*Data Sheet (Retired Product)*

---

This product has been retired and is not recommended for new designs. Availability of this document is retained for reference and historical purposes only.

## **Continuity of Specifications**

There is no change to this data sheet as a result of offering the device as a Spansion product. Any changes that have been made are the result of normal data sheet improvement and are noted in the document revision summary.

## **For More Information**

Please contact your local sales office for additional information about Spansion memory solutions.

**This page left intentionally blank.**

# SPANSION™ Flash Memory

Data Sheet

September 2003

This document specifies SPANSION™ memory products that are now offered by both Advanced Micro Devices and Fujitsu. Although the document is marked with the name of the company that originally developed the specification, these products will be offered to customers of both AMD and Fujitsu.

## Continuity of Specifications

There is no change to this datasheet as a result of offering the device as a SPANSION™ product. Future routine revisions will occur when appropriate, and changes will be noted in a revision summary.

## Continuity of Ordering Part Numbers

AMD and Fujitsu continue to support existing part numbers beginning with "Am" and "MBM". To order these products, please use only the Ordering Part Numbers listed in this document.

## For More Information

Please contact your local AMD or Fujitsu sales office for additional information about SPANSION™ memory solutions.

# FLASH MEMORY

CMOS

## 32 M (4 M × 8/2 M × 16) BIT

### MBM29LV320TE 80/90/10

### MBM29LV320BE 80/90/10

#### DESCRIPTION

The MBM29LV320TE/BE is 32 M-bit, 3.0 V-only Flash memory organized as 4 M bytes of 8 bits each or 2 M words of 16 bits each. The device is offered in a 48-pin TSOP (1) and 63-ball FBGA packages. This device is designed to be programmed in-system with the standard system 3.0 V  $V_{CC}$  supply. 12.0 V  $V_{PP}$  and 5.0 V  $V_{CC}$  are not required for write or erase operations. The device can also be reprogrammed in standard EPROM programmers.

The standard device offers access times 80 ns, 90 ns and 100 ns, allowing operation of high-speed microprocessors without wait state. To eliminate bus contention the device has separate chip enable ( $\overline{CE}$ ), write enable ( $\overline{WE}$ ) and output enable ( $\overline{OE}$ ) controls.

(Continued)

#### PRODUCT LINE UP

Part No.	MBM29LV320TE/BE		
	80	90	100
Power Supply Voltage (V)	$V_{CC} = 3.3 V_{-0.3V}^{+0.3V}$		$V_{CC} = 3.0 V_{-0.3V}^{+0.6V}$
Max Address Access Time (ns)	80	90	100
Max $\overline{CE}$ Access Time (ns)	80	90	100
Max $\overline{OE}$ Access Time (ns)	30	35	35

#### PACKAGES

(Continued)

The device is pin and command set compatible with JEDEC standard E<sup>2</sup>PROMs. Commands are written to the command register using standard microprocessor write timings. Register contents serve as input to an internal state-machine which controls the erase and programming circuitry. Write cycles also internally latch addresses and data needed for the programming and erase operations. Reading data out of the device is similar to reading from 5.0 V and 12.0 V Flash or EPROM devices.

The device is programmed by executing the program command sequence. This invokes the Embedded Program Algorithm which is an internal algorithm that automatically times the program pulse widths and verifies proper cell margin. Typically, each sector can be programmed and verified in about 0.5 seconds. Erase is accomplished by executing the erase command sequence. This invokes the Embedded Erase Algorithm which is an internal algorithm that automatically preprograms the array if it is not already programmed before executing the erase operation. During erase, the device automatically time the erase pulse widths and verify proper cell margin.

A sector is Typically erased and verified in 1.0 second. (If already completely preprogrammed.)

The device also features a sector erase architecture. The sector mode allows each sector to be erased and reprogrammed without affecting other sectors. The device is erased when shipped from the factory.

The device features single 3.0 V power supply operation for both read and write functions. Internally generated and regulated voltages are provided for the program and erase operations. A low V<sub>CC</sub> detector automatically inhibits write operations on the loss of power. The end of program or erase is detected by  $\overline{\text{Data}}$  Polling of DQ<sub>7</sub>, by the Toggle Bit feature on DQ<sub>6</sub>, or the RY/ $\overline{\text{BY}}$  output pin. Once the end of a program or erase cycle is completed, the device internally resets to the read mode.

The device also has a hardware  $\overline{\text{RESET}}$  pin. When this pin is driven low, execution of any Embedded Program Algorithm or Embedded Erase Algorithm is terminated. The internal state machine is then reset to the read mode. The  $\overline{\text{RESET}}$  pin may be tied to the system reset circuitry. Therefore, if a system reset occurs during the Embedded Program Algorithm or Embedded Erase Algorithm, the device is automatically reset to the read mode and will have erroneous data stored in the address locations being programmed or erased. These locations need re-writing after the reset. Resetting the device enables the system's microprocessor to read the boot-up firmware from the Flash memory.

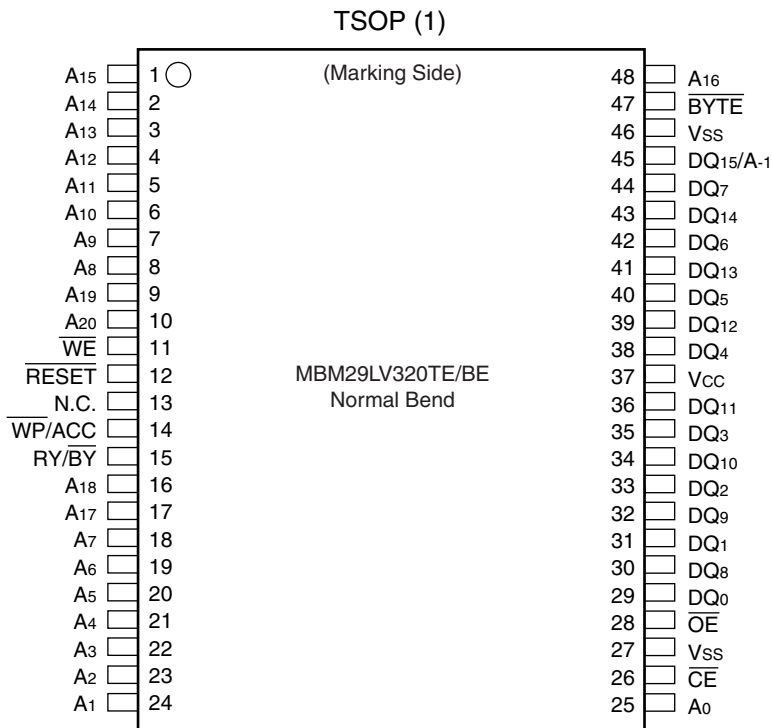

Fujitsu Flash technology combines years of EPROM and E<sup>2</sup>PROM experience to produce the highest levels of quality, reliability, and cost effectiveness. The device memory electrically erase the entire chip or all bits within a sector simultaneously via Fowler-Nordhiem tunneling. The bytes/words are programmed one byte/word at a time using the EPROM programming mechanism of hot electron injection.

