL</sub> at V<sub>DD</sub> = 5V (High-sink)

## Figure 108. Typical $V_{OH}$ at $V_{DD}$ = 5V

#### Notes:

<u>ل</u>حک

1. The  $I_{IO}$  current sunk must always respect the absolute maximum rating specified in Section 12.2.2 and the sum of  $I_{IO}$  (I/O ports and control pins) must not exceed  $I_{VSS}$ .

2. The I<sub>IO</sub> current sourced must always respect the absolute maximum rating specified in Section 12.2.2 and the sum of I<sub>IO</sub> (I/O ports and control pins) must not exceed I<sub>VDD</sub>. True open drain I/O pins does not have V<sub>OH</sub>.

## Figure 109. Typical V<sub>OL</sub> vs V<sub>DD</sub> (Standard I/Os)

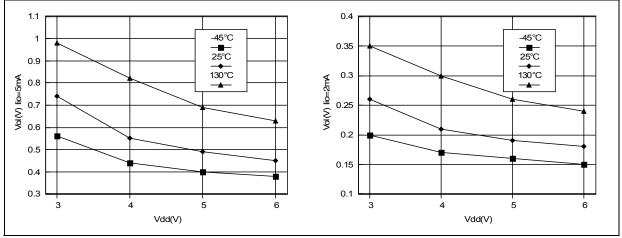

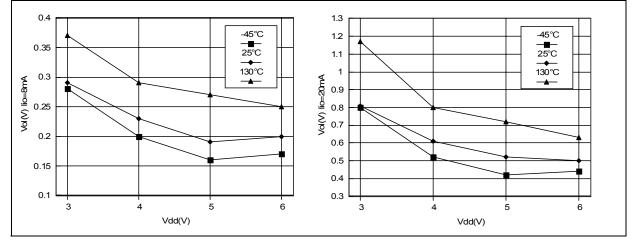

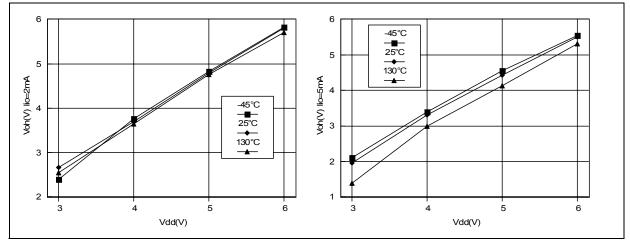

Figure 110. Typical V<sub>OL</sub> vs V<sub>DD</sub> (High-sink I/Os)

57

## **12.10 CONTROL PIN CHARACTERISTICS**

## 12.10.1 Asynchronous RESET Pin

Subject to general operating conditions for  $V_{DD}$ ,  $f_{OSC}$ , and  $T_A$  unless otherwise specified.

Symbol	Parameter	Conditions		Min	Тур	Max	Unit		
V <sub>IL</sub>	Input low level voltage <sup>1)</sup>					0.3 x V <sub>DD</sub>			
V <sub>IH</sub>	Input high level voltage <sup>1)</sup>			$0.7 \times V_{DD}$					
V <sub>hys</sub>	Schmitt trigger voltage hysteresis <sup>2)</sup>	$V_{DD} = 5V$			1.5		V		
V <sub>OL</sub>	Output low level voltage <sup>3)</sup>	$V_{DD} = 5V$	I <sub>IO</sub> = +5mA		0.68	0.95			
VOL VOL	Output low level voltage	$v_{DD} = 5v$	$v_{DD} = 5v$	$v_{DD} = 5v$	$I_{IO} = +2mA$		0.28	0.45	
R <sub>ON</sub>	Weak pull-up equivalent resistor <sup>4)</sup>	$V_{IN} = V_{SS}$		20	40	80	kΩ		
t <sub>w(RSTL)out</sub>	Generated reset pulse duration	Internal res	set source		30				
t <sub>h(RSTL)in</sub>	External reset pulse hold time <sup>5)</sup>			2.5			μs		
t <sub>g(RSTL)in</sub>	Filtered glitch duration <sup>6)</sup>				200		ns		

#### Notes:

1. Data based on characterization results, not tested in production.

2. Hysteresis voltage between Schmitt trigger switching levels.

3. The I<sub>IO</sub> current sunk must always respect the absolute maximum rating specified in Section 12.2.2 and the sum of I<sub>IO</sub> (I/O ports and control pins) must not exceed I<sub>VSS</sub>.

4. To guarantee the reset of the device, a minimum pulse has to be applied to the  $\overline{\text{RESET}}$  pin. All short pulses applied on the RESET pin with a duration below  $t_{h(\text{RSTL})in}$  can be ignored.

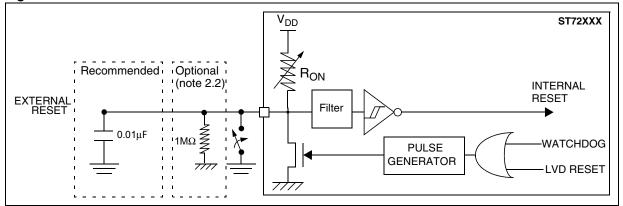

5. The reset network (the resistor and two capacitors) protects the device against parasitic resets, especially in noisy environments.

6. Data guaranteed by design, not tested in production.

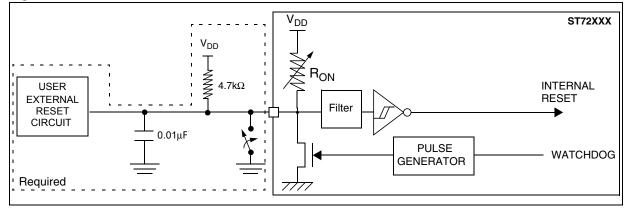

## CONTROL PIN CHARACTERISTICS (Cont'd)

## Figure 112. RESET Pin Protection When LVD Is Enabled<sup>1)2)</sup>

## Figure 113. RESET Pin Protection When LVD Is Disabled<sup>1)</sup>

#### Note 1:

1.1 The reset network protects the device against parasitic resets.

1.2 The output of the external reset circuit must have an open-drain output to drive the ST7 reset pad. Otherwise the device can be damaged when the ST7 generates an internal reset (LVD or watchdog).

