# 128M(4Mx32) GDDR SDRAM <br> HY5DW283222BF(P) 

## Revision History

| No. | History | Draft Date | Remark |
| :---: | :--- | :---: | :---: |
| 0.1 | Defined Target Spec. | Jun. 2004 |  |
| 0.2 | 1) Changed IDD \& 500Mhz speed bin insert <br> 2) Changed tRCDWR, tWR at 450Mhz speed bin | Oct. 2004 |  |
| 1.0 | 1) Changed IDD Spec. <br> 2) Changed CAS Latency to 4 clock from 5 clock at 350MHz speed bin | Feb. 2005 |  |
| 1.1 | Added 200Mhz Speed Bin | May. 2005 |  |

## DESCRI PTI ON

The Hynix HY5DW283222 is a 134,217,728-bit CMOS Double Data Rate(DDR) Synchronous DRAM, ideally suited for the point-to-point applications which requires high bandwidth.

The Hynix 4Mx32 DDR SDRAMs offer fully synchronous operations referenced to both rising and falling edges of the clock. While all addresses and control inputs are latched on the rising edges of the CK (falling edges of the /CK), Data, Data strobes and Write data masks inputs are sampled on both rising and falling edges of it. The data paths are internally pipelined and 2-bit prefetched to achieve very high bandwidth. All input and output voltage levels are compatible with SSTL_2.

## FEATURES

- The Hynix HY5DW283222BF(P) guarantee until 200 MHz speed at DLL_off condition
- 2.5V VDD and 1.8V VDDQ +/-5\% power supply supports
- All inputs and outputs are compatible with SSTL_2 interface
- $12 \mathrm{~mm} \times 12 \mathrm{~mm}, 144$ ball FBGA with 0.8 mm pin pitch
- Fully differential clock inputs (CK, /CK) operation
- Double data rate interface
- Source synchronous - data transaction aligned to bidirectional data strobe (DQS0 ~ DQS3)
- Data outputs on DQS edges when read (edged DQ) Data inputs on DQS centers when write (centered DQ)
- Data(DQ) and Write masks(DM) latched on the both rising and falling edges of the data strobe
- All addresses and control inputs except Data, Data strobes and Data masks latched on the rising edges of the clock
- Write mask byte controls by DM (DM0 ~ DM3)
- Programmable /CAS Latency 5 / 4 / 3 supported
- Programmable Burst Length 2 / 4 / 8 with both sequential and interleave mode
- Internal 4 bank operations with single pulsed /RAS
- tRAS Lock-Out function supported
- Auto refresh and self refresh supported
- 4096 refresh cycles / 32ms
- Half strength and Matched Impedance driver option controlled by EMRS

## ORDERI NG I NFORMATI ON

| Part No. | Power Supply | Clock Frequency | Max Data Rate | interface | Package |
| :---: | :---: | :---: | :---: | :---: | :---: |
| HY5DW283222BF(P)-2 | VDd 2.5V <br> Vddo 1.8V | 500 MHz | 1000Mbps/pin | SSTL_2 | $\begin{gathered} 12 \mathrm{~mm} \times 12 \mathrm{~mm} \\ \text { 144Ball FBGA } \end{gathered}$ |
| HY5DW283222BF(P)-22 |  | 450 MHz | 900Mbps/pin |  |  |
| HY5DW283222BF(P)-25 |  | 400 MHz | 800Mbps/pin |  |  |
| HY5DW283222BF(P)-28 |  | 350 MHz | 700Mbps/pin |  |  |
| HY5DW283222BF(P)-33 |  | 300MHz | 600Mbps/pin |  |  |
| HY5DW283222BF(P)-36 |  | 275 MHz | $550 \mathrm{Mbps} / \mathrm{pin}$ |  |  |
| HY5DW283222BF(P)-4 |  | 250 MHz | 500Mbps/pin |  |  |
| HY5DW283222BF(P)-5 |  | 200MHz | 400Mbps/pin |  |  |

Note) Hynix supports Lead free parts for each speed grade with same specification, except Lead free materials. We'll add "P" character after "F" for Lead free product.