## ■ FEATURES

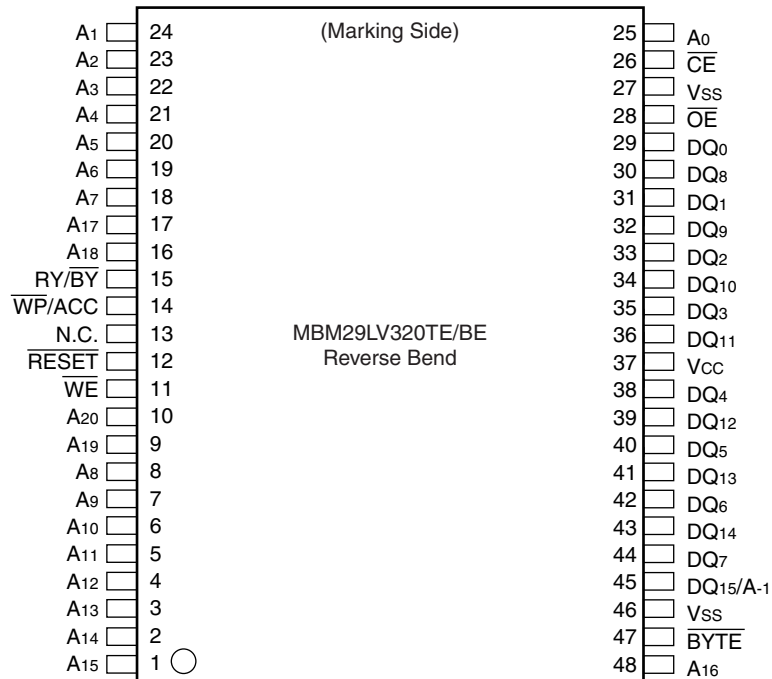

- **0.23  $\mu$ m Process Technology**
- **Single 3.0 V Read, Program, and Erase**  
Minimized system level power requirements
- **Compatible with JEDEC-standard Commands**  
Use the same software commands as E<sup>2</sup>PROMs
- **Compatible with JEDEC-standard Worldwide Pinouts**  
48-pin TSOP (1) (Package suffix : TN – Normal Bend Type, TR – Reversed Bend Type)  
63-ball FBGA (Package suffix : PBT)
- **Minimum 100,000 Program/Erase Cycles**
- **High Performance**  
80 ns maximum access time
- **Sector Erase Architecture**  
Eight 4 K word and sixty-three 32 K word sectors in word mode  
Eight 8 K byte and sixty-three 64 K byte sectors in byte mode  
Any combination of sectors can be concurrently erased. Also supports full chip erase.
- **Boot Code Sector Architecture**  
T = Top sector  
B = Bottom sector
- **HiddenROM Region**  
256 byte of HiddenROM, accessible through a new “HiddenROM Enable” command sequence  
Factory serialized and protected to provide a secure electronic serial number (ESN)
- **WP/ACC Input Pin**  
At V<sub>IL</sub>, allows protection of boot sectors, regardless of sector protection/unprotection status  
At V<sub>ACC</sub>, increases program performance
- **Embedded Erase™\* Algorithms**  
Automatically pre-programs and erases the chip or any sector
- **Embedded Program™\* Algorithms**  
Automatically writes and verifies data at specified address
- **Data Polling and Toggle Bit feature for detection of program or erase cycle completion**
- **Ready/Busy output (RY/BY)**  
Hardware method for detection of program or erase cycle completion
- **Automatic sleep mode**  
When addresses remain stable, automatically switch themselves to low power mode.
- **Low V<sub>CC</sub> write inhibit  $\leq$  2.5 V**
- **Erase Suspend/Resume**  
Suspends the erase operation to allow a read data and/or program in another sector within the same device
- **Sector group protection**  
Hardware method disables any combination of sector groups from program or erase operations
- **Sector Group Protection Set function by Extended sector group protection command**
- **Fast Programming Function by Extended Command**
- **Temporary sector group unprotection**  
Temporary sector group unprotection via the  $\overline{\text{RESET}}$  pin.
- **In accordance with CFI (Common Flash Memory Interface)**

(Continued)

# MBM29LV320TE/BE<sub>80/90/10</sub>

(Continued)

- \*1 : This command is valid during Fast Mode.
- \*2 : This command is valid while  $\overline{\text{RESET}} = V_{\text{ID}}$ .
- \*3 : The valid addresses are A<sub>6</sub> to A<sub>0</sub>.
- \*4 : This command is valid during HiddenROM mode (except during HiddenROM mode).
- \*5 : The data "00h" is also acceptable.
- \*6 : Both of these reset commands are equivalent.
- \*7 : The fourth bus cycle is only for read.

- Notes:
- Address bits A<sub>20</sub> to A<sub>11</sub> = X = "H" or "L" for all address commands except or Program Address (PA) and Sector Address (SA) .
  - Bus operations are defined in "MBM29LV320TE/BE User Bus Operations Tables ( $\overline{\text{BYTE}} = V_{\text{IH}}$  and  $\overline{\text{BYTE}} = V_{\text{IL}}$ )" .
  - RA = Address of the memory location to be read  
 IA = Autoselect read address that sets both the bank address specified at (A<sub>19</sub>, A<sub>18</sub>, A<sub>17</sub>, A<sub>16</sub>, A<sub>15</sub>) and all the other A<sub>6</sub>, A<sub>1</sub>, A<sub>0</sub>, (A-1) .  
 PA = Address of the memory location to be programmed  
 Addresses are latched on the falling edge of the write pulse.  
 SA = Address of the sector to be erased. The combination of A<sub>20</sub>, A<sub>19</sub>, A<sub>18</sub>, A<sub>17</sub>, A<sub>16</sub>, A<sub>15</sub>, A<sub>14</sub>, A<sub>13</sub>, and A<sub>12</sub> will uniquely select any sector.
  - RD = Data read from location RA during read operation.  
 ID = Device code/manufacture code for the address located by IA.  
 PD = Data to be programmed at location PA. Data is latched on the rising edge of write pulse.
  - SPA = Sector group address to be protected. Set sector group address (SGA) and (A<sub>6</sub>, A<sub>1</sub>, A<sub>0</sub>) = (0, 1, 0).  
 SD = Sector group protection verify data. Output 01h at protected sector group addresses and output 00h at unprotected sector group addresses.
  - HRA = Address of the HiddenROM area
 

29LV320TE (Top Boot Type)	Word Mode :	1FFFE0h to 1FFFFFFh
	Byte Mode :	3FFFC0h to 3FFFFFFh
29LV320BE (Bottom Boot Type)	Word Mode :	000000h to 000040h
	Byte Mode :	000000h to 000080h
  - The system should generate the following address patterns :  
 Word Mode : 555h or 2AAh to addresses A<sub>10</sub> to A<sub>0</sub>  
 Byte Mode : AAh or 55h to addresses A<sub>10</sub> to A<sub>0</sub>, and A-1
  - Both Read/Reset commands are functionally equivalent, resetting the device to the read mode.
  - The command combinations not described in "MBM29LV320TE/BE Command Definition Table" are illegal.

## ■ FUNCTIONAL DESCRIPTION

### 1. Read Mode

The device has two control functions which must be satisfied in order to obtain data at the outputs.  $\overline{CE}$  is the power control and should be used for a device selection.  $\overline{OE}$  is the output control and used to gate data to the output pins if a device is selected.

Address access time ( $t_{ACC}$ ) is equal to the delay from stable addresses to valid output data. The chip enable access time ( $t_{CE}$ ) is the delay from stable addresses and stable  $\overline{CE}$  to valid data at the output pins. The output enable access time is the delay from the falling edge of  $\overline{OE}$  to valid data at the output pins. Assuming the addresses have been stable for at least  $t_{ACC-tOE}$  time. When reading out data without changing addresses after power-up, input hardware reset or to change  $\overline{CE}$  pin from “H” or “L”.

### 2. Standby Mode

There are two ways to implement the standby mode on the device, one using both the  $\overline{CE}$  and  $\overline{RESET}$  pins; the other via the  $\overline{RESET}$  pin only.