1.3 Whatever the reset source is (internal or external), the user must ensure that the level on the  $\overline{\text{RESET}}$  pin can go below the V<sub>IL</sub> max. level specified in Section 12.10.1. Otherwise the reset will not be taken into account internally.

1.4 Because the reset circuit is designed to allow the internal RESET to be output in the RESET pin, the user must ensure that the current sunk on the RESET pin (by an external pull-up for example) is less than the absolute maximum value specified for I<sub>INJ(RESET)</sub> in Section 12.2.2 on page 180.

#### Note 2:

57

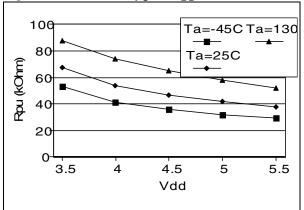

2.1 When the LVD is enabled, it is mandatory not to connect a pull-up resistor. A 10nF pull-down capacitor is recommended to filter noise on the reset line.

2.2. In case a capacitive power supply is used, it is recommended to connect a1MW pull-down resistor to the RESET pin to discharge any residual voltage induced by this capacitive power supply (this will add 5µA to the power consumption of the MCU).

2.3. Tips when using the LVD:

- 1. Check that all recommendations related to reset circuit have been applied (see notes above)
- 2. Check that the power supply is properly decoupled (100nF + 10μF close to the MCU). Refer to AN1709. If this cannot be done, it is recommended to put a 100nF + 1MW pull-down on the RESET pin.
- 3. The capacitors connected on the RESET pin and also the power supply are key to avoiding any start-up marginality. In most cases, steps 1 and 2 above are sufficient for a robust solution. Otherwise: Replace 10nF pull-down on the RESET pin with a 5µF to 20µF capacitor.

## CONTROL PIN CHARACTERISTICS (Cont'd)

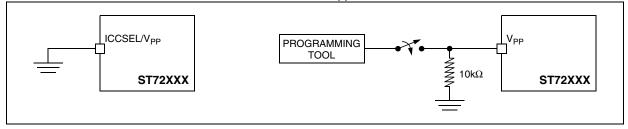

## Figure 114. RESET R<sub>PU</sub> vs V<sub>DD</sub>

## 12.10.2 ICCSEL/V<sub>PP</sub> Pin

Subject to general operating conditions for  $V_{DD}$ ,  $f_{OSC}$ , and  $T_A$  unless otherwise specified.

Symbol	Parameter	Conditions	Min	Max	Unit
V <sub>IL</sub>	Input low level voltage <sup>1)</sup>		V <sub>SS</sub>	0.2	V
V <sub>IH</sub>	Input high level voltage <sup>1)</sup>		V <sub>DD</sub> -0.1	12.6	v
١L	Input leakage current	$V_{IN} = V_{SS}$		±1	μA

## Figure 115. Two Typical Applications with ICCSEL/V<sub>PP</sub> Pin<sup>2)</sup>

#### Notes:

- 1. Data based on design simulation and/or technology characteristics, not tested in production.
- 2. When ICC mode is not required by the application ICCSEL/V<sub>PP</sub> pin must be tied to  $V_{SS}$ .

## **12.11 TIMER PERIPHERAL CHARACTERISTICS**

Subject to general operating conditions for  $V_{DD}, f_{OSC},$  and  $T_A$  unless otherwise specified.

Refer to I/O port characteristics for more details on the input/output alternate function characteristics (output compare, input capture, external clock, PWM output...).

### 12.11.1 8-Bit PWM-ART Autoreload Timer

Symbol	Parameter	Conditions	Min	Тур	Max	Unit

## Figure 116. SPI Slave Timing Diagram with CPHA = $0^{3}$

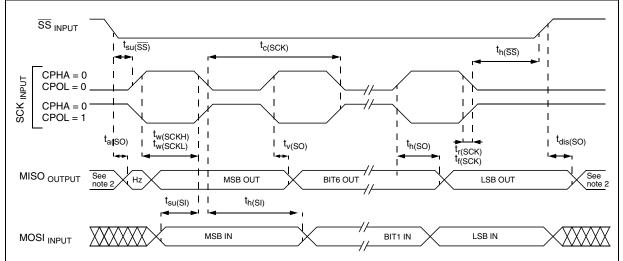

#### Notes:

- 1. Data based on design simulation and/or characterization results, not tested in production.
- 2. When no communication is on-going the data output line of the SPI (MOSI in master mode, MISO in slave mode) has its alternate function capability released. In this case, the pin status depends on the I/O port configuration.
- 3. Measurement points are done at CMOS levels: 0.3 x  $V_{\text{DD}}$  and 0.7 x  $V_{\text{DD}}.$
- 4. Depends on  $f_{CPU}$ . For example, if  $f_{CPU} = 8$  MHz, then  $T_{CPU} = 1 / f_{CPU} = 125$ ns and  $t_{su(\overline{SS})} = 550$ ns.

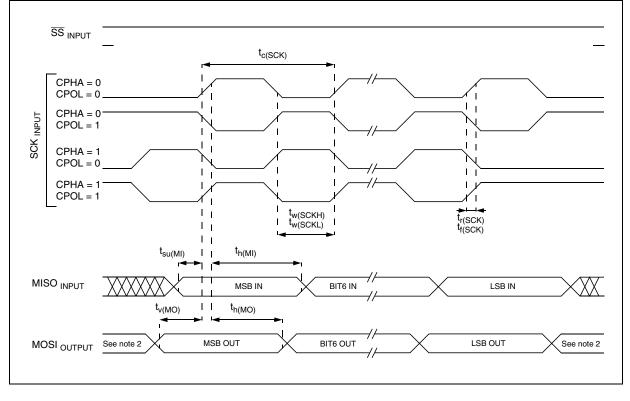

## COMMUNICATION INTERFACE CHARACTERISTICS (Cont'd)

## Figure 117. SPI Slave Timing Diagram with CPHA = 1<sup>1)</sup>

#### Notes:

- 1. Measurement points are done at CMOS levels: 0.3 x  $V_{\text{DD}}$  and 0.7 x  $V_{\text{DD}}.$
- 2. When no communication is on-going the data output line of the SPI (MOSI in master mode, MISO in slave mode) has its alternate function capability released. In this case, the pin status depends on the I/O port configuration.

