

SINGLE-CHIP FM/AM TUNER WITH STEREO DECODER AND AUDIO PROCESSOR

1 FEATURES

- AM/FM TUNER FOR CAR-RADIO
- INTEGRATED TUNING PLL
- VARIABLE-BANDWITH FM IF FILTER (ISS)
- FULLY INTEGRATED FM STEREO DECODER
- FULLY INTEGRATED FM NOISE BLANKER
- HIGHLY INTEGRATED AUDIO PROCESSOR

2 DESCRIPTION

The TDA7513T is the first device for car-radio applications that combines full RF front-end functions with audio-processing capabilities.

As far as FM and AM functions are concerned, the TDA7513T features front-end processing, including the digital tuning PLL, IF processing with demodulation and variable-bandwidth IF filtering (ISS), stop station and quality detection functions, FM stereo decoding by means of a fully-integrated, adjustment-free dedicated PLL and, finally, FM noise blanking. The FM stereo decoder and noise blanker functions are realized entirely without external components.

The audio processor section comprises input se-

Figure 1. Package

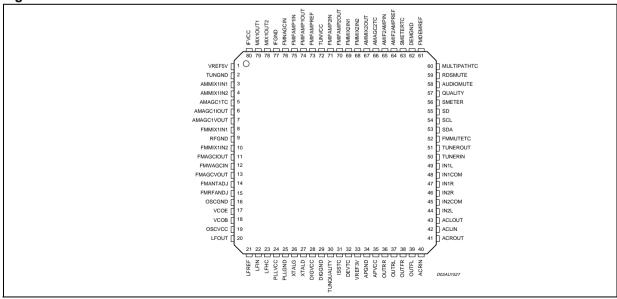

Table 1. Order Codes

Part Number	Package
TDA7513T	TQFP80

lectors for two quasi-differential external sources, volume control, tone control (bass, mid and treble), balance and fading control to drive four output channels. A soft mute function and an RDS mute function are included to handle source change as well as RDS AF search without abrupt changes in the audio level.

Most of the parameters in the front-end section are I²Cbus-driven and therefore under the control of the car-radio maker. The I²C bus allows furthermore the user to realize the full electric alignment of all the external coils, therefore removing the need for hand-made or mechanical adjustments.

Table 2. Pin Description

PIN	PIN NAME	PIN FUNCTION
1	VREF5V	5V reference
2	TUNGND	tuner general ground
3	AMMIX1IN1	am mix1 input
4	AMMIX1IN2	am mix1 input
5	AMAGC1TC	am agc1 filter capacitor
6	AMAGC1IOUT	am agc1 current output
7	AMAGC1VOUT	am agc1 voltage output
8	FMMIX1IN1	fm mix1 input
9	RFGND	rf ground
10	FMMIX1IN2	fm mix1 input
11	FMAGCIOUT	fm agc current output
12	FMWAGCIN	fm agc RF input
13	FMAGCVOUT	fm agc voltage output
14	FMANTADJ	fm antenna filter adjustment
15	FMRFANDJ	fm rf filter adjustment
16	OSCGND	vco ground
17	VCOE	am/fm vco emitter
18	VCOB	am/fm vco base
19	OSCVCC	vco supply (8V)
20	LFOUT	PLL loop filter output
21	LFREF	PLL loop filter reference
22	LFIN	PLL loop filter input
23	LFHC	PLL loop filter high-current input
24	PLLVCC	PLL back-end supply
25	PLLGND	PLL back-end ground
26	XTALG	ref osc gate
27	XTALD	ref osc drain
28	DIGVCC	digital dirty supply (8V)
29	DIGGND	digital ground
30	TUNQUALITY	tuner combined output of multipath and adjacent channel detectors
31	ISSTC	ISS time constant
32	DEVTC	deviation detector time constant
33	VREF3V	3V reference
34	APGND	audio processor/stereo decoder ground
35	APVCC	audio processor/stereo decoder supply (8V)
36	OUTRR	audio out
37	OUTRL	audio out
38	OUTFR	audio out
39	OUTFL	audio out
40	ACRIN	ac coupling right input

Table 2. Pin Description (continued)