When using both pins, CMOS standby mode is achieved with  $\overline{CE}$  and  $\overline{RESET}$  inputs both held at  $V_{CC} \pm 0.3 V$ . Under this condition the current consumed is less than 5  $\mu A$  Max During Embedded Algorithm operation,  $V_{CC}$  active current ( $I_{CC2}$ ) is required even when  $\overline{CE} = \text{“H”}$ . The device can be read with standard access time ( $t_{CE}$ ) from either of these standby modes.

When using the  $\overline{RESET}$  pin only, CMOS standby mode is achieved with  $\overline{RESET}$  input held at  $V_{SS} \pm 0.3 V$  ( $\overline{CE} = \text{“H”}$  or “L”). Under this condition the current consumed is less than 5  $\mu A$  Max Once the  $\overline{RESET}$  pin is taken high, the device requires  $t_{RH}$  as wake up time for outputs to be valid for read access.

In the standby mode the outputs are in the high impedance state independently of the  $\overline{OE}$  input.

### 3. Automatic Sleep Mode

There is a function called automatic sleep mode to restrain power consumption during read-out of the device data. This mode can be useful in the application such as a handy terminal which requires low power consumption.

To activate this mode, the device automatically switches themselves to low power mode when the device addresses remain stable during access time of 150 ns. It is not necessary to control  $\overline{CE}$ ,  $\overline{WE}$ , and  $\overline{OE}$  on the mode. Under the mode, the current consumed is typically 1  $\mu A$  (CMOS Level).

During simultaneous operation,  $V_{CC}$  active current ( $I_{CC2}$ ) is required.

Since the data are latched during this mode, the data are read-out continuously. If the addresses are changed, the mode is canceled automatically, and the device read the data for changed addresses.

### 4. Output Disable

With the  $\overline{OE}$  input at logic high level ( $V_{IH}$ ), output from the device is disabled. This will causes the output pins to be in a high impedance state.

### 5. Autoselect

Autoselect mode allows reading out of a binary code from the device and will identify its manufacturer and type. This mode is intended for use by programming equipment for the purpose of automatically matching the device to be programmed with its corresponding programming algorithm. This mode is functional over the entire temperature range of the device.

To activate this mode, the programming equipment must force  $V_{ID}$  (11.5 V to 12.5 V) on address pin  $A_9$ . Two identifier bytes may then be sequenced from the device outputs by toggling address  $A_0$  from  $V_{IL}$  to  $V_{IH}$ . All addresses are DON'T CARES except  $A_6$ ,  $A_1$ , and  $A_0$  ( $A_{-1}$ ). (See “MBM29LV320TE/BE User Bus Operations Tables ( $\overline{BYTE} = V_{IH}$  and  $\overline{BYTE} = V_{IL}$ )” in ■DEVICE BUS OPERATIONS.)

The manufacturer and device codes may also be read via the command register, for instances when the device is erased or programmed in a system without access to high voltage on the  $A_9$  pin. The command sequence is illustrated in “MBM29LV320TE/BE Command Definitions Table” (■DEVICE BUS OPERATIONS) (See “2. Autoselect Command” in ■COMAND DIFINITIONS).

Word 0 ( $A_0 = V_{IL}$ ) represents the manufacturer's code (Fujitsu = 04h) and word 1 ( $A_0 = V_{IH}$ ) represents the device identifier code. Word 3 ( $A_1 = A_0 = V_{IH}$ ) represents the extended device code. These three bytes/words are given in "MBM29LV320TE/BE Sector Group Protection Verify Autoselect Codes Table" and "Extended Autoselect Code Table" (■DEVICE BUS OPERATIONS). In order to read the proper device codes when executing the autoselect,  $A_1$  must be  $V_{IL}$ . (See "MBM29LV320TE/BE Sector Group Protection Verify Autoselect Codes Table" and "Extended Autoselect Code Table" in ■DEVICE BUS OPERATIONS.)

## 6. Write

The device erasure and programming are accomplished via the command register. The contents of the register serve as inputs to the internal state machine. The state machine outputs dictate the device function.

The command register itself does not occupy any addressable memory location. The register is a latch used to store the commands, along with the address and data information needed to execute the command. The command register is written by bringing  $\overline{WE}$  to  $V_{IL}$ , while  $\overline{CE}$  is at  $V_{IL}$  and  $\overline{OE}$  is at  $V_{IH}$ . Addresses are latched on the falling edge of  $\overline{WE}$  or  $\overline{CE}$ , whichever starts later; while data is latched on the rising edge of  $\overline{WE}$  or  $\overline{CE}$ , whichever starts first. Standard microprocessor write timings are used.

See "Read Only Operation Characteristics" in ■AC CHARACTERISTICS for specific timing parameters.

## 7. Sector Group Protection

The device features hardware sector group protection. This feature disables both program and erase operations in any combination of twenty five sector groups of memory. See "Sector Group Address Tables (MBM29LV320TE/BE)" in ■FLEXIBLE SECTOR-ERASE ARCHITECTURE. The sector group protection feature is enabled using programming equipment at the user's site. The device is shipped with all sector groups unprotected.

To activate it, the programming equipment must force  $V_{ID}$  on address pin  $A_9$  and control pin  $\overline{OE}$ , (suggest  $V_{ID} = 11.5\text{ V}$ ),  $\overline{CE} = V_{IL}$  and  $A_6 = A_0 = V_{IL}$ ,  $A_1 = V_{IH}$ . The sector group addresses ( $A_{20}$ ,  $A_{19}$ ,  $A_{18}$ ,  $A_{17}$ ,  $A_{16}$ ,  $A_{15}$ ,  $A_{14}$ ,  $A_{13}$ , and  $A_{12}$ ) should be set to the sector to be protected. "Sector Address Tables (MBM29LV320TE/BE)" in ■FLEXIBLE SECTOR-ERASE ARCHITECTURE define the sector address for each of the seventy one (71) individual sectors, and "Sector Group Address Tables (MBM29LV320TE/BE)" in ■FLEXIBLE SECTOR-ERASE ARCHITECTURE define the sector group address for each of the twenty five (25) individual group sectors. Programming of the protection circuitry begins on the falling edge of the  $\overline{WE}$  pulse and is terminated with the rising edge of the same. Sector group addresses must be held constant during the  $\overline{WE}$  pulse. See "14. Sector Group Protection Timing Diagram" in ■TIMING DIAGRAM and "5. Sector Group Protection Algorithm" in ■FLOW CHART for sector group protection waveforms and algorithm.

To verify programming of the protection circuitry, the programming equipment must force  $V_{ID}$  on address pin  $A_9$  with  $\overline{CE}$  and  $\overline{OE}$  at  $V_{IL}$  and  $\overline{WE}$  at  $V_{IH}$ . Scanning the sector group addresses ( $A_{20}$ ,  $A_{19}$ ,  $A_{18}$ ,  $A_{17}$ ,  $A_{16}$ ,  $A_{15}$ ,  $A_{14}$ ,  $A_{13}$ , and  $A_{12}$ ) while  $(A_6, A_1, A_0) = (0, 1, 0)$  produces a logic "1" code at device output  $DQ_0$  for a protected sector. Otherwise the device produces "0" for unprotected sector. In this mode, the lower order addresses, except for  $A_0$ ,  $A_1$ , and  $A_6$  are DON'T CARES. Address locations with  $A_1 = V_{IL}$  are reserved for Autoselect manufacturer and device codes.  $A_{-1}$  requires to apply  $V_{IL}$  on byte mode.