## COMMUNICATIONS INTERFACE CHARACTERISTICS (Cont'd)

## **12.13 10-BIT ADC CHARACTERISTICS**

Subject to general operating conditions for  $V_{\text{DD}}, f_{\text{CPU}},$  and  $T_{\text{A}}$  unless otherwise specified.

Symbol	Parameter	Conditions	Min <sup>1)</sup>	Тур	Max <sup>1)</sup>	Unit
f <sub>ADC</sub>	ADC clock frequency		0.4		4	MHz
V <sub>AIN</sub>	Conversion voltage range <sup>2)</sup>		$V_{SSA}$		V <sub>DDA</sub>	V
R <sub>AIN</sub>	External input impedance				see Figure	kΩ
C <sub>AIN</sub>	External capacitor on analog input				119 and	pF
f <sub>AIN</sub>	Variation frequency of analog input signal				Figure 120	Hz
l <sub>lkg</sub>	Negative input leakage current on ro- bust analog pins (refer to Table 1 on page 9)	V <sub>IN</sub> < V <sub>SS,</sub>   I <sub>IN</sub>   < 400µA on adjacent robust analog pin		5	6	μA
C <sub>ADC</sub>	Internal sample and hold capacitor			6		pF
+	Conversion time	f <sub>ADC</sub> = 4 MHz		3.5		μs
t <sub>CONV</sub>	Conversion time			14		1/f <sub>ADC</sub>
	Analog part	Sunk on V <sub>DDA</sub> <sup>2)</sup>			3.6	mA
ADC	Digital part	Sunk on V <sub>DD</sub>			0.2	IIIA

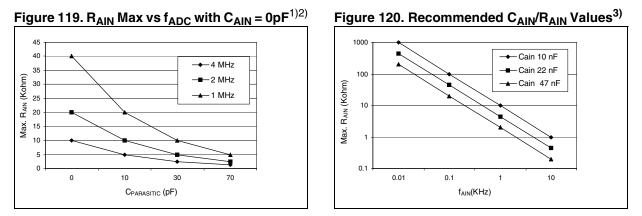

#### Notes:

1. Data based on characterization results, not tested in production.

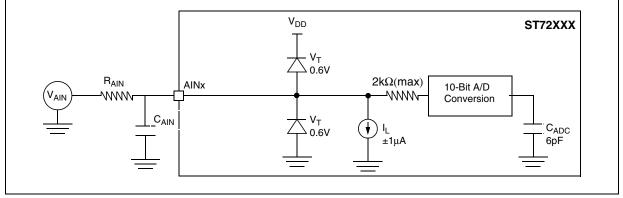

2. When  $V_{DDA}$  and  $V_{SSA}$  pins are not available on the pinout, the ADC refers to  $V_{DD}$  and  $V_{SS}$ .

## ADC CHARACTERISTICS (Cont'd)

### Figure 121. Typical Application with ADC

#### Notes:

Ĺ**Ţ**/

1.  $C_{PARASITIC}$  represents the capacitance of the PCB (dependent on soldering and PCB layout quality) plus the pad capacitance (3pF). A high  $C_{PARASITIC}$  value will downgrade conversion accuracy. To remedy this,  $f_{ADC}$  should be reduced. 2. Any added external serial resistor will downgrade the ADC accuracy (especially for resistance greater than 10k $\Omega$ ). Data based on characterization results, not tested in production.

3. This graph shows that depending on the input signal variation ( $f_{AIN}$ ),  $C_{AIN}$  can be increased for stabilization time and reduced to allow the use of a larger serial resistor ( $R_{AIN}$ ). It is valid for all  $f_{ADC}$  frequencies  $\leq 4$  MHz.

## ADC CHARACTERISTICS (Cont'd)

#### 12.13.0.1 Analog Power Supply and Reference Pins

Depending on the MCU pin count, the package may feature separate V<sub>DDA</sub> and V<sub>SSA</sub> analog power supply pins. These pins supply power to the A/D converter cell and function as the high and low reference voltages for the conversion. In smaller packages V<sub>DDA</sub> and V<sub>SSA</sub> pins are not available and the analog supply and reference pads are internally bonded to the V<sub>DD</sub> and V<sub>SS</sub> pins.

Separation of the digital and analog power pins allow board designers to improve A/D performance. Conversion accuracy can be impacted by voltage drops and noise in the event of heavily loaded or badly decoupled power supply lines (see Section 12.13.0.2 "General PCB Design Guidelines").

#### 12.13.0.2 General PCB Design Guidelines

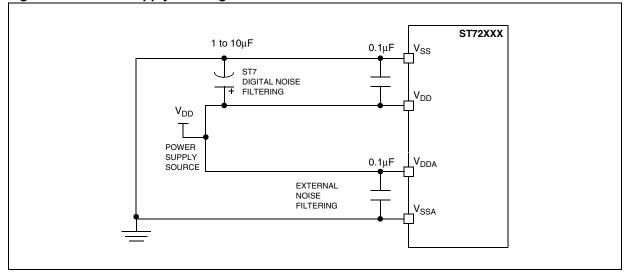

To obtain best results, some general design and layout rules should be followed when designing the application PCB to shield the noise-sensitive, analog physical interface from noise-generating CMOS logic signals.

 Use separate digital and analog planes. The analog ground plane should be connected to the digital ground plane via a single point on the PCB.