For example, the part number of 300 MHz Lead free product is HY5DW283222BFP-33.

## Note:

1. Outer ball, _A1~A14, P1~P14, A1~P1, A14~P14 are depopulated.
2. Ball $L 9(N C 2)$ is reserved for $A 12$.
3. Ball M10(NC3) is reserved for BA2.

## ROW and COLUMN ADDRESS TABLE

| Items | $\mathbf{4 M x 3 2}$ |
| :---: | :---: |
| Organization | $1 \mathrm{M} \times 32 \times 4$ banks |
| Row Address | $\mathrm{A} 0 \sim \mathrm{~A} 11$ |
| Column Address | $\mathrm{A} 0 \sim \mathrm{~A} 7$ |
| Bank Address | $\mathrm{BA} 0, \mathrm{BA} 1$ |
| Auto Precharge Flag | A 8 |
| Refresh | 4 K |

## PI N DESCRI PTI ON

| PIN | TYPE | DESCRIPTION |
| :---: | :---: | :---: |
| CK, /CK | Input | Clock: CK and /CK are differential clock inputs. All address and control input signals are sampled on the crossing of the positive edge of CK and negative edge of /CK. Output (read) data is referenced to the crossings of CK and /CK (both directions of crossing). |
| CKE | Input | Clock Enable: CKE HIGH activates, and CKE LOW deactivates internal clock signals, and device input buffers and output drivers. Taking CKE LOW provides PRECHARGE POWER DOWN and SELF REFRESH operation (all banks idle), or ACTIVE POWER DOWN (row ACTIVE in any bank). CKE is synchronous for POWER DOWN entry and exit, and for SELF REFRESH entry. CKE is asynchronous for SELF REFRESH exit, and for output disable. CKE must be maintained high throughout READ and WRITE accesses. Input buffers, excluding CK, /CK and CKE are disabled during POWER DOWN. Input buffers, excluding CKE are disabled during SELF REFRESH. CKE is an SSTL_2 input, but will detect an LVCMOS LOW level after Vdd is applied. |
| /CS | Input | Chip Select : Enables or disables all inputs except CK, /CK, CKE, DQS and DM. All commands are masked when CS is registered high. CS provides for external bank selection on systems with multiple banks. CS is considered part of the command code. |
| BA0, BA1 | Input | Bank Address Inputs: BAO and BA1 define to which bank an ACTIVE, Read, Write or PRECHARGE command is being applied. |
| A0 ~ A11 | Input | Address Inputs: Provide the row address for ACTIVE commands, and the column address and AUTO PRECHARGE bit for READ/WRITE commands, to select one location out of the memory array in the respective bank. A8 is sampled during a precharge command to determine whether the PRECHARGE applies to one bank (A8 LOW) or all banks (A8 HIGH ). If only one bank is to be precharged, the bank is selected by BAO, BA1. The address inputs also provide the op code during a MODE REGISTER SET command. BAO and BA1 define which mode register is loaded during the MODE REGISTER SET command (MRS or EMRS). |
| /RAS, /CAS, /WE | Input | Command Inputs: /RAS, /CAS and /WE (along with /CS) define the command being entered. |
| DM0 ~ DM3 | Input | Input Data Mask: $\mathrm{DM}(0 \sim 3)$ is an input mask signal for write data. Input data is masked when DM is sampled HIGH along with that input data during a WRITE access. DM is sampled on both edges of DQS. Although DM pins are input only, the DM loading matches the DQ and DQS loading. DM0 corresponds to the data on DQ0-Q7; DM1 corresponds to the data on DQ8-Q15; DM2 corresponds to the data on DQ16-Q23; DM3 corresponds to the data on DQ24-Q31. |
| DQS0 ~ DQS3 | 1/0 | Data Strobe: Output with read data, input with write data. Edge aligned with read data, centered in write data. Used to capture write data. DQS0 corresponds to the data on DQ0-Q7; DQS1 corresponds to the data on DQ8-Q15; DQS2 corresponds to the data on DQ16-Q23; DQS3 corresponds to the data on DQ24-Q31 |
| DQ0 ~ DQ31 | 1/0 | Data input / output pin : Data Bus |
| VDD/VSS | Supply | Power supply for internal circuits and input buffers. |
| VDDQ/VSSQ | Supply | Power supply for output buffers for noise immunity. |
| VREF | Supply | Reference voltage for inputs for SSTL interface. |
| NC | NC | No connection. |