It is also possible to determine if a sector group is protected in the system by writing an Autoselect command. Performing a read operation at the address location XX02h, where the higher order addresses ( $A_{20}$ ,  $A_{19}$ ,  $A_{18}$ ,  $A_{17}$ ,  $A_{16}$ ,  $A_{15}$ ,  $A_{14}$ ,  $A_{13}$ , and  $A_{12}$ ) are the desired sector group address will produce a logical "1" at  $DQ_0$  for a protected sector group. See "MBM29LV320TE/BE Sector Group Protection Verify Autoselect Codes Table" and "Extended Autoselect Code Table" in ■DEVICE BUS OPERATIONS for Autoselect codes.

## 8. Temporary Sector Group Unprotection

This feature allows temporary unprotection of previously protected sector groups of the device in order to change data. The Sector Group Unprotection mode is activated by setting the  $\overline{RESET}$  pin to high voltage ( $V_{ID}$ ). During this mode, formerly protected sector groups can be programmed or erased by selecting the sector group addresses. Once the  $V_{ID}$  is taken away from the  $\overline{RESET}$  pin, all the previously protected sector groups will be protected again. See "15. Temporary Sector Group Unprotection Timing Diagram" in ■TIMING DIAGRAM and "6. Temporary Sector Group Unprotection Algorithm" in ■FLOW CHART.

## 9. Extended Sector Group Protection

In addition to normal sector group protection, the device has Extended Sector Group Protection as extended function. This function enables to protect sector group by forcing  $V_{ID}$  on  $\overline{RESET}$  pin and write a command sequence. Unlike conventional procedure, it is not necessary to force  $V_{ID}$  and control timing for control pins. The extended sector group protection requires  $V_{ID}$  on  $\overline{RESET}$  pin only. With this condition, the operation is initiated by writing the set-up command (60h) into the command register. Then, the sector group addresses pins ( $A_{20}$ ,  $A_{19}$ ,  $A_{18}$ ,  $A_{17}$ ,  $A_{16}$ ,  $A_{15}$ ,  $A_{14}$ ,  $A_{13}$  and  $A_{12}$ ) and ( $A_6$ ,  $A_1$ ,  $A_0$ ) = (0, 1, 0) should be set to the sector group to be protected (recommend to set  $V_{IL}$  for the other addresses pins), and write extended sector group protection command (60h). A sector group is typically protected in 250  $\mu$ s. To verify programming of the protection circuitry, the sector group addresses pins ( $A_{20}$ ,  $A_{19}$ ,  $A_{18}$ ,  $A_{17}$ ,  $A_{16}$ ,  $A_{15}$ ,  $A_{14}$ ,  $A_{13}$  and  $A_{12}$ ) and ( $A_6$ ,  $A_1$ ,  $A_0$ ) = (0, 1, 0) should be set and write a command (40h). Following the command write, a logic "1" at device output  $DQ_0$  will produce for protected sector in the read operation. If the output is logic "0", please repeat to write extended sector group protection command (60h) again. To terminate the operation, it is necessary to set  $\overline{RESET}$  pin to  $V_{IH}$ . (See "16. Extended Sector Group Protection Timing Diagram" in ■TIMING DIAGRAM and "7. Extended Sector Group Protection Algorithm" in ■FLOW CHART.)

## 10. $\overline{RESET}$

### Hardware Reset

The device resets by driving  $\overline{RESET}$  pin to  $V_{IL}$ . The  $\overline{RESET}$  pin has pulse requirement and has to be kept low ( $V_{IL}$ ) for at least " $t_{RP}$ " in order to properly reset internal state machine. Any operation in the process of being executed is terminated and the internal state machine is reset to the read mode " $t_{READY}$ " after the  $\overline{RESET}$  pin is driven low. Furthermore once the  $\overline{RESET}$  pin goes high, the device requires an additional " $t_{RH}$ " before it allows read access. When the  $\overline{RESET}$  pin is low, the device is in the standby mode for the duration of the pulse and all the data output pins are tri-stated. If a hardware reset occurs during program or erase operation, the data at that particular location will be corrupted. Please note that the  $\overline{RY/BY}$  output signal should be ignored during the  $\overline{RESET}$  pulse. See "10.  $\overline{RESET}$ ,  $\overline{RY/BY}$  Timing Diagram" in ■TIMING DIAGRAM for the timing diagram. See "8. Temporary Sector Group Unprotection" for additional functionality.

## 11. Boot Block Sector Protection

The Write Protection function provides hardware method of protecting certain boot sectors without using  $V_{ID}$ . This function is provided by the  $\overline{WP/ACC}$  pin.

If the system asserts  $V_{IL}$  on the  $\overline{WP/ACC}$  pin, the device disables program and erase functions in the two "outermost" 8 K byte boot sectors (MBM29LV320TE : SA69 and SA70, MBM29LV320BE : SA0 and SA1) independently of whether those sectors are protected or unprotected using the method described in "Sector Group Protection". The two outermost 8 K byte boot sectors are the two sectors containing the lowest addresses in a bottom-boot-configured device, or the two sectors containing the highest addresses in a top-boot-configured device.

If the system asserts  $V_{IH}$  on the  $\overline{WP/ACC}$  pin, the device reverts to whether the two outermost 8 K byte boot sectors were last set to be protected or unprotected. That is, sector group protection or unprotection for these two sectors depends on whether they were last protected or unprotected using the method described in "Sector Group Protection".

## 12. Accelerated Program Operation

The device offers accelerated program operation which enables the programming in high speed. If the system asserts  $V_{ACC}$  to the  $\overline{WP/ACC}$  pin, the device automatically enters the acceleration mode and the time required for program operation will reduce to about 60%. This function is primarily intended to allow high speed program, so caution is needed as the sector group becomes temporarily unprotected.

The system uses fast program command sequence when programming during acceleration mode. Set command to fast mode and reset command from fast mode are not necessary. When the device enters the acceleration mode, the device automatically set to fast mode. Therefore the present sequence is used for programming and detection of completion during acceleration mode.

Removing  $V_{ACC}$  from the  $\overline{WP/ACC}$  pin returns the device to normal operation. Do not remove  $V_{ACC}$  from  $\overline{WP/ACC}$  pin while programming. See "17. Accelerated Program Timing Diagram" in ■TIMING DIAGRAM.

Erase operation during Accelerated Program Operation is strictly prohibited.

## ■ COMMAND DEFINITIONS

The device operations are selected by writing specific address and data sequences into the command register. Writing incorrect address and data values or writing them in the improper sequence will reset the device to the read mode. “MBM29LV320TE/BE Command Definitions Table” in ■DEVICE BUS OPERATIONS defines the valid register command sequences. Note that the Erase Suspend (B0h) and Erase Resume (30h) commands are valid only while the Sector Erase operation is in progress. Moreover both Read/Reset commands are functionally equivalent, resetting the device to the read mode. Please note that commands are always written at DQ<sub>7</sub> to DQ<sub>0</sub> and DQ<sub>15</sub> to DQ<sub>8</sub> bits are ignored.

### 1. Read/Reset Command

In order to return from Autoselect mode or Exceeded Timing Limits (DQ<sub>5</sub> = 1) to Read/Reset mode, the Read/Reset operation is initiated by writing the Read/Reset command sequence into the command register. Microprocessor read cycles retrieve array data from the memory. The device remain enabled for reads until the command register contents are altered.

The device automatically powers up in the Read/Reset state. In this case, a command sequence is not required to read data. Standard microprocessor read cycles retrieves array data. This default value ensures that no spurious alteration of the memory content occurs during the power transition. See “■AC CHARACTERISTICS” for the specific timing parameters.

### 2. Autoselect Command

Flash memories are intended for use in applications where the local CPU alters memory contents. As such, manufacture and device codes must be accessible while the device resides in the target system. PROM programmers typically access the signature codes by raising A<sub>9</sub> to a high voltage. However multiplexing high voltage onto the address lines is not generally desired system design practice.