- Filter power to the analog power planes. It is recommended to connect capacitors, with good high frequency characteristics, between the power and ground lines, placing  $0.1\mu$ F and optionally, if needed 10pF capacitors as close as possible to the ST7 power supply pins and a 1 to  $10\mu$ F capacitor close to the power source (see Figure 122).
- The analog and digital power supplies should be connected in a star network. Do not use a resistor, as V<sub>DDA</sub> is used as a reference voltage by the A/D converter and any resistance would cause a voltage drop and a loss of accuracy.
- Properly place components and route the signal traces on the PCB to shield the analog inputs. Analog signals paths should run over the analog ground plane and be as short as possible. Isolate analog signals from digital signals that may switch while the analog inputs are being sampled by the A/D converter. Do not toggle digital outputs on the same I/O port as the A/D input being converted.

# 12.13.0.3 Software Filtering of Spurious Conversion Results

For EMC performance reasons, it is recommended to filter A/D conversion outliers using software filtering techniques.

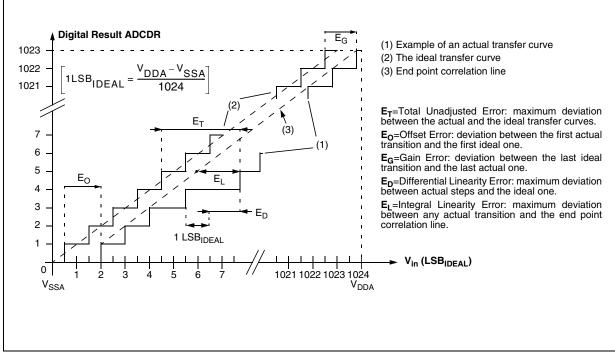

## Figure 122. Power Supply Filtering

## ADC CHARACTERISTICS (Cont'd)

Symbol	Parameter	Conditions	Тур	Max	Unit
IE <sub>T</sub> I	Total unadjusted error <sup>1)</sup>		4	Note 2	
IE <sub>O</sub> I	Offset error <sup>1)</sup>		2.5	4	
IE <sub>G</sub> I	Gain Error <sup>1)</sup>		3	4	LSB
IE <sub>D</sub> I	Differential linearity error <sup>1)</sup>		1.5	2	
IE <sub>L</sub> I	Integral linearity error <sup>1)</sup>		1.5	2	

### ADC Accuracy with $f_{CPU} = 8$ MHz, $f_{ADC} = 4$ MHz $R_{AIN} < 10 k_{\Omega}$ , $V_{DD} = 5V$

## Figure 123. ADC Accuracy Characteristics

#### Notes:

57/

1. Data based on characterization results, not tested in production. ADC Accuracy vs. Negative Injection Current: Injecting negative current on any of the standard (non-robust) analog input pins should be avoided as this significantly reduces the accuracy of the conversion being performed on another analog input. It is recommended to add a Schottky diode (pin to ground) to standard analog pins which may potentially inject negative current. The effect of negative injection current on robust pins is specified in Section 12.9.

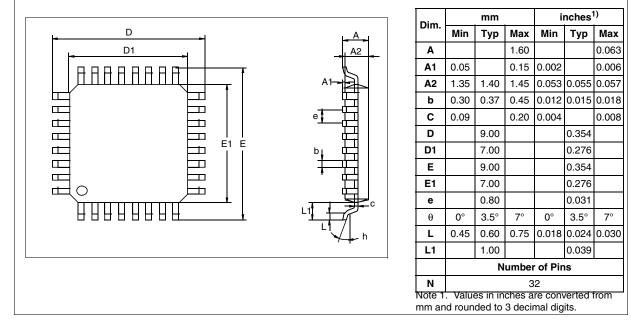

Any positive injection current within the limits specified for  $I_{INJ(PIN)}$  and  $\Sigma I_{INJ(PIN)}$  in Section 12.9 does not affect the ADC accuracy.

2. Under characterization.

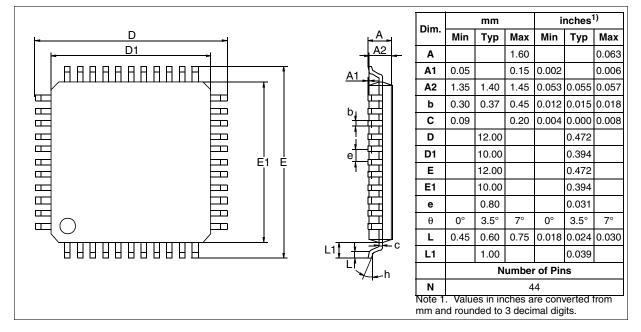

## **13 PACKAGE CHARACTERISTICS**

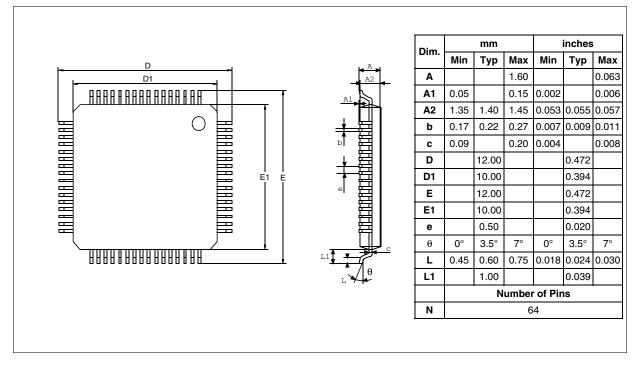

## **13.1 PACKAGE MECHANICAL DATA**

## Figure 124. 32-Pin Low Profile Quad Flat Package (7x7)

## Figure 126. 64-Pin Low Profile Quad Flat Package (10 x10)

## **13.2 THERMAL CHARACTERISTICS**

Symbol	Ratings	Value	Unit
R <sub>thJA</sub>	Package thermal resistance (junction to ambient) LQFP64 LQFP44 LQFP32	60 52 70	°C/W
PD	Power dissipation <sup>1)</sup>	500	mW
T <sub>Jmax</sub>	Maximum junction temperature <sup>2)</sup>	150	°C

#### Notes:

1. The maximum power dissipation is obtained from the formula  $P_D = (T_J - T_A) / R_{thJA}$ . The power dissipation of an application can be defined by the user with the formula:  $P_D = P_{INT} + P_{PORT}$  where  $P_{INT}$  is the chip internal power ( $I_{DD} \times V_{DD}$ ) and  $P_{PORT}$  is the port power dissipation depending on the ports used in the application.