( H=Logic High Level, L=Logic Low Level, X=Don't Care, V=Valid Data Input, OP Code=Operand Code, NOP=No Operation )

## Note :

1. $\mathrm{DM}(0 \sim 3)$ states are Don't Care. Refer to below Write Mask Truth Table.
2. OP Code(Operand Code) consists of A0~A11 and BA0~BA1 used for Mode Register setting during Extended MRS or MRS. Before entering Mode Register Set mode, all banks must be in a precharge state and MRS command can be issued after tRP period from Prechagre command.
3. If a Read with Autoprecharge command is detected by memory component in $\mathrm{CK}(\mathrm{n})$, then there will be no command presented to activated bank until CK ( $n+B L / 2+t R P)$.
4. If a Write with Autoprecharge command is detected by memory component in $\mathrm{CK}(\mathrm{n})$, then there will be no command presented to activated bank until CK( $n+B L / 2+1+t D P L+t R P)$. Last Data-In to Prechage delay(tDPL) which is also called Write Recovery Time (tWR) is needed to guarantee that the last data has been completely written.
5. If A8/AP is High when Precharge command being issued, BA0/BA1 are ignored and all banks are selected to be precharged.

HY5DW283222BF(P)

## WRITE MASK TRUTH TABLE

| Function | CKEn-1 | CKEn | /CS, / RAS, <br> /CAS, / WE | DM(0~3) | ADDR | A8/ <br> AP | BA | Note |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Note:

1. H - Logic High Level, L - Logic Low Level, X - Don't Care, V - Valid Data Input,

BA - Bank Address, AP - AutoPrecharge Address, CA - Column Address, RA - Row Address, NOP - NO Operation.
2. All entries assume that CKE was active(high level) during the preceding clock cycle.
3. If both banks are idle and CKE is inactive(low level), then in power down mode.
4. Illegal to bank in specified state. Function may be legal in the bank indicated by Bank Address(BA) depending on the state of that bank.
5. If both banks are idle and CKE is inactive(low level), then self refresh mode.
6. Illegal if $t R C D$ is not met.
7. Illegal if tRAS is not met.
8. Must satisfy bus contention, bus turn around, and/or write recovery requirements.
9. Illegal if tRRD is not met.
10. Illegal for single bank, but legal for other banks in multi-bank devices.
11. Illegal for all banks.

HY5DW283222BF(P)

## Note :

When $\mathrm{CKE}=\mathrm{L}$, all DQ and $\mathrm{DQS}(0 \sim 3)$ must be in Hi-Z state.

1. CKE and /CS must be kept high for a minimum of 200 stable input clocks before issuing any command.
2. All command can be stored after 2 clocks from low to high transition of CKE.
3. Illegal if CK is suspended or stopped during the power down mode.
4. Self refresh can be entered only from the all banks idle state.
5. Disabling CK may cause malfunction of any bank which is in active state.