The device contains Autoselect command operation to supplement traditional PROM programming methodology. The operation is initiated by writing the Autoselect command sequence into the command register.

Following the command write, a read cycle from address (XX) 00h retrieves the manufacture code of 04h. A read cycle from address (XX) 01h for ×16 ((XX) 02h for ×8) returns the device code. A read cycle from address (XX) 03h for ×16 ((XX) 06h for ×8) returns the extended device code. (See “MBM29LV320TE/BE Sector Group Protection Verify Autoselect Codes Table” and “Extended Autoselect Code Table” in ■DEVICE BUS OPERATIONS.)

The sector state (protection or unprotection) is informed by address (XX) 02h for ×16 ((XX) 04h for ×8). Scanning the sector group addresses (A<sub>20</sub>, A<sub>19</sub>, A<sub>18</sub>, A<sub>17</sub>, A<sub>16</sub>, A<sub>15</sub>, A<sub>14</sub>, A<sub>13</sub>, and A<sub>12</sub>) while (A<sub>6</sub>, A<sub>1</sub>, A<sub>0</sub>) = (0, 1, 0) will produce a logic “1” at device output DQ<sub>0</sub> for a protected sector group. The programming verification should be performed by verify sector group protection on the protected sector. (See “MBM29LV320TE/BE User Bus Operations Tables (BYTE = V<sub>IH</sub> and BYTE = V<sub>IL</sub>)” in ■DEVICE BUS OPERATIONS.)

To terminate the operation, it is necessary to write the Read/Reset command sequence into the register. To execute the Autoselect command during the operation, writing Read/Reset command sequence must precede the Autoselect command.

### 3. Byte/Word Programming

The device is programmed on a byte-by-byte (or word-by-word) basis. Programming is a four bus cycle operation. There are two “unlock” write cycles. These are followed by the program set-up command and data write cycles. Addresses are latched on the falling edge of  $\overline{CE}$  or  $\overline{WE}$ , whichever happens later and the data is latched on the rising edge of  $\overline{CE}$  or  $\overline{WE}$ , whichever happens first. The rising edge of  $\overline{CE}$  or  $\overline{WE}$  (whichever happens first) begins programming. Upon executing the Embedded Program Algorithm command sequence, the system is not required to provide further controls or timings. The device automatically provides adequate internally generated program pulses and verify programmed cell margin.

The system can determine the status of the program operation by using DQ<sub>7</sub> ( $\overline{Data}$  Polling), DQ<sub>6</sub> (Toggle Bit), or RY/ $\overline{BY}$ . The  $\overline{Data}$  Polling and Toggle Bit must be performed at the memory location being programmed.

The automatic programming operation is completed when the data on DQ<sub>7</sub> is equivalent to data written to this bit at which the device return to the read mode and addresses are no longer latched. See “Hardware Sequence Flags Table”. Therefore the device requires that a valid address to the device be supplied by the system at this particular instance of time. Hence Data Polling must be performed at the memory location being programmed.

Any commands written to the chip during this period will be ignored. If hardware reset occurs during the programming operation, it is impossible to guarantee the data are being written.

Programming is allowed in any sequence and across sector boundaries. Beware that a data “0” cannot be programmed back to a “1”. Attempting to do so may either hang up the device or result in an apparent success according to the data polling algorithm but a read from Read/Reset mode will show that the data is still “0”. Only erase operations can convert “0”s to “1”s.

“1. Embedded Program™ Algorithm” in ■FLOW CHART illustrates the Embedded Program™ Algorithm using typical command strings and bus operations.

#### 4. Chip Erase

Chip erase is a six bus cycle operation. There are two “unlock” write cycles. These are followed by writing the “set-up” command. Two more “unlock” write cycles are then followed by the chip erase command.

Chip erase does not require the user to program prior to erase. Upon executing the Embedded Erase Algorithm command sequence the device automatically programs and verifies the entire memory for an all zero data pattern prior to electrical erase (Preprogram function). The system is not required to provide any controls or timings during these operations.

The system can determine the erase operation status by using DQ<sub>7</sub> (Data Polling), DQ<sub>6</sub> (Toggle Bit), or RY/B $\bar{Y}$ . The chip erase begins on the rising edge of the last  $\bar{C}E$  or  $\bar{W}E$ , whichever happens first in the command sequence and terminates when the data on DQ<sub>7</sub> is “1” (See “12. Write Operation Status”.) at which time the device returns to read the mode.

Chip Erase Time; Sector Erase Time × All sectors + Chip Program Time (Preprogramming)

“2. Embedded Erase™ Algorithm” in ■FLOW CHART illustrates the Embedded Erase™ Algorithm using typical command strings and bus operations.

#### 5. Sector Erase

Sector erase is a six bus cycle operation. There are two “unlock” write cycles. These are followed by writing the “set-up” command. Two more “unlock” write cycles are then followed by the Sector Erase command. The sector address (any address location within the desired sector) is latched on the falling edge of  $\bar{C}E$  or  $\bar{W}E$  whichever starts later, while the command (Data = 30h) is latched on the rising edge of  $\bar{C}E$  or  $\bar{W}E$  which happens first. After time-out of “t<sub>row</sub>” from the rising edge of the last sector erase command, the sector erase operation will begin.

Multiple sectors are erased concurrently by writing the six bus cycle operations on “MBM29LV320TE/BE Command Definitions Table” in ■DEVICE BUS OPERATIONS. This sequence is followed with writes of the Sector Erase command to addresses in other sectors desired to be concurrently erased. The time between writes must be less than “t<sub>row</sub>” otherwise that command will not be accepted and erasure will not start. It is recommended that processor interrupts be disabled during this time to guarantee this condition. The interrupts can be re-enabled after the last Sector Erase command is written. A time-out of “t<sub>row</sub>” from the rising edge of last  $\bar{C}E$  or  $\bar{W}E$  whichever starts first initiates the execution of the Sector Erase command(s). If another falling edge of  $\bar{C}E$  or  $\bar{W}E$ , whichever starts first occurs within the “t<sub>row</sub>” time-out window the timer is reset. (Monitor DQ<sub>3</sub> to determine if the sector erase timer window is still open, see “16. DQ<sub>3</sub>”, Sector Erase Timer.) Any command other than Sector Erase or Erase Suspend during this time-out period will reset the device to the read mode, ignoring the previous command string. Resetting the device once execution has begun will corrupt the data in the sector. In that case, restart the erase on those sectors and allow them to complete. (See “12. Write Operation Status” for Sector Erase Timer operation.) Loading the sector erase buffer may be done in any sequence and with any number of sectors (0 to 70).

Sector erase does not require the user to program the device prior to erase. The device automatically program all memory locations in the sector (s) to be erased prior to electrical erase (Preprogram function). When erasing

a sector or sectors the remaining unselected sectors are not affected. The system is not required to provide any controls or timings during these operations.

The system can determine the status of the erase operation by using DQ<sub>7</sub> ( $\overline{\text{Data}}$  Polling), DQ<sub>6</sub> (Toggle Bit), or RY/ $\overline{\text{BY}}$ .

The sector erase begins after the “t<sub>row</sub>” time out from the rising edge of  $\overline{\text{CE}}$  or  $\overline{\text{WE}}$  whichever starts first for the last sector erase command pulse and terminates when the data on DQ<sub>7</sub> is “1” (See “12. Write Operation Status”). at which the device return to the read mode.  $\overline{\text{Data}}$  polling and Toggle Bit must be performed at an address within any of the sectors being erased.

Multiple Sector Erase Time; [Sector Erase Time + Sector Program Time (Preprogramming)] × Number of Sector Erase

“2. Embedded Erase™ Algorithm” in ■FLOW CHART illustrates the Embedded Erase™ Algorithm using typical command strings and bus operations.