2. The maximum chip-junction temperature is based on technology characteristics.

## **13.3 SOLDERING AND GLUEABILITY INFORMATION**

In order to meet environmental requirements, ST offers these devices in ECOPACK<sup>TM</sup> packages. These packages have a lead-free second level interconnect. The category of second level interconnect is marked on the package and on the inner

box label, in compliance with JEDEC Standard JESD97. The maximum ratings related to soldering conditions are also marked on the inner box label. ECOPACK is an ST trademark. ECOPACK<sup>TM</sup> specifications are available at www.st.com.

57

## **14 DEVICE CONFIGURATION AND ORDERING INFORMATION**

Each device is available for production in user programmable versions (FLASH) as well as in factory coded versions (ROM/FASTROM).

ST72361 devices are ROM versions. ST72P361 devices are Factory Advanced Service Technique ROM (FASTROM) versions: They are factory-programmed HDFlash devices.

ST72F361 FLASH devices are shipped to customers with a default content (FFh), while ROM factory coded parts contain the code supplied by the customer. This implies that FLASH devices have to be configured by the customer using the Option Bytes while the ROM devices are factory-configured.

## **14.1 FLASH OPTION BYTES**

The option bytes allows the hardware configuration of the microcontroller to be selected. They have no address in the memory map and can be accessed only in programming mode (for example using a standard ST7 programming tool). The default content of the FLASH is fixed to FFh. To program directly the FLASH devices using ICP, FLASH devices are shipped to customers with a reserved internal clock source enabled. In masked ROM devices, the option bytes are fixed in hardware by the ROM code (see option list).

#### **OPTION BYTE 0**

OPT7 = **WDGHALT** Watchdog reset on HALT This option bit determines if a RESET is generated when entering HALT mode while the Watchdog is active.

0: No Reset generation when entering Halt mode

1: Reset generation when entering Halt mode

OPT6 = **WDGSW** Hardware or software watchdog This option bit selects the watchdog type.

0: Hardware (watchdog always enabled)

1: Software (watchdog to be enabled by software)

OPT5 = Reserved, must be kept at default value.

#### OPT4 = **LVD** Voltage detection

This option bit enables the voltage detection block (LVD).

Selected Low Voltage Detector	VD
LVD Off	1
LVD On	0

#### OPT3 = **PLL OFF** *PLL activation*

This option bit activates the PLL which allows multiplication by two of the main input clock frequency. The PLL is guaranteed only with an input frequency between 2 and 4 MHz.

0: PLL x2 enabled

1: PLL x2 disabled

**Caution**: The PLL can be enabled only if the "OSC RANGE" (OPT11:10) bits are configured to "MP - 2~4 MHz". Otherwise, the device functionality is not guaranteed.

	STATIC OPTION BYTE 0           7         0						7	STATIC OPTION BYTE 1 7						0			
	WDG		ved		DFF	Pł	G	۳	AFI_	MAP	OSC <sup>-</sup>	TYPE	OSCR	ANGE	ved	ပ	
	HALT	SW	Hese Hese	LVD	PLLO	Ľ.	1	0	FMP	1	0	1	0	1	0	Reser	RST
De- fault(*)	1	1	1	1	1	1	1	1	1	1	1	0	1	1	1	1	

(\*): Option bit values programmed by ST

## FLASH OPTION BYTES (Cont'd)

OPT2:1 = **PKG[1:0]** Package selection These option bits select the device package.

Selected Package	PKG			
Selected Fackage	1	0		
LQFP 64	1	х		
LQFP 44	0	1		
LQFP 32	0	0		

**Note:** Pads that are not bonded to external pins are in input pull-up configuration when the package selection option bits have been properly programmed. The configuration of these pads must be kept in reset state to avoid added current consumption.

OPT0 = **FMP\_R** Flash memory read-out protection

Read-out protection, when selected provides a protection against program memory content extraction and against write access to Flash memory. Erasing the option bytes when the FMP\_R option is selected causes the whole user memory to be erased first, and the device can be reprogrammed. Refer to Section 4.3.1 and the *ST7 Flash Programming Reference Manual* for more details.

0: Read-out protection enabled

1: Read-out protection disabled

## **OPTION BYTE 1**

#### OPT7:6 = AFI\_MAP[1:0] AFI Mapping

These option bits allow the mapping of some of the Alternate Functions to be changed.

AFI Mapping 1	AFI_MAP(1)
T16_OCMP1 on PD3 T16_OCMP2 on PD5 T16_ICAP1 on PD4 LINSCI2_SCK not available LINSCI2_TDO not available LINSCI2_RDI not available	0
T16_OCMP1 on PB6 T16_OCMP2 on PB7 T16_ICAP1 on PC0 LINSCI2_SCK on PD3 LINSCI2_TDO on PD5 LINSCI2_RDI on PD4	1

AFI Mapping 0	AFI_MAP(0)
T16_ICAP2 is mapped on PD1	0
T16_ICAP2 is mapped on PC1	1

#### OPT5:4 = OSCTYPE[1:0] Oscillator Type

These option bits select the ST7 main clock source type.

Clock Source	OSCTYPE			
CIOCK Source	1	0		
Resonator Oscillator	0	0		
Reserved	0	1		
Reserved internal clock source (used only in ICC mode)	1	0		
External Source	1	1		

#### OPT3:2 = OSCRANGE[1:0] Oscillator range

If the resonator oscillator type is selected, these option bits select the resonator oscillator. This selection corresponds to the frequency range of the resonator used. If external source is selected with the OSCTYPE option, then the OSCRANGE option must be selected with the corresponding range.