## SI MPLI FI ED STATE DI AGRAM

## POWER-UP SEQUENCE AND DEVI CE I NI TI ALI ZATI ON

DDR SDRAMs must be powered up and initialized in a predefined manner. Operational procedures other than those specified may result in undefined operation. Except for CKE, inputs are not recognized as valid until after VREF is applied. CKE is an SSTL_2 input, but will detect an LVCMOS LOW level after VDD is applied. Maintaining an LVCMOS LOW level on CKE during power-up is required to guarantee that the DQ and DQS outputs will be in the High-Z state, where they will remain until driven in normal operation (by a read access). After all power supply and reference voltages are stable, and the clock is stable, the DDR SDRAM requires a 200 us delay prior to applying an executable command.

Once the 200us delay has been satisfied, a DESELECT or NOP command should be applied, and CKE should be brought HIGH. Following the NOP command, a PRECHARGE ALL command should be applied. Next a EXTENDED MODE REGISTER SET command should be issued for the Extended Mode Register, to enable the DLL, then a MODE REGISTER SET command should be issued for the Mode Register, to reset the DLL, and to program the operating parameters. After the DLL reset, tXSRD(DLL locking time) should be satisfied for read command. After the Mode Register set command, a PRECHARGE ALL command should be applied, placing the device in the all banks idle state.

Once in the idle state, two AUTO REFRESH cycles must be performed. Additionally, a MODE REGISTER SET command for the Mode Register, with the reset DLL bit deactivated (i.e. to program operating parameters without resetting the DLL) must be performed. Following these cycles, the DDR SDRAM is ready for normal operation.

1. Apply power - VDD, VDDQ, VTT, VREF in the following power up sequencing and attempt to maintain CKE at LVCMOS low state. (All the other input pins may be undefined.

No power sequencing is specified during power up or power down given the following cirteria :

- VDD and VDDQ are driven from a single power converter output.
- VTT is limited to 1.44 V (reflecting VDDQ $(\max ) / 2+50 \mathrm{mV}$ VREF variation +40 mV VTT variation).
- VREF tracks VDDQ/2.
- A minimum resistance of 42 ohms ( 22 ohm series resistor +22 ohm parallel resistor $-5 \%$ tolerance) limits the input current from the VTT supply into any pin.

If the above criteria cannot be met by the system design, then the following sequencing and voltage relationship must be adhered to during power up :

| Voltage description | Sequencing | Voltage relationship to avoid latch-up |
| :---: | :---: | :---: |
| VDDQ | After or with VDD | $<$ VDD +0.3 V |
| VTT | After or with VDDQ | $<$ VDDQ +0.3 V |
| VREF | After or with VDDQ | $<$ VDDQ +0.3 V |

2. Start clock and maintain stable clock for a minimum of 200 usec.
3. After stable power and clock, apply NOP condition and take CKE high.
4. Issue Extended Mode Register Set (EMRS) to enable DLL.
5. Issue Mode Register Set (MRS) to reset DLL and set device to idle state with bit A8=high. (An additional 200 cycles of clock are required for locking DLL)
6. Issue Precharge commands for all banks of the device.
7. Issue 2 or more Auto Refresh commands.
8. Issue a Mode Register Set command to initialize the mode register with bit A8 = Low.

## ициіх

## Power-Up Sequence

## MODE REGI STER SET (MRS)

The mode register is used to store the various operating modes such as /CAS latency, addressing mode, burst length, burst type, test mode, DLL reset. The mode register is program via MRS command. This command is issued by the low signals of /RAS, /CAS, /CS, /WE and BAO. This command can be issued only when all banks are in idle state and CKE must be high at least one cycle before the Mode Register Set Command can be issued. Two cycles are required to write the data in mode register. During the the MRS cycle, any command cannot be issued. Once mode register field is determined, the information will be held until resetted by another MRS command.