PIN	PIN NAME	PIN FUNCTION
41	ACROUT	ac coupling right output
42	ACLIN	ac coupling left input
43	ACLOUT	ac coupling left output
44	IN2L	audio in2 left
45	IN2COM	audio in2 common
46	IN2R	audio in2 right
47	IN1R	audio in1 right
48	IN1COM	audio in1 common
49	IN1L	audio in1 left
50	TUNERIN	am audio/fm mpx input
51	TUNEROUT	am audio/fm mpx output
52	FMMUTETC	fm muting time constant capacitor
53	SDA	I2C bus data
54	SCL	I2C bus clock
55	SD	am/fm station detector output
56	SMETER	am/fm smeter output
57	QUALITY	quality output
58	AUDIOMUTE	audio mute control
59	RDSMUTE	rds mute control
60	MULTIPATHTC	multipath detector time constant
61	FMDEMREF	fm demodulator reference capacitor
62	DEMGND	fm demodulator ground
63	SMETERTC	am/fm smeter filtering capacitor
64	AMIF2AMPREF	am if2 amp feedback capacitor
65	AMIF2AMPIN	am if2 amp input
66	AMAGC2TC	am agc2 filter capacitor
67	AMMIX2OUT	am mix2 single-ended output
68	FMMIX2IN2	fm mix2 input
69	FMMIX2IN1	fm mix2 input
70	FMIFAMP2OUT	fm if1 amp2 output
71	FMIFAMP2IN	fm if1 amp2 input
72	TUNVCC	tuner general supply (8V)
73	FMIFAMPREF	fm if1 amps reference capacitor
74	FMIFAMP1OUT	fm if1 amp1 output
75	FMIFAMP1IN	fm if1 amp1 input
76	FMNAGCIN	fm agc IF input
77	IFGND	if1 ground
78	MIX1OUT2	am/fm mix1 output
79	MIX1OUT1	am/fm mix1 output
80	IFVCC	if1 supply (8V)

5 FUNCTIONAL DESCRIPTION

5.1 FM Section

5.1.1 Mixer1. AGC and 1st IF

Mixer1 is a wide dynamic range stage with low noise and large input signal performance. The mixer1 tank center frequency can be adjusted by software (IF1T). The AGC operates on different sensitivities and bandwidths (FMAGC) in order to improve the input sensitivity and dynamic range (keyed AGC). The output signals of AGC are controlled voltage and current for preamplifier and prestage P-I-N diode attenuator (see Figure 5). Two 10.7MHz amplifiers (IFG1 - fixed gain - and IFG2 - programmable) correct the IF ceramic insertion loss.

5.1.2 Mixer2, Limiter and Demodulator

In this 2nd mixer stage the first 10.7MHz IF is converted into the second 450kHz IF. A multi-stage limiter generates signals for the complete integrated demodulator without external tank. MPX output DC offset compensation is possible via software.

5.1.3 Quality Detection and ISS (see Figure 3) Fieldstrength

Parallel to the mixer2 input a 10.7MHz limiter generates a signal for the digital IF counter and a field-strength output signal. This internal unfiltered fieldstrength is used for adjacent channel and multipath detection. The behaviour of this output signal can be corrected for DC offset (SL). The internally generated unfiltered fieldstrength is filtered at pin #SMETERTC and used for softmute function, FM AGC keying and generation of ISS filter switching signal for weak input level (sm).

5.1.4 Adjacent Channel Detector

The input of the adjacent channel detector is AC coupled to the internal unfiltered fieldstrength. A programmable and configurable highpass or bandpass filter (ACF) and amplifier (ACG) followed by a rectifier measure the adjacent channel content. This voltage is compared with an adjustable threshold (ACWTH, ACNTH) comparator (comparator1). The output signal of this comparator generates a DC level at PIN15 with a programmable time constant. Time constant control (TISS) for the adjacent channel is made by linearly charging and discharging an external capacitor following. The charge current is fixed and the discharge current is controlled by I²C bus. This level produces digital signals (ac, ac+) after comparing by the following comparator4. The adjacent channel information after filtering and rectification is available as analog output on pin #TUNQUALITY (the gain can be selected via I²C bus) in combination with multipath content information. It is possible to enable adjacent channel content information output only via I²C bus control.

5.1.5 Multipath Detector

The input of the multipath detector is AC coupled to the internal unfiltered fieldstrength. A programmable band-pass filter (MPF) and amplifier (MPG) followed by a rectifier measures the multipath content. This voltage is compared with an adjustable threshold (MPTH) comparator (comparator2). The output signal of this comparator2 is used to disable the adjacent channel detector control of the ISS filter in case of strong multipath, which would otherwise result in bandwidth reduction because of the multipath-induced high-frequency content of the fieldstrength signal. The multipath detector influence on the adjacent channel detector is selectable by I²C bus (MPOFF). The multipath information after filtering and rectification is available as analog output on pin #TUNQUALITY (the gain can be selected via I²C bus) in combination with the adjacent channel content information. It is possible to enable multipath content information output only via I²C bus control.

5.1.6 450kHz IF Narrow Bandpass Filter (ISS filter)

The device features an additional automatically selectable IF narrow bandpass filter for suppression noise and adjacent channel signals. This narrow filter has three switchable bandwidth positions: narrow range (80kHz), mid range (120kHz) and weather band (30kHz). When the ISS filter is not inserted the IF bandwidth (wide range) is defined only by the ceramic filter chain. The filter is switched in after mixer2 before the 450kHz limiter stage. The centre frequency can be finely adjusted (AISS) by software.