т.	vp. Freq. Range	OSCRANGE			
	p. rieq. nalige	1	0		
LP	1~2 MHz	0	0		
MP	2~4 MHz	0	1		
MS	4~8 MHz	1	0		
HS	8~16 MHz	1	1		

#### OPT1 = Reserved

#### OPT0 = **RSTC** RESET clock cycle selection

This option bit selects the number of CPU cycles inserted during the RESET phase and when exiting HALT mode. For resonator oscillators, it is advised to select 4096 due to the long crystal stabilization time.

0: Reset phase with 4096 CPU cycles

1: Reset phase with 256 CPU cycles

## **14.2 TRANSFER OF CUSTOMER CODE**

Customer code is made up of the ROM/FAS-TROM contents and the list of the selected options (if any). The ROM/FASTROM contents are to be sent on diskette, or by electronic means, with the S19 hexadecimal file generated by the development tool. All unused bytes must be set to FFh.

The selected options are communicated to STMicroelectronics using the correctly completed OPTION LIST appended.

Refer to application note AN1635 for information on the counter listing returned by ST after code has been transferred.

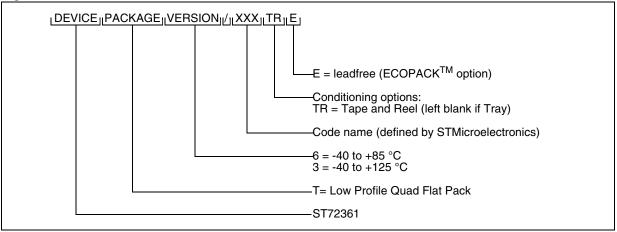

The STMicroelectronics Sales Organization will be pleased to provide detailed information on contractual points.

# **15 DEVELOPMENT TOOLS**

Development tools for the ST7 microcontrollers include a complete range of hardware systems and software tools from STMicroelectronics and thirdparty tool suppliers. The range of tools includes solutions to help you evaluate microcontroller peripherals, develop and debug your application, and program your microcontrollers.

#### 15.0.1 Evaluation Tools and Starter Kits

ST offers complete, affordable **starter kits** and full-featured **evaluation boards** that allow you to evaluate microcontroller features and quickly start developing ST7 applications. Starter kits are complete, affordable hardware/software tool packages that include features and samples to help you quickly start developing your application. ST evaluation boards are open-design, embedded systems, which are developed and documented to serve as references for your application design. They include sample application software to help you demonstrate, learn about and implement your ST7's features.

### 15.0.2 Development and Debugging Tools

Application development for ST7 is supported by fully optimizing **C Compilers** and the **ST7 Assembler-Linker** toolchain, which are all seamlessly integrated in the ST7 integrated development environments in order to facilitate the debugging and fine-tuning of your application. The Cosmic C Compiler is available in a free version that outputs up to 16K of code. The range of hardware tools includes cost effective **ST7-DVP3 series emulators**. These tools are supported by the **ST7 Toolset** from STMicroelectronics, which includes the STVD7 integrated development environment (IDE) with high-level language debugger, editor, project manager and integrated programming interface.

#### 15.0.3 Programming Tools

During the development cycle, the **ST7-DVP3** and **ST7-EMU3 series emulators** and the **RLink** provide in-circuit programming capability for programming the Flash microcontroller on your application board.

ST also provides dedicated a low-cost dedicated in-circuit programmer, the **ST7-STICK**, as well as **ST7 Socket Boards** which provide all the sockets required for programming any of the devices in a specific ST7 sub-family on a platform that can be used with any tool with in-circuit programming capability for ST7.

For production programming of ST7 devices, ST's third-party tool partners also provide a complete range of gang and automated programming solutions, which are ready to integrate into your production environment.

For additional ordering codes for spare parts, accessories and tools available for the ST7 (including from third party manufacturers), refer to the online product selector at www.st.com/mcu.

## 15.0.4 Order Codes for ST72361 Development Tools

#### Table 34. Development Tool Order Codes for the ST72361 Family

	In-circuit Debugger		Program	ning Tool
MCU	Starter Kit with Demo Board	Emulator	In-circuit Programmer	ST7 Socket Board <sup>6)</sup>
ST72361	ST72F36X-SK/RAIS <sup>1)</sup>	ST7MDT25-DVP3 <sup>2)</sup>	ST7-STICK <sup>3)4)</sup> STX-RLINK <sup>5)</sup>	ST7SB25 <sup>3)</sup>

#### Notes:

1. In-circuit programming only. In-circuit debugging is not yet supported for HDFlash devices without debug module such as the ST72F36x.

2. Requires optional connection kit. See "How to order and EMU or DVP" for connection kit ordering information in ST product and tool selection guide

3. Add suffix /EU, /UK or /US for the power supply for your region

- 4. Parellel port connection to PC
- 5. USB connection to PC

6. Socket boards complement any tool with ICC capabilities (ST7-STICK, InDART, RLINK, DVP3, EMU3, etc.)

## **16 IMPORTANT NOTES**

### **16.1 ALL DEVICES**

#### 16.1.1 RESET Pin Protection with LVD Enabled

As mentioned in note 2 below Figure 112 on page 199, when the LVD is enabled, it is recommended not to connect a pull-up resistor or capacitor. A 10nF pull-down capacitor is required to filter noise on the reset line.

# 16.1.2 Clearing Active Interrupts Outside Interrupt Routine

When an active interrupt request occurs at the same time as the related flag or interrupt mask is being cleared, the CC register may be corrupted.

#### Concurrent interrupt context

The symptom does not occur when the interrupts are handled normally, that is, when:

- The interrupt request is cleared (flag reset or interrupt mask) within its own interrupt routine
- The interrupt request is cleared (flag reset or interrupt mask) within any interrupt routine
- The interrupt request is cleared (flag reset or interrupt mask) in any part of the code while this interrupt is disabled

If these conditions are not met, the symptom can be avoided by implementing the following sequence:

Perform SIM and RIM operation before and after resetting an active interrupt request

Example:

SIM

reset flag or interrupt mask

RIM

#### Nested interrupt context

The symptom does not occur when the interrupts are handled normally, that is, when:

- The interrupt request is cleared (flag reset or interrupt mask) within its own interrupt routine
- The interrupt request is cleared (flag reset or interrupt mask) within any interrupt routine with higher or identical priority level
- The interrupt request is cleared (flag reset or interrupt mask) in any part of the code while this interrupt is disabled

If these conditions are not met, the symptom can be avoided by implementing the following sequence:

PUSH CC

SIM

reset flag or interrupt mask POP CC

#### 16.1.3 External Interrupt Missed

To avoid any risk of generating a parasitic interrupt, the edge detector is automatically disabled for one clock cycle during an access to either DDR and OR. Any input signal edge during this period will not be detected and will not generate an interrupt.