## 6. Erase Suspend/Resume

The Erase Suspend command allows the user to interrupt a Sector Erase operation and then perform data reads from or programs to a sector not being erased. This command is applicable ONLY during the Sector Erase operation which includes the time-out period for sector erase. The Erase Suspend command will be ignored if written during the Chip Erase operation or Embedded Program Algorithm. Writing the Erase Suspend command (B0h) during the Sector Erase time-out results in immediate termination of the time-out period and suspension of the erase operation.

Writing the Erase Resume command (30h) resumes the erase operation. The addresses are “DON'T CARES” when writing the Erase Suspend or Erase Resume command.

When the Erase Suspend command is written during the Sector Erase operation, the device will take a maximum of “t<sub>SPD</sub>” to suspend the erase operation. When the device has entered the erase-suspended mode, the RY/ $\overline{\text{BY}}$  output pin is at high impedance state and the DQ<sub>7</sub> bit is at logic “1”, and DQ<sub>6</sub> stops toggling. The user must use the address of the erasing sector for reading DQ<sub>6</sub> and DQ<sub>7</sub> to determine if the erase operation is suspended. Further writes of the Erase Suspend command are ignored.

When the erase operation is suspended, the device defaults to the erase-suspend-read mode. Reading data in this mode is the same as reading from the standard read mode except that the data must be read from sectors that have not been erase-suspended. Successively reading from the erase-suspended sector while the device is in the erase-suspend-read mode will cause DQ<sub>2</sub> to toggle. See “17. DQ<sub>2</sub>”.

After entering the erase-suspend-read mode, the users can program the device by writing the appropriate command sequence for Program. This program mode is known as the erase-suspend-program mode. Again, programming in this mode is the same as programming in the regular Program mode except that the data must be programmed to sectors that are not erase-suspended. Successively reading from the erase-suspended sector while the device is in the erase-suspend-program mode causes DQ<sub>2</sub> to toggle. The end of the erase-suspended Program operation is detected by the RY/ $\overline{\text{BY}}$  output pin,  $\overline{\text{Data}}$  polling of DQ<sub>7</sub> or by the Toggle Bit I (DQ<sub>6</sub>) which is the same as the regular Program operation. Note that DQ<sub>7</sub> must be read from the Program address while DQ<sub>6</sub> can be read from any address.

To resume the operation of Sector Erase, the Resume command (30h) should be written. Any further writes of the Resume command at this point is ignored. Another Erase Suspend command is written after the chip resumes erasing.

## 7. Extended Command

### (1) Fast Mode

Fast Mode function. This mode dispenses with the initial two unlock cycles required in the standard program command sequence by writing Fast Mode command into the command register. In this mode the required bus cycle for programming is two cycles instead of four bus cycles in standard program command. The read operation is also executed after exiting this mode. During the Fast mode, do not write any command other than the Fast program/Fast mode reset command. To exit this mode, it is necessary to write Fast Mode Reset command into the command register. (See “8. Embedded Program™ Algorithm for Fast Mode” in ■FLOW CHART.) The V<sub>CC</sub> active current is required even  $\overline{\text{CE}} = V_{\text{IH}}$  during Fast Mode.

## (2) Fast Programming

During Fast Mode, the programming can be executed with two bus cycles operation. The Embedded Program Algorithm is executed by writing program set-up command (A0h) and data write cycles (PA/PD). (See “8. Embedded Program™ Algorithm for Fast Mode” in ■FLOW CHART.)

## (3) CFI (Common Flash Memory Interface)

The CFI (Common Flash Memory Interface) specification outlines device and host system software interrogation handshake which allows specific vendor-specified software algorithms to be used for entire families of device. This allows device-independent, JEDEC ID-independent, and forward-and backward-compatible software support for the specified flash device families. See “Common Flash Memory Interface Code Table” in ■FLEXIBLE SECTOR-ERASE ARCHITECTURE for details.

The operation is initiated by writing the query command (98h) into the command register. Following the command write, a read cycle from specific address retrieves device information. Please note that output data of upper byte (DQ<sub>15</sub> to DQ<sub>8</sub>) is “0” in word mode (16 bit) read. See “Common Flash Memory Interface Code Table” in ■FLEXIBLE SECTOR-ERASE ARCHITECTURE. To terminate operation, it is necessary to write the read/reset command sequence into the register. (See “Common Flash Memory Interface Code Table” in ■FLEXIBLE SECTOR-ERASE ARCHITECTURE.)

## 8. HiddenROM Region

The HiddenROM feature provides a Flash memory region that the system may access through a new command sequence. This is primarily intended for customers who wish to use an Electronic Serial Number (ESN) in the device with the ESN protected against modification. Once the HiddenROM region is protected, any further modification of that region is impossible. This ensures the security of the ESN once the product is shipped to the field.

The HiddenROM region is 256 bytes in length and is stored at the same address of the “outermost” 8 K byte boot sector. The MBM29LV320TE occupies the address of the byte mode 3FFFC0h to 3FFFFFFh (word mode 1FFFE0h to 1FFFFFFh) and the MBM29LV320BE type occupies the address of the byte mode 000000h to 000080h (word mode 000000h to 000040h) . After the system writes Enter HiddenROM command sequence, the system can read the HiddenROM region by using the addresses normally occupied by the boot sector. That is, the device sends all commands that would normally be sent to the boot sector to the HiddenROM region. This mode of operation continues until the system issues the Exit HiddenROM command sequence, or until power is removed from the device. On power-up, or following a hardware reset, the device reverts to sending commands to the boot sector.

## 9. HiddenROM Entry Command

The device has a HiddenROM area with One Time Protect function. This area is to enter the security code and to unable the change of the code once set. Program/erase is possible in this area until it is protected. However once it is protected, it is impossible to unprotect so please use this with caution.

HiddenROM area is 256 byte and in the same address area of “outermost” 8 K byte boot block. Therefore, write the HiddenROM entry command sequence to enter the HiddenROM area. It is called as HiddenROM mode when the HiddenROM area appears.

Sector other than the boot block area could be read during HiddenROM mode. Read/Program of the HiddenROM area is possible during HiddenROM mode. Write the HiddenROM reset command sequence to exit the HiddenROM mode.

## 10. HiddenROM Program Command

To program the data to the HiddenROM area, write the HiddenROM program command sequence during HiddenROM mode. This command is the same as the program command in usual except to write the command during HiddenROM mode. Therefore the detection of completion method is the same as, using the DQ<sub>7</sub> data poling, DQ<sub>6</sub> toggle bit and RY/BY pin. Need to pay attention to the address to be programmed. If the address other than the HiddenROM area is selected to program, data of the address will be changed.

Please note that the sector erase command is prohibited during HiddenROM mode. If the sector erase command is appeared in this mode, data of the address will be erased.

## 11. HiddenROM Protect Command

There are two methods to protect the HiddenROM area. One of them is to write the sector group protect setup command (60h), set the sector address in the HiddenROM area and  $(A_6, A_1, A_0) = (0, 1, 0)$ , and write the sector group protect command (60h) during the HiddenROM mode. The same command sequence could be used because it is the same with the extension sector group protect except that it is in the HiddenROM mode and it does not apply high voltage to  $\overline{\text{RESET}}$  pin. Please see "9. Extended Sector Group Protection" in ■FUNCTIONAL DESCRIPTION for details of extension sector group protect setting.