5.1.7 Deviation Detector

In order to avoid excessive audio distortion the narrow ISS filter is switched OFF when overdeviation of the incoming signal is detected. The demodulator output signal is low-pass filtered and rectified to generate a DC level in an external capacitor through a software-controlled current (TDEV). This level is compared with a programmable threshold (DWTH, DTH) comparator (comparator3) to generate two digital signals (dev, dev+).

5.1.8 ISS Switch Logic

All digital signals coming from adjacent channel detector, deviation detector and softmute are combined in a decision matrix to generate the control signals for the ISS filter switch. The IF bandpass switch mode can be also controlled by software (ISSON, ISS30, ISS80, ISSCTL). The switch-on of the IF bandpass can be further controlled from the outside by manipulation of the voltage at pin #ISSTC. Two application modes are available (APPM). The conditions are described in table 1.

5.1.9 Soft Mute Control

The external fieldstrength signal at pin #SMETERTC is the reference for MPX mute control. The start point and mute depth are programmable over a wide range. The time constant is defined by the external capacitor connected to pin #FMMUTETC.

Additionally adjacent channel mute function is supported. A software-configurable highpass / bandpass filter centered at about 100kHz followed by an amplifier and a peak rectifier generates adjacent noise information starting from the MPX output; the information is acted upon with the same time constant as the softmute by the MPX muting circuit. The adjacent channel mute starting point, slope and depth are I²C bus programmable.

5.1.10 Station Detector and Seek Stop

A station detection function is provided for easy seek stop operation. The unfiltered fieldstrength signal is compared with a programmable threshold and the result (logic '1' if the current station strength is higher than the threshold) is combined by an AND gate with the IF counter output (logic '1' if the current channel is centered within a programmable window around the desired frequency). The result is available on pin #SD for direct connection to the microprocessor. Channel quality assessment for RDS Alternate Frequency operation makes use of the SD signal in conjunction with analog information on adjacent channel and multipath content on pin #TUNQUALITY and channel noise (furtherly combined with multipath content information) on pin #QUALITY.

47/

5.2 AM Section

The upconversion mixer1 is combined with a gain control circuit 1 sensing three input signals: ultra-narrow band information (from the IF2 amplifier input - pin #AMIF2AMPIN), narrow-band information (from the mixer2 input - pin #AMMIX2IN) and wide band information (from the mixer1 input - pins #AMMIX1IN+ and #AMMIX1IN-). This gain control circuit generates two output signals: a current for P-I-N diode attenuation and a voltage for the external preamplifier cascode upper base. It is possible to put in a separate narrow bandpass filter before mixer2 at PIN 58. The intervention point for first AGC on all three bands is programmable by software.

The oscillator frequency for mixer1 is generated by dividing the FM VCO frequency (AMD) by 6, 8 and 10 (6 for Japan applications, 8 for Eastern European applications, 10 for Western European and North American operation).

In mixer2 the IF1 is downconverted into the 450kHz IF2. The gain of mixer2 is reduced by the 2nd AGC after the gain of the subsequent IF2 amplifier has been reduced by 30dB. The mixer2 tank center frequency is software-adjustable (IF2T).

After channel selection is done by the ceramic filter, a 450kHz amplifier with a gain control is included. The gain is controlled by the AGC2 loop over a 30dB range; the full gain with no AGC applied is programmable.

The AM demodulation is made by multiplication of the IF2 amplifier output by the amplified and limited signal coming from the IF2 amplifier input, thus making the demodulation process inherently linear.

The demodulated audio signal is low-passed by the capacitor at pin #AMAGC2TC to produce the DC AGC2 voltage. The low-pass time constant is switchable by a ratio of 30 in order to reduce the settling time of the AGC2 in 'seek' mode (AMSEEK).

The FM 450kHz limiter is used to generate the square wave needed by the AM demodulator, a field-strength indication and to feed the AM IF counter. The fieldstrength information is generated mainly from the narrow-band signal at the input of the IF2 amplifier; since the dynamic range at that input is limited by the AGC2 action, a fieldstrength extension is made adding the contribution of the signal at the input of mixer2. Since the bandwidth there is very large, though, the latter contribution is enabled only if the strength of the narrow-band signal is higher than an internally defined threshold. The fieldstrength signal must be low-passed to remove audio content and this is done by use of the capacitor at pin #SMETERTC with an I²C bus programmable internal resistor. The value of the capacitor is determined for correct FM operation; the value of the internal resistor for AM is selectable in order to make the AM time constant suitable for AM operation.

A station detection function is provided for easy seek stop operation. The fieldstrength signal is compared with a programmable threshold and the result (logic '1' if the current station strength is higher than the threshold) is combined by an AND gate with the IF counter output (logic '1' if the current channel is centered within a programmable window around the desired frequency). The result is available on pin #SD for direct connection to the microprocessor.

5.3 PLL and IF Counter Section

The IC contains a frequency synthesizer and a loop filter for the radio tuning system. Only one VCO is required to build a complete PLL system for FM and AM upconversion. For auto search stop operation an IF counter system is available.