This case can typically occur if the application refreshes the port configuration registers at intervals during runtime.

#### Workaround

The workaround is based on software checking the level on the interrupt pin before and after writing to the PxOR or PxDDR registers. If there is a level change (depending on the sensitivity programmed for this pin) the interrupt routine is invoked using the call instruction with three extra PUSH instructions before executing the interrupt routine (this is to make the call compatible with the IRET instruction at the end of the interrupt service routine).

But detection of the level change does ensure that edge occurs during the critical 1 cycle duration and the interrupt has been missed. This may lead to occurrence of same interrupt twice (one hardware and another with software call).

To avoid this, a semaphore is set to '1' before checking the level change. The semaphore is changed to level '0' inside the interrupt routine. When a level change is detected, the semaphore status is checked and if it is '1' this means that the last interrupt has been missed. In this case, the interrupt routine is invoked with the call instruction.

There is another possible case, that is, if writing to PxOR or PxDDR is done with global interrupts disabled (interrupt mask bit set). In this case, the semaphore is changed to '1' when the level change is detected. Detecting a missed interrupt is done after the global interrupts are enabled (interrupt mask bit reset) and by checking the status of the semaphore. If it is '1' this means that the last interrupt was missed and the interrupt routine is invoked with the call instruction.

To implement the workaround, the following software sequence is to be followed for writing into the PxOR/PxDDR registers. The example is for Port PF1 with falling edge interrupt sensitivity. The

#### **IMPORTANT NOTES** (Cont'd) software sequence is given for both cases (global interrupt disabled/enabled). Case 1: Writing to PxOR or PxDDR with Global Interrupts Enabled: LD A,#01 LD sema,A ; set the semaphore to '1' LD A, PFDR AND A,#02 LD X.A ; store the level before writing to PxOR/PxDDR LD A,#\$90 LD PFDDR,A ; Write to PFDDR LD A,#\$ff LD PFOR,A ; Write to PFOR LD A, PFDR AND A,#02 LD Y,A ; store the level after writing to PxOR/PxDDR LD A.X ; check for falling edge cp A,#02 irne OUT TNZ Y irne OUT LD A,sema ; check the semaphore status if edge is detected CP A,#01 irne OUT call call\_routine; call the interrupt routine OUT:LD A,#00 LD sema,A .call routine ; entry to call\_routine PUSH A PUSH X PUSH CC .ext1 rt ; entry to interrupt routine LD A,#00 LD sema,A IRET Case 2: Writing to PxOR or PxDDR with Global Interrupts Disabled: SIM ; set the interrupt mask LD A, PFDR

LD X.A ; store the level before writing to PxOR/PxDDR LD A,#\$90 LD PFDDR,A; Write into PFDDR LD A,#\$ff LD PFOR,A : Write to PFOR LD A, PFDR AND A,#\$02 LD Y,A ; store the level after writing to PxOR/ **PxDDR** LD A.X ; check for falling edge cp A,#\$02 irne OUT TNZ Y irne OUT LD A,#\$01 LD sema, A ; set the semaphore to '1' if edge is detected RIM ; reset the interrupt mask LD A, sema ; check the semaphore status CP A,#\$01 irne OUT call call\_routine; call the interrupt routine RIM OUT: RIM JP while loop .call routine ; entry to call routine PUSH A PUSH X PUSH CC .ext1\_rt ; entry to interrupt routine LD A,#\$00 LD sema,A IRET **16.1.4 Unexpected Reset Fetch** If an interrupt request occurs while a "POP CC" in-

If an interrupt request occurs while a "POP CC" instruction is executed, the interrupt controller does not recognise the source of the interrupt and, by default, passes the RESET vector address to the CPU.

## Workaround

To solve this issue, a "POP CC" instruction must always be preceded by a "SIM" instruction.

AND A,#\$02

#### IMPORTANT NOTES (Cont'd)

# 16.1.5 Header Time-out Does Not Prevent Wake-up from Mute Mode

Normally, when LINSCI is configured in LIN slave mode, if a header time-out occurs during a LIN header reception (that is, header length > 57 bits), the LIN Header Error bit (LHE) is set, an interrupt occurs to inform the application but the LINSCI should stay in mute mode, waiting for the next header reception.

#### **Problem Description**

The LINSCI sampling period is Tbit / 16. If a LIN Header time-out occurs between the 9th and the 15th sample of the Identifier Field Stop Bit (refer to Figure 132), the LINSCI wakes up from mute mode. Nevertheless, LHE is set and LIN Header Detection Flag (LHDF) is kept cleared.

In addition, if LHE is reset by software before this 15th sample (by accessing the SCISR register and

#### Figure 132. Header Reception Event Sequence

reading the SCIDR register in the LINSCI interrupt routine), the LINSCI will generate another LINSCI interrupt (due to the RDRF flag setting).

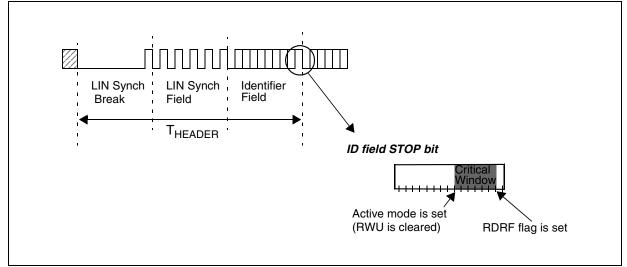

#### Impact on application

Software may execute the interrupt routine twice after header reception.

Moreover, in reception mode, as the receiver is no longer in mute mode, an interrupt will be generated on each data byte reception.