The other is to apply high voltage ( $V_{ID}$ ) to  $A_9$  and  $\overline{\text{OE}}$ , set the sector address in the HiddenROM area and  $(A_6, A_1, A_0) = (0, 1, 0)$ , and apply the write pulse during the HiddenROM mode. To verify the protect circuit, apply high voltage ( $V_{ID}$ ) to  $A_9$ , specify  $(A_6, A_1, A_0) = (0, 1, 0)$  and the sector address in the HiddenROM area, and read. When "1" appears on  $DQ_0$ , the protect setting is completed. "0" will appear on  $DQ_0$  if it is not protected. Please apply write pulse again. The same command sequence could be used for the above method because other than the HiddenROM mode, it is the same as the sector group protect in the past. Please see "7. Sector Group Protection" in ■FUNCTIONAL DESCRIPTION for details of the sector group protect setting.

Other sector group will be effected if the address other than those for HiddenROM area is selected for the sector group address, so please be careful. Once it is protected, protection can not be cancelled, so please pay the closest attention.

## 12. Write Operation Status

Details in "Hardware Sequence Flags Table" are all the status flags that can be used to check the status of the device for current mode operation. During sector erase, the part provides the status flags automatically to the I/O ports. The information on  $DQ_2$  is address sensitive. This means that if an address from an erasing sector is consecutively read, then the  $DQ_2$  bit will toggle. However,  $DQ_2$  will not toggle if an address from a non-erasing sector is consecutively read. This allows users to determine which sectors are in erase.

Once erase suspend is entered, address sensitivity still applies. If the address of a non-erasing sector (that is, one available for read) is provided, then stored data can be read from the device. If the address of an erasing sector (that is, one unavailable for read) is applied, the device will output its status bits.

**Hardware Sequence Flags Table**

Status		$\overline{DQ}_7$	$DQ_6$	$DQ_5$	$DQ_3$	$DQ_2$	
In Progress	Embedded Program Algorithm	$\overline{DQ}_7$	Toggle	0	0	1	
	Embedded Erase Algorithm	0	Toggle	0	1	Toggle *1	
	Erase Suspended Mode	Erase Suspend Read (Erase Suspended Sector)	1	1	0	0	Toggle
		Erase Suspend Read (Non-Erase Suspended Sector)	Data	Data	Data	Data	Data
	Erase Suspend Program (Non-Erase Suspended Sector)	$\overline{DQ}_7$	Toggle	0	0	1 *2	
Exceeded Time Limits	Embedded Program Algorithm	$\overline{DQ}_7$	Toggle	1	0	1	
	Embedded Erase Algorithm	0	Toggle	1	1	N/A	
	Erase Suspended Mode	Erase Suspend Program (Non-Erase Suspended Sector)	$\overline{DQ}_7$	Toggle	1	0	N/A

\*1: Successive reads from the erasing or erase-suspend sector cause  $DQ_2$  to toggle.

\*2: Reading from non-erase suspend sector address indicates logic "1" at the  $DQ_2$  bit.

## 13. DQ<sub>7</sub>

### Data Polling

The device features  $\overline{\text{Data}}$  Polling as a method to indicate to the host that the Embedded Algorithms are in progress or completed. During the Embedded Program Algorithm an attempt to read the device produces a complement of data last written to DQ<sub>7</sub>. Upon completion of the Embedded Program Algorithm, an attempt to read device produces true data last written to DQ<sub>7</sub>. During the Embedded Erase Algorithm, an attempt to read device produces a “0” at the DQ<sub>7</sub> output. Upon completion of the Embedded Erase Algorithm an attempt to read device produces a “1” on DQ<sub>7</sub>. The flowchart for  $\overline{\text{Data}}$  Polling (DQ<sub>7</sub>) is shown in “3.  $\overline{\text{Data}}$  Polling Algorithm” ( ■FLOW CHART).

For programming, the  $\overline{\text{Data}}$  Polling is valid after the rising edge of the fourth write pulse in the four write pulse sequence.

For chip erase and sector erase, the  $\overline{\text{Data}}$  Polling is valid after the rising edge of the sixth write pulse in the six write pulse sequence.  $\overline{\text{Data}}$  Polling must be performed at sector address within any of the sectors being erased, not a protected sectors. Otherwise, the status may be invalid.

Once the Embedded Algorithm operation is close to being completed, the device data pins (DQ<sub>7</sub>) may change asynchronously while the output enable ( $\overline{\text{OE}}$ ) is asserted low. This means that the device is driving status information on DQ<sub>7</sub> at one instant of time and then that byte's valid data the next instant of time. Depending on when the system samples the DQ<sub>7</sub> output, it may read the status or valid data. Even if the device has completed the Embedded Algorithm operation and DQ<sub>7</sub> has a valid data, the data outputs on DQ<sub>0</sub> to DQ<sub>6</sub> may be still invalid. The valid data on DQ<sub>0</sub> to DQ<sub>7</sub> will be read on the successive read attempts.

The  $\overline{\text{Data}}$  Polling feature is only active during the Embedded Programming Algorithm, Embedded Erase Algorithm, Erase Suspend mode or sector erase time-out. (See “Hardware Sequence Flags” Table.)

See “6.  $\overline{\text{Data}}$  Polling during Embedded Algorithm Operation Timing Diagram” in ■TIMING DIAGRAM for the  $\overline{\text{Data}}$  Polling timing specifications and diagrams.

## 14. DQ<sub>6</sub>

### Toggle Bit I

The device also features the “Toggle Bit I” as a method to indicate to the host system that the Embedded Algorithms are in progress or completed.

During Embedded Program or Erase Algorithm cycle, successive attempts to read ( $\overline{\text{CE}}$  or  $\overline{\text{OE}}$  toggling) data from the device results in DQ<sub>6</sub> toggling between one and zero. Once the Embedded Program or Erase Algorithm cycle is completed, DQ<sub>6</sub> stops toggling and valid data is read on the next successive attempts. During programming, the Toggle Bit I is valid after the rising edge of the fourth write pulse in the four write pulse sequence. For chip erase and sector erase, the Toggle Bit I is valid after the rising edge of the sixth write pulse in the six write pulse sequence. The Toggle Bit I is active during the sector time out.

In program operation, if the sector being written to be protected, the toggle bit toggles for about 1  $\mu\text{s}$  and then stops toggling with data unchanged. In erase operation, the device erases all selected sectors except for ones that are protected. If all selected sectors are protected, chip toggles the toggle bit for about 400  $\mu\text{s}$  and then drop back into read mode, having data unchanged.

Either  $\overline{\text{CE}}$  or  $\overline{\text{OE}}$  toggling causes DQ<sub>6</sub> to toggle.

See “7. Toggle Bit I during Embedded Algorithm Operation Timing Diagram” in ■TIMING DIAGRAM for the Toggle Bit I timing specifications and diagrams.

## 15. DQ<sub>5</sub>

### Exceeded Timing Limits

DQ<sub>5</sub> indicates if the program or erase time has exceeded the specified limits (internal pulse count) . Under these conditions DQ<sub>5</sub> produces a “1”. This is a failure condition which indicates that the program or erase cycle was not successfully completed.  $\overline{\text{Data}}$  Polling is the only operating function of device under this condition. The  $\overline{\text{CE}}$  circuit partially powers down device under these conditions (to approximately 2 mA) . The  $\overline{\text{OE}}$  and WE pins

control the output disable functions as described in “MBM29LV320TE/BE User Bus Operations Tables ( $\overline{\text{BYTE}} = V_{IH}$  and  $\overline{\text{BYTE}} = V_{IL}$ )” (■DEVICE BUS OPERATIONS).

The DQ<sub>5</sub> failure condition may also appear if a user tries to program a non blank location without erasing. In this case the device locks out and never complete the Embedded Algorithm operation. Hence, the system never read valid data on DQ<sub>7</sub> bit and DQ<sub>6</sub> never stop toggling. Once the device has exceeded timing limits, the DQ<sub>5</sub> bit indicates a “1.” Please note that this is not a device failure condition since device was incorrectly used. If this occurs, reset device with command sequence.