5.3.1 PLL Frequency Synthesizer Block

The counter works in a two stages configuration. The first stage is a swallow counter with a two-modulus (32/33) precounter. The second stage is an 11-bit programmable counter. The circuit receives the scaling factors for the programmable counters and the values of the reference frequency via I²C bus. The reference frequency is generated by an adjustable internal (XTAL) oscillator followed by the reference divider. The reference and step-frequencies are independently selectable (RC, PC). The phase-frequency detector outputs switches the programmable current source. The loop filter integrates the latter to a DC voltage. The current source values is programmable with 6 bits received via I2C bus (A, B, CURRH, LPF). To minimize the noise induced by the digital part of the system, a special guard area is implemented. The loop gain can be adjusted for different conditions by setting the current values of the chargepump generator.

5.3.2 Frequency Generation for Phase Comparison

The VCO signal is fed to a two-modulus counter (32/33) prescaler, which is controlled by a 5-bit divider (A). A 5-bit register (PC0 to PC4) controls this divider. The output of the prescaler is connected to an 11-bit divider (B), controlled by an 11-bit PC register (PC5 to PC15).

The following expressions relate the divider output frequency (f_{SYN} , forced by the loop to equal the reference frequency at the phase comparator input f_{REF}) to the VCO frequency (f_{VCO}) and to the crystal oscillator frequency (f_{XTAL}):

 $f_{XTAL} = (R+1) \times f_{REF}$

 $f_{VCO} = [33 \times A + (B + 1 - A) \times 32] \times f_{REF}$

 $f_{VCO} = (32 \times B + A + 32) \times f_{REF}$

Important: For correct operation: A \leq 32; B \geq A

5.3.3 Three State Phase Comparator

The phase comparator generates a phase error signal according to phase difference between f_{SYN} and f_{REF}. This phase error signal drives the charge pump current generator.

5.3.4 Charge Pump Current Generator

This system generates correction current pulses with a polarity and a duration dictated by the phase error signal. The current absolute values are programmable through register A for high current and register B for low current.

The charge pump operates in high current mode when the phase difference between between f_{SYN} and f_{REF} is high. The switch back to low current mode can be done either automatically as a function of the inlock detector output (setting bit LDENA to "1") or via software.

After reaching a phase difference equivalent to 10-40 ns (programmable) and a delay multiple of 1/f_{REF}, the chargepump is forced in low current mode. A new PLL divider programming by I²C bus will switch the chargepump into high current mode.

A few programmable phase errors (D0, D1) are available for inlock detection. The count of detected inlock informations to release the inlock signal is adjustable (D2, D3), to avoid switching to low current during a frequency jump.

5.3.5 Low Noise CMOS Op-amp

An internal voltage divider at pin #LFREF is connected to the positive input of the low noise op-amp. The charge pump output is connected to the negative input. This internal amplifier in cooperation with external components provides the active loop filter. Only one loop filter connection is provided because the same reference frequency is used for both AM and FM operation. The pin #LFHC is connected in such a way as to partially shunt the loop filter in order to decrease the time constant of the filter itself during jumps with high current mode activated.

5.3.6 IF Counter Block

The input signal for FM and AM has the same structure although FM IF is measured at IF1 (10.7MHz) and AM IF is measured at IF2 (450kHz). The degree of integration is adjustable to up to eight different measuring cycle times. The tolerance of the accepted count value is adjustable to reach the optimum compromise between search speed and evaluation precision.

T center frequency of the measured count value is adjustable to fit the IF-filter tolerance.

5.3.7 The IF-Counter Mode

The IF counter works in 2 modes controlled by the IFCM register.

5.3.8 Sampling Timer

A 14-bit programmable (IRC) sampling timer generates the gate signal for the main counter. In FM mode a 6.25kHz frequency reference is generated for this purpose, whereas in AM mode this reference becomes 1kHz. These reference frequencies are further divided to generate the measurement time windows

(160us - 320µs ... 20.48ms for FM, 1ms - 2ms ... 128ms for AM).

5.3.9 Intermediate Frequency Main Counter

This counter is a 11 - 21-bit synchronous autoreload down counter. Five bits (CF) are programmable to allow the adjustment to the peak of the IF-filter response. The counter length is automatically adjusted to the chosen sampling time and counter mode (FM, AM).

The IF counter is also used to automatically perform the stereo decoder 456kHz VCO frequency adjustment.

At the start the counter will be loaded with a value equivalent to the expected number of zero-crossing in the sampling time window ($t_{Sample} \times f_{IF}$). If the correct frequency is applied to the IF counter input, at the end of the sampling time the main counter will have either a 0h state or a 1FFFFFh state stored.

A deviation from the expected IF will result in a difference of the counter final state from either of these values. The counter final state is then compared to either 0h or 1FFFFh minus a number of LSB's determined by the acceptable frequency window programming (EW).