## BURST LENGTH \& TYPE

Read and write accesses to the DDR SDRAM are burst oriented, with the burst length being programmable. The burst length determines the maximum number of column locations that can be accessed for a given Read or Write command. Burst lengths of 2,4 or 8 locations are available for both the sequential and the interleaved burst types. Reserved states should not be used, as unknown operation or incompatibility with future versions may result.
When a Read or Write command is issued, a block of columns equal to the burst length is effectively selected. All accesses for that burst take place within this block, meaning that the burst wraps within the block if a boundary is reached. The block is uniquely selected by A1-Ai when the burst length is set to two, by A2-Ai when the burst length is set to four and by A3-Ai when the burst length is set to eight (where Ai is the most significant column address bit for a given configuration). The remaining (least significant) address bit(s) is (are) used to select the starting location within the block. The programmed burst length applies to both Read and Write bursts.
Accesses within a given burst may be programmed to be either sequential or interleaved; this is referred to as the burst type and is selected via bit A3. The ordering of accesses within a burst is determined by the burst length, the burst type and the starting column address, as shown in Burst Definitionon Table

## CAS LATENCY

The Read latency or CAS latency is the delay in clock cycles between the registration of a Read command and the availability of the first burst of output data. The latency can be programmed 5 / 4 / 3 clocks

If a Read command is registered at clock edge $n$, and the latency is $m$ clocks, the data is available nominally coincident with clock edge $n+m$.

Reserved states should not be used as unknown operation or incompatibility with future versions may result.

## DLL RESET

The DLL must be enabled for normal operation. DLL enable is required during power up initialization, and upon returning to normal operation after having disabled the DLL for the purpose of debug or evaluation. The DLL is automatically disabled when entering self refresh operation and is automatically re-enabled upon exit of self refresh operation. Any time the DLL is enabled, 200 clock cycles must occur to allow time for the internal clock to lock to the externally applied clock before an any command can be issued.

## OUTPUT DRI VER IMPEDANCE CONTROL

This device supports both Half strength driver and Matched impedance driver, intended for lighter load and/or point-topoint environments. Half strength driver is to define about $50 \%$ of Full drive strength which is specified to be SSTL_2, Class II, and Matched impedance driver, about 30\% of Full drive strength.

## EXTENDED MODE REGI STER SET (EMRS)

The Extended Mode Register controls functions beyond those controlled by the Mode Register; these additional functions include DLL enable/disable, output driver strength selection(optional). These functions are controlled via the bits shown below. The Extended Mode Register is programmed via the Mode Register Set command ( $\mathrm{BA} 0=1$ and $\mathrm{BA} 1=0$ ) and will retain the stored information until it is programmed again or the device loses power.

The Extended Mode Register must be loaded when all banks are idle and no bursts are in progress, and the controller must wait the specified time before initiating any subsequent operation. Violating either of these requirements will result in unspecified operation.

## Note:

1. This calculation accounts for tDQSQ(max), the pulse width distortion of on-chip circuit and jitter.
2. Data sampled at the rising edges of the clock: A0~A11, BA0~BA1, CKE, /CS, /RAS, /CAS, /WE.
3. Data latched at both rising and falling edges of Data Strobes(DQS0~DQS3) : DQ, DM(0~3).
4. Minimum of 200 cycles of stable input clocks after Self Refresh Exit command, where CKE is held high, is required to complete Self Refresh Exit and lock the internal DLL circuit of DDR SDRAM.
5. Min ( $\mathrm{tCL}, \mathrm{tCH}$ ) refers to the smaller of the actual clock low time and the actual clock high time as provided to the device (i.e. this value can be greater than the minimum specification limits for tCL and tCH).
6. $\mathrm{tHP}=$ minimum half clock period for any given cycle and is defined by clock high or clock low ( $\mathrm{tCH}, \mathrm{tCL}$ ). tQHS consists of tDQSQmax, the pulse width distortion of on-chip clock circuits, data pin to pin skew and output pattern effects, and $p$-channel to $n$-channel variation of the output drivers.
7. DQS, DM and DQ input slew rate is specified to prevent double clocking of data and preserve setup and hold times. Signal transitions through the DC region must be monotonic.