#### Workaround

The problem can be detected in the LINSCI interrupt routine. In case of timeout error (LHE is set and LHLR is loaded with 00h), the software can check the RWU bit in the SCICR2 register. If RWU is cleared, it can be set by software. Refer to Figure 133 on page 221. Workaround is shown in bold characters.

## IMPORTANT NOTES (Cont'd)

### Figure 133.LINSCI Interrupt Routine

```
@interrupt void LINSCI_IT ( void ) /* LINSCI interrupt routine */
{
     /* clear flags */
     SCISR buffer = SCISR;
     SCIDR buffer = SCIDR;
     if ( SCISR buffer & LHE )/* header error ? */
     {
           if (!LHLR) /* header time-out? */
           {
                 if ( !(SCICR2 & RWU) )/* active mode ? */
                 {
                        _asm("sim");/* disable interrupts */
                        SCISR;
                        SCIDR;/* Clear RDRF flag */
                        SCICR2 |= RWU; /* set mute mode */
                        SCISR;
                        SCIDR; /* Clear RDRF flag */
                        SCICR2 |= RWU;/* set mute mode */
                        asm("rim");/* enable interrupts */
                 }
           }
     }
}
                                                    Example using Cosmic compiler syntax
```

#### **16.2 FLASH/FASTROM DEVICES ONLY**

#### 16.2.1 LINSCI Wrong Break Duration

### SCI mode

A single break character is sent by setting and resetting the SBK bit in the SCICR2 register. In some cases, the break character may have a longer duration than expected:

- 20 bits instead of 10 bits if M = 0
- 22 bits instead of 11 bits if M = 1

In the same way, as long as the SBK bit is set, break characters are sent to the TDO pin. This may lead to generate one break more than expected.

#### Occurrence

The occurrence of the problem is random and proportional to the baud rate. With a transmit frequency of 19200 baud ( $f_{CPU} = 8 \text{ MHz}$  and SCIBRR = 0xC9), the wrong break duration occurrence is around 1%.

#### Workaround

5/

If this wrong duration is not compliant with the communication protocol in the application, software can request that an Idle line be generated before the break character. In this case, the break duration is always correct assuming the application is not doing anything between the idle and the break. This can be ensured by temporarily disabling interrupts.

The exact sequence is:

- Disable interrupts
- Reset and Set TE (IDLE request)
- Set and Reset SBK (Break Request)
- Re-enable interrupts

#### LIN mode

If the LINE bit in the SCICR3 is set and the M bit in the SCICR1 register is reset, the LINSCI is in LIN master mode. A single break character is sent by setting and resetting the SBK bit in the SCICR2 register. In some cases, the break character may have a longer duration than expected:

- 24 bits instead of 13 bits

## IMPORTANT NOTES (Cont'd)

#### Occurrence

The occurrence of the problem is random and proportional to the baud rate. With a transmit frequency of 19200 baud ( $f_{CPU} = 8$  MHz and SCIBRR = 0xC9), the wrong break duration occurrence is around 1%.

#### Analysis

The LIN protocol specifies a minimum of 13 bits for the break duration, but there is no maximum value. Nevertheless, the maximum length of the header is specified as  $(14+10+10+1) \times 1.4 = 49$  bits. This is composed of:

- the synch break field (14 bits)
- the synch field (10 bits)
- the identifier field (10 bits)

Every LIN frame starts with a break character. Adding an idle character increases the length of each header by 10 bits. When the problem occurs, the header length is increased by 11 bits and becomes ((14+11)+10+10+1) = 45 bits.

To conclude, the problem is not always critical for LIN communication if the software keeps the time between the sync field and the ID smaller than 4 bits, that is,  $208\mu s$  at 19200 baud.

The workaround is the same as for SCI mode but considering the low probability of occurrence (1%), it may be better to keep the break generation sequence as it is.

#### 16.2.2 16-bit and 8-bit Timer PWM Mode

In PWM mode, the first PWM pulse is missed after writing the value FFFCh in the OC1R or OC2R register.

#### **16.3 ROM DEVICES ONLY**

# 16.3.1 16-bit Timer PWM Mode Buffering Feature Change

In all devices, the frequency and period of the PWM signal are controlled by comparing the counter with a 16-bit buffer updated by the OCiHR and OCiLR registers. In ROM devices, contrary to the description in Section 10.5.3.5 on page 102, the output compare function is not inhibited after a write instruction to the OCiHR register. Instead the buffer update at the end of the PWM period is inhibited until OCiLR is written. This improved buffer handling is fully compatible with applications written for Flash devices.

# **17 REVISION HISTORY**

57

Date	Revision	Main changes
04-Oct-2005	1	Initial revision
26-Sep-2006	2	Changed note in "Device Summary" on page 1 Changed Section 10.6.3.3 on page 113 Changed "FASTROM Factory Coded Device Types" on page 215 Deleted Section 15.1.5 "Clearing active interrupts outside interrupt routine" (text already ex- ists in Section 16.1.2 on page 218) Added Section 16.1.5 on page 220 Replaced TQFP with LQFP packages throughout document Changed Section 12.12.1 on page 202 Changed Section 9.2.1 on page 46 Changed title of Section 9.6 on page 50 from "I/O Port Implementation" to "I/O Port Register Configurations" Corrected name of bit 5 in SPICSR register in Table 21 on page 120 Changed Section 12.5.4 on page 188 Added links to Table 32 and Table 33 in Section 12.8.3 on page 192 Removed EMC protection circuitry in Figure 113 on page 199 (device works correctly with- out these components) Changed AFI mapping for "OPTION BYTE 1" on page 211 Changed title of Figure 124 on page 208 Changed title of Figure 125 on page 208 Changed title of Figure 125 on page 208 Changed Figure 128 on page 214 Replaced "Flash Memory" with "Memory" as column heading in Figure 127 on page 212 and Figure 131 on page 215 Changed Section 15 on page 217 Added Table 34 on page 217 Removed automotive part numbers, see separate ST72361-auto datasheet