If the comparison result is good the IF counter output changes from LOW to HIGH and is made available outside at the pin #SD (after a NAND operation with the signal strength evaluation circuit). The following relationships apply:

```
t_{TIM} = (IRC + 1) / f_{OSC}

t_{CNT} = (CF + 1697) / f_{IF} (FM mode)

t_{CNT} = (CF + 448) / f_{IF} (AM mode)
```

where

t_{TIM} = IF timer cycle time (sampling time) t_{CNT} = IF counter cycle time

Counting succesful:

 $t_{CNT} - t_{ERR} = t_{TIM} = t_{CNT} + t_{ERR}$

Count failed:

 $t_{TIM} > t_{CNT} + t_{ERR}$ $t_{TIM} < t_{CNT} - t_{ERR}$

where

t_{FRR} = discrimination window (controlled by the EW registers)

The IF counter can be started only by inlock information from the PLL, and it is enabled by software (IFENA).

5.3.10 Adjustment of the Measurement Time and Frequency window

The measurement precision is adjustable by controlling the width of the frequency discrimination window through control registers EW0 to EW2. The center frequency of the discrimination window is adjustable by the control register CF0 to CF4. The measurement time per cycle is adjustable by setting the registers

IFS0 - IFS2.

5.4 AUDIO PROCESSOR

5.4.1 Input Multiplexer

CD quasi differential 1

CD quasi differential 2

Stereodecoder input (for both FM and AM signals).

5.4.2 Input stages

The quasi-differential input stages (see figure 4) have been designed to cope with some CD players in the market having a significant high source impedance which affects strongly the common-mode rejection of "normal" differential input stages. The additional buffer of the CD input avoids this drawback and offers the full common-mode rejection even with those CD players. The quasi-differential input can also be used with normal stereo single-ended output signal sources such as TAPEOUT.

5.4.3 AutoZero

In order to reduce the number of pins there is no AC coupling between the In-Gain and the following stage, so that in theory any offset generated by or before the In-Gain stage would be transferred or even amplified to the output. To avoid this undesired situation a special offset cancellation stage called AutoZero is implemented. This stage is located before the Volume block to eliminate all offsets generated by the Stereodecoder, the Input Stage and the In-Gain stage (please note that externally generated offsets, e.g. those generated because of leakage current into the coupling capacitors, are not cancelled).

The auto-zeroing is started every time the APSD data byte 0 is selected and takes a maximum time of 0.6ms. The rationale behind this choice is that the APSD byte encodes the signal source selection, and auto-zero ought to be performed every time a new source is selected. To avoid audible clicks the audio-processor is muted before the volume stage during this time.

5.4.4 AutoZero Remain

In some cases, for example if the uP is executing a refresh cycle of the I²C bus programming, it is not necessary to start a new AutoZero action because no new source is selected and an undesired mute would appear at the outputs. For such applications the device can be switched in the "AutoZero Remain mode" (Bit 6 of the APSD subaddress byte). If this bit is set to high, the APSD data byte 0 can be loaded without invoking the AutoZero and the old adjustment value remains.

5.4.5 Softmute

The digitally controlled softmute stage allows signal muting and unmuting with a I²C bus programmable slope. The mute process can either be activated by pin #AUDIOMUTE or I²C bus. The slope is realized in a special S-shaped curve so as to slowly mute in the critical regions (see figure 5). For timing purposes the Bit 3 of the I²C bus output register is set to 1 from the start of muting until the end of unmuting.

5.4.6 BASS

There are four parameters programmable in the bass filter stage: (see figs 6, 7, 8, 9):

5.4.7 Attenuation

Figure 6 shows the attenuation as a function of frequency at a center frequency at a center frequency of 80Hz.

5.4.8 Center Frequency

Figure 7 shows the four possible center frequencies: 60,70,80 and 100Hz.

5.4.9 Quality Factors

Figure 8 shows the four possible quality factors: 1, 1.25, 1.5 and 2.

5.4.10DC Mode

In this mode the DC gain is increased by 5.1dB. In addition the programmed center frequency and quality factor is decreased by 25%: this can be used to realize different center frequencies or quality factors with respect to the values listed in the "BASS" section.

5.4.11 MID

There are 3 parameters programmable in the mid filter stage (see figs. 10, 11 & 12):

5.4.12 Attenuation

Figure 10 shows the attenuation as a function of frequency at a center frequency of 1kHz.

5.4.13 Center Frequency

Figure 11 shows the four possible center frequencies: 500Hz, 1kHz, 1.5kHz and 2kHz.

5.4.14 Quality Factor

Figure 12 shows the two possible quality factors (1 and 2) at a center frequency of 1kHz.

5.4.15TREBLE

There are two parameters programmable in the treble filter stage (see figs 13, 14):

5.4.16 Attenuation

Figure 13 shows the attenuation as a function of frequency at a center frequency of 17.5kHz.

5.4.17 Center Frequency

Figure 14 shows the four possible Center Fre-quencies: 10, 12.5, 15 and 17.5kHz.

5.4.18AC Coupling

In some applications additional signal manipulations are desired such as surround-sound processing or more extensive band equalizing. For this purpose a AC-Coupling is placed before the Speaker-attenuators, which can be activated or internally shorted by Bit7 in the APSD data byte 0. The input impedance of the AC Inputs is $25k\Omega$. The external AC coupling is advised for those applications where very low-level "pop" performance is a must.

5.4.19 Speaker Attenuator

The speaker attenuators have exactly the same structure and range as the Volume stage.

5.5 STEREODECODER

The stereodecoder part of the present device (see Fig. 15) contains all functions necessary to demodulate the MPX signal such as pilot tone-dependent MONO/STEREO switch as well as "stereoblend" and "high-cut" functions.

Stereodecoder Mute

The device has a fast and easy-to-control RDS mute function meant for "freezing" the stereo decoder status during the RDS AF check time period. When this function is invoked three effects take place:

- •1 the stereo decoder input impedance changes to infinity (condition known as high-ohmic input); this prevents the decoupling capacitor between the pins #TUNER_OUT (tuner output) and #TUNER_IN (stereo decoder input) to be discharged by a channel with a potentially different DC output for the duration of the AF check:
- •2 the stereo decoder PLL pilot detector is held at the current value;
- •3 the external capacitor of the multipath detector used inside the stereo decoder for quality control is disconnected from the dection circuit in order to make quality checking the AF faster.

The RDS mute is activated from pin #RDSMUTE in AND with Bit 0 of APSD data byte 9.

5.5.1 Stereo Decoder Input stage, Ingain + Infilter

The stereo decoder is crossed by both the FM and the AM signal: the input impedance of the pin $\#TUNER_IN$ is different between the two modes in order to allow the same external coupling components between $\#TUNER_OUT$ and $\#TUNER_IN$ to realize different filtering functions. Whilst the input impedence in FM is 100k, in AM the input impedance is decreased to $2k\Omega$: this allows the realization of typical high-pass filters with a corner frequency of 70Hz for AM and less than 5Hz for FM. The low-pass section of the typical AM transfer function is realized by use of the internal FM High-Cut filter.

The Ingain stage allows to adjust the MPX signal to a magnitude of about 1Vrms internally which is the recommended value. The 4th order input filter has a corner frequency of 80kHz and is used to attenuate spikes and nose and acts as an anti aliasing filter for the following switch capacitor filters.

5.5.2 Demodulator

In the demodulator block the left and the right channel are separated from the MPX signal. In this stage the 19 kHz pilot tone is cancelled.

To reach a good channel separation the device offers an I2C bus programmable roll-off adjustment which is able to finely compensate for the low-pass behaviour of the tuner section. An adjustment to better than 40dB channel separation is possible. The bits for this adjustment are located ogether with the fieldstrength adjustment in one byte. This gives the possibility to perform an optimization step during the production of the carradio where the channel separation in relation to the fieldstrength control are trimmed.

The setup of the Stereoblend characteristics, which is programmable in a wide range, is de-scribed in 2.8.

5.5.3 De-emphasis and Highcut.

One filter is provided to realize de-emphasis and High-Cut filtering.

The lowpass filter for the de-emphasis allows to choose between a time constant of $50\mu s$ and $75\mu s$. The filter time constant can further be controlled in both cases over the range = 2 DEEMPH. The control is automatically performed as a function of the filtered field strength level: inside the highcut control range (between VHCH and VHCL) the level is converted into a 5 bit word which drives the lowpass time constant. The FM highcut function can be switched off by I²C bus (bit 0,of APSD data byte 11). The setup of the highcut characteristics is described in 2.9.

In AM the high-cut filter can be programmed (bit 3 to 7 of APSD data byte 16) to a fixed value (inside the above-mentioned programmable range) in order to provide the desired lowpass characteristic of the AM signal.

5.5.4 PLL and Pilot Tone Detector

The PLL is tasked with locking on the 19kHz pilot tone during a stereo transmission to allow the correct demodulation. The detector enables the stereo demodulation if the pilot tone reaches the selected pilot tone threshold VPTHST. Two different thresholds are available. The detector output can be checked by reading the status byte of the TDA7407 via I²C bus.

5.5.5 Fieldstrength Control

The filtered field strength signal is fed to the stereo decoder where it can be finely adjusted and normalized so that it can be used to control the highcut and stereoblend functions. Furthermore the adjusted signal can also be used to control the noise-blanker thresholds. The unfiltered field strength meter, on the other hand, is used as input for the stereo decoder multipath detector. These additional functions are described in sections 3.3 and 4.

5.5.6 LEVEL Input and Gain

To help suppress undesired high frequency modulation of the highcut and stereoblend functions the tuner filtered field strength signal (LEVEL) is lowpassed by a combination of a 1st order RC low-pass at 53kHz (working as anti-aliasing filter) and a 1st-order switched capacitor lowpass at 2.2kHz.

The second stage is a programmable gain stage to finely adapt the LEVEL signal internally against tuner

spread (see Testmode section 5 LEVELINTERN). The gain is widely programmable in 16 steps from 0dB to 10dB (step = 0.67dB).

5.5.7 Stereoblend Control

The stereoblend control block converts the internal LEVEL voltage (LEVELINTERN) into a demodulator-compatible analog signal which is used to control the channel separation between 0dB and the maximum separation. This control range has a fixed upper limit which is the in-ternal reference voltage REF5V. The lower limit

can be programmed between 29.2% and 58% of REF5V in 4.167% steps (see figs. 14, 15).

To adjust the LEVEL voltage to the proper range two values must be defined: the LEVEL gain LG and VSBL (see fig. 15). To adjust the voltage where the full channel separation is reached (VST) the LEVEL gain L_G has to be defined. The following equation can be used to estimate the gain:

$$L_{G} = \frac{REF5V}{Fieldstrengthvoltage[STEREO]}$$

The gain L_G can be programmed with 4 bits. The MONO voltage VMO (0dB channel separation) can be chosen selecting VSBL. All the necessary internal reference voltages like REF5V are derived from a bandgap circuit, therefore they have a temperature coefficient which is practically zero.

5.5.8 Highcut Control

The highcut control setup is similar to the stereoblend control setup: the starting point VHCH can be set with 2 bits to be 42, 50, 58 or 66% of REF5V whereas the range can be set to be 17, 22, 28 or 33% of VHCH (see fig. 19).

5.6 NOISE-BLANKER

In the automotive environment the MPX signal is disturbed by spikes produced for example by the ignition and by the wiper motor. The aim of the noiseblanker part is to cancel the audible influence of these spikes. To perform this function the output of the stereodecoder is held at the curent voltage for a time between 22 and $38\mu s$ (programmable). The block diagram of the noiseblanker is shown in fig.20. In the first stage the spikes are detected but to avoid a wrong triggering on high frequency (white) noise a complex trigger desensitization control is implemented. Behind the trigger stage a pulse former generates the "blanking" pulse

5.6.1 Trigger Path

The incoming MPX signal is highpassed by a filter with a corner frequency of 140kHz, amplified and rectified. The rectified signal (RECT) is lowpassed to generate the signal PEAK. Also noise at a frequency higher than 140kHz increases PEAK. The lowpass output voltage can be adjusted by changing the noise rectifier discharge current. The PEAK voltage is fed to a threshold generator which adds to the PEAK voltage a constant voltage VTH, thus producing the trigger threshold PEAK+VTH. Both RECT and PEAK+VTH are fed to a comparator which trig-gers a re-triggerable monoflop. The monoflop output activates the sample-and-hold circuits in the signalpath for a selectable duration.

5.6.2 Automatic Noise Controlled Threshold Adjustment (ATC)

There are mainly two independent possibilities to program the trigger threshold:

- a programming the so-called "low threshold" in 8 steps;
- b programming the so-called "noise-adjusted threshold" in 4 steps

The "low threshold" is active in combination with a good MPX signal without any noise; the PEAK voltage is less than 1V. The sensitivity in this operating mode is high.

If the MPX signal is noisy the PEAK voltage increases due to the higher noise, which is also rectified. With increasing of the PEAK voltage the trigger threshold increases, too. This particular mechanism ("noise-adjusted threshold") is programmable in 4 steps.

5.7 AUTOMATIC THRESHOLD CONTROL MECHANISM

5.7.1 Automatic Threshold Control by the Stereoblend Voltage

Besides the noise-controlled threshold adjustment there is an additional possibility to influence the trigger threshold which depends on the stereoblend control.

The point where the MPX signal starts to become noisy is fixed by the RF part. Therefore also the starting point of the normal noise-controlled trigger adjustment is fixed. In some cases the behavior of the noise-blanker can be improved by increasing the threshold even in a region of higher fieldstrength. Sometimes a wrong triggering occures for the MPX signal often shows distortion in this range which can be avoided even if using a low threshold. Because of the overlap of this range and the range of the stereo/mono transition it can be controlled by stereoblend.

This threshold increase is programmable in 3 steps or switched off.

5.7.2 Over Deviation Detector

If the system is tuned to stations with a high de-viation the noiseblanker might be erroneously triggered on the higher frequencies of the modulation. To avoid this unnecessary muting of the signal, the noiseblanker offers a deviation-dependent threshold adjustment.

By rectifying the MPX signal a further signal representing the actual deviation is obtained. This is used to increase the PEAK voltage. The circuit offset, gain (and enabling) are programmable in 3 steps.

5.8 MULTIPATH DETECTOR

Using the stereo decoder multipath detector the audible effects of a multipath condition can be minimized. A multipath condition is detected by rectifying the 19kHz spectrum in the fieldstrength signal. An external capacitor is used to define the attack and decay times (see block diagram fig. 21). The pin #MULTIPATH-TC is externally connected to a capacitor of about 47nF and the MPIN signal is internally connected to the unfiltered field strength. To avoid losing the information stored in the external capacitor during AF checks but at the same time to allow some fast multipath detection capability during the same AF check period, the external capacitor is disconnected by the MP-Hold switch. This switch is controlled directly by the pin #RDSMUTE.

Moreover, selecting the "internal influence" in the configuration byte, the channel separation is automatically reduced during a multipath condition according to the voltage appearing at the pin #MULTIPATHTC.

5.8.1 Programming

To obtain a good multipath performance an adaptation is necessary. Therefore tha gain of the 19kHz bandpass is programmable in four steps as well as the rectifier gain. The attack and decay times can be set by properly choosing the value of the external capacitor.

5.9 QUALITY DETECTOR

The device offers a quality detector output voltage representing the quality of the FM reception conditions. This voltage is derived from MPX noise information and multipath information according to the following formula:

Quality = 1.6 (V_{noise} -0.8V)+ a (REF5V- V_{MPOUT})

The noise signal is the PEAK signal of the noise blanker without additional influences. The multipath information weight "a" can be programmed between 0.7 and 1.15. The circuit output pin #QUALITY is a low impedance output able to drive external circuitry as well as suitable to be simply fed to an A/D converter for RDS applications.

5.9.1 AF Search Control

The device is supplied with several functionality to support AF-checks using the stereodecoder. As already mentioned before the high ohmic mute feature at the stereo decoder input avoids any clicks during the iump condition.

It is possible at the same time to evaluate the noise- and multipath-content of the alternate frequency by

using the Quality detector output. During this time the multipath detector is automatically switched to a small time constant.

One dedicated pin (#RDSMUTE) is provided in order to separate the audioprocessor-mute and stereode-coder AF-functions.

5.10 I²C-Bus Interface

I²C bus protocol is supported. This protocol defines any device that sends data onto the bus as a transmitter, and the receiving device as the receiver.

The device that controls the transfer is a master and device being controlled is the slave. The master will always initiate data transfer and provide the clock to transmit or receive operations. The present device always acts as slave, both in transmission and in reception mode.

5.10.1 Data Transition

Data transition on the SDA line must only occur when the clock SCL is LOW. SDA transitions while SCL is HIGH will be interpreted as START or STOP condition.

5.10.2 Start Condition

A start condition is defined by a HIGH to LOW transition of the SDA line while SCL is at a stable HIGH level. This "START" condition must precede any command and initiate a data transfer onto the bus. The device continuously monitors the SDA and SCL lines for a valid START and will not response to any command if this condition has not been met.

5.10.3Stop Condition

A STOP condition is defined by a LOW to HIGH transition of the SDA while the SCL line is at a stable HIGH level. This condition terminates the communication between the devices and forces the bus interface of the device into the initial condition.

5.10.4 Acknowledge

Indicates a successful data transfer. The transmitter will release the bus after sending 8 bits of data. During the 9th clock cycle the receiver will pull the SDA line to LOW level to indicate it received the eight bits of data.

5.10.5 Data Transfer

During data transfer the device samples the SDA line on the leading edge of the SCL clock. Therefore, for proper device operation the SDA line must be stable during the SCL LOW to HIGH transition.

5.10.6 Device Addressing

To start the communication between two devices, the bus master must initiate a start instruction sequence, followed by an eight bit word corresponding to the address of the device.

The device recognizes the following two addresses:

1100010d tuner part address

1000110d stereo decoder / audio processor address (APSD)

The last bit of the start instruction defines the type of operation to be performed:

- when set to "1", a read operation is selected (data are transferred from the device to the master)
- when set to "0", a write operation is selected (data are transferred from the master to the device)

The device connected to the bus will compare its own hardwired addresses with the slave address being transmitted after detecting a START condition.

After this comparison, the device will generate an "acknowledge" on the SDA line and will perform either a read or a write operation according to the state of the R/W bit.

5.10.7 Write Operation

Following a START condition the master sends a slave address word with the R/W bit set to "0". The device will generate an "acknowledge" after this first transmission and will wait for a second word (the subaddress field).

This 8-bit address field provides an access to any of the 64 internal addresses (32 corresponding to the tuner address and 32 corresponding to the stereo decoder / audio processor address). Upon receipt of the subaddress the device will respond with an "acknowledge".

At this time, all the following words transmitted to the device will be considered as Data.

The internal address may be automatically incremented if the auto-increment mode is selected (bit S5 of the subaddress word) .

After each word has been received the device will answer with an "acknowledge".

5.10.8 Read Operation

IF the master sends a slave address word with the R/W bit set to "1", the device will transmit one 8-bit data word.

This data word content changes according to the address corresponding to the tuner or to the stereo decoder / audio processor. The information are the following:

- tuner

bit0: ISS filter, 1 = ON, 0 = OFF

bit1: ISS filter bandwidth, 1 = 80kHz, 0 = 120kHz bit2: MPOUT,1 = multipath present, 0 = no multipath