## 16. DQ<sub>3</sub>

### Sector Erase Timer

After completion of the initial sector erase command sequence the sector erase time-out will begin. DQ<sub>3</sub> remains low until the time-out is completed.  $\overline{\text{Data}}$  Polling and Toggle Bit are valid after the initial sector erase command sequence.

If  $\overline{\text{Data}}$  Polling or Toggle Bit I indicates device has been written with a valid erase command, DQ<sub>3</sub> may be used to determine if the sector erase timer window is still open. If DQ<sub>3</sub> is high (“1”) the internally controlled erase cycle has begun; attempts to write subsequent commands to the device be ignored until the erase operation is completed as indicated by  $\overline{\text{Data}}$  Polling or Toggle Bit I. If DQ<sub>3</sub> is low (“0”), the device will accept additional sector erase commands. To insure the command has been accepted, the system software should check the status of DQ<sub>3</sub> prior to and following each subsequent Sector Erase command. If DQ<sub>3</sub> were high on the second status check, the command may not have been accepted.

See “Hardware Sequence Flags Table”.

## 17. DQ<sub>2</sub>

### Toggle Bit II

This toggle bit II, along with DQ<sub>6</sub>, can be used to determine whether the device is in the Embedded Erase Algorithm or in Erase Suspend.

Successive reads from the erasing sector cause DQ<sub>2</sub> to toggle during the Embedded Erase Algorithm. If the device is in the erase-suspended-read mode, successive reads from the erase-suspended sector causes DQ<sub>2</sub> to toggle. When the device is in the erase-suspended-program mode, successive reads from the byte address of the non-erase suspended sector indicate a logic “1” at the DQ<sub>2</sub> bit.

DQ<sub>6</sub> is different from DQ<sub>2</sub> in that DQ<sub>6</sub> toggles only when the standard program or erase, or erase suspend program operation is in progress. The behavior of these two status bits, along with that of DQ<sub>7</sub>, is summarized as follows :

For example, DQ<sub>2</sub> and DQ<sub>6</sub> are used together to determine if the erase-suspend-read mode is in progress. (DQ<sub>2</sub> toggles while DQ<sub>6</sub> does not.) See also “Toggle Bit Status Table” and “8. DQ<sub>2</sub> vs DQ<sub>6</sub>” in ■TIMING DIAGRAM.

Furthermore, DQ<sub>2</sub> is used to determine which sector is being erased. When the device is in the erase mode, DQ<sub>2</sub> toggles if this bit is read from an erasing sector.

## 18. Reading Toggle Bits DQ<sub>6</sub>/DQ<sub>2</sub>

Whenever the system initially begins reading toggle bit status, it must read DQ<sub>7</sub> to DQ<sub>0</sub> at least twice in a row to determine whether a toggle bit is toggling. Typically, a system would note and store the value of the toggle bit after the first read. After the second read, the system would compare the new value of the toggle bit with the first read. If the toggle bit is not toggling, indicates that the device has completed the program or erase operation. The system can read array data on DQ<sub>7</sub> to DQ<sub>0</sub> on the following read cycle.

However if after the initial two read cycles, the system determines that the toggle bit is still toggling, the system also should note whether the value of DQ<sub>5</sub> is high (see “15. DQ<sub>5</sub>”). If it is the system should then determine again whether the toggle bit is toggling, since the toggle bit may have stopped toggling just as DQ<sub>5</sub> went high. If the toggle bit is no longer toggling, the device has successfully completed the program or erase operation. If it is still toggling, the device did not complete the operation successfully, and the system must write the reset command to return to reading array data.

The remaining scenario is that the system initially determines that the toggle bit is toggling and DQ<sub>5</sub> has not gone high. The system may continue to monitor the toggle bit and DQ<sub>5</sub> through successive read cycles, determining the status as described in the previous paragraph. Alternatively, the system may choose to perform other system tasks. In this case, the system must start at the beginning of the algorithm when it returns to determine the status of the operation. See “4. Toggle Bit Algorithm” in ■FLOW CHART.

**Toggle Bit Status Table**

Mode	DQ <sub>7</sub>	DQ <sub>6</sub>	DQ <sub>2</sub>
Program	$\overline{DQ_7}$	Toggle	1
Erase	0	Toggle	Toggle* <sup>1</sup>
Erase-Suspend Read (Erase-Suspended Sector)	1	1	Toggle
Erase-Suspend Program	$\overline{DQ_7}$	Toggle	1* <sup>2</sup>

\*1 : Successive reads from the erasing or erase-suspend sector cause DQ<sub>2</sub> to toggle.

\*2 : Reading from non-erase suspend sector address indicates logic “1” at the DQ<sub>2</sub> bit.

## 19. RY/ $\overline{BY}$

### Ready/Busy

The device provides a RY/ $\overline{BY}$  open-drain output pin as a way to indicate to the host system that the Embedded Algorithms are either in progress or has been completed. If output is low, the device is busy with either a program or erase operation. If output is high, the device is ready to accept any read/write or erase operation. When the RY/ $\overline{BY}$  pin is low, the device will not accept any additional program or erase commands. If the device is placed in an Erase Suspend mode, RY/ $\overline{BY}$  output is high.

During programming, RY/ $\overline{BY}$  pin is driven low after the rising edge of the fourth write pulse. During an erase operation, RY/ $\overline{BY}$  pin is driven low after the rising edge of the sixth write pulse. RY/ $\overline{BY}$  pin indicates a busy condition during  $\overline{RESET}$  pulse. See “9. RY/ $\overline{BY}$  Timing Diagram during Program/Erase operations” and “10.  $\overline{RESET}$ , RY/ $\overline{BY}$  Timing Diagram” in ■TIMING DIAGRAM for a detailed timing diagram. RY/ $\overline{BY}$  pin is pulled high in standby mode.

Since this is an open-drain output, the pull-up resistor needs to be connected to V<sub>CC</sub>; multiples of devices may be connected to the host system via more than one RY/ $\overline{BY}$  pin in parallel.

## 20. Byte/Word Configuration

$\overline{BYTE}$  pin selects byte (8-bit) mode or word (16-bit) mode for device. When this pin is driven high, the device operates in word (16-bit) mode. Data is read and programmed at DQ<sub>15</sub> to DQ<sub>0</sub>. When this pin is driven low, the device operates in byte (8-bit) mode. Under this mode, DQ<sub>15</sub>/A<sub>-1</sub> pin becomes the lowest address bit, and DQ<sub>14</sub> to DQ<sub>8</sub> bits are tri-stated. However, the command bus cycle is always an 8-bit operation and hence commands are written at DQ<sub>15</sub> to DQ<sub>8</sub> and the DQ<sub>7</sub> to DQ<sub>0</sub> bits are ignored. See “11. Word Mode Configuration Timing Diagram”, “12. Byte Mode Configuration Timing Diagram” and “13.  $\overline{BYTE}$  Timing Diagram for Write Operations” in ■TIMING DIAGRAM the detail .

## 21. Data Protection

The device is designed to offer protection against accidental erasure or programming caused by spurious system level signals that may exist during power transitions. During power up device automatically resets internal state machine in Read mode. Also, with its control register architecture, alteration of memory contents only occurs after successful completion of specific multi-bus cycle command sequences.

The device also incorporates several features to prevent inadvertent write cycles resulting from V<sub>CC</sub> power-up and power-down transitions or system noise.

## 22. Low V<sub>CC</sub> Write Inhibit

To avoid initiation of a write cycle during V<sub>CC</sub> power-up and power-down, write cycle is locked out for V<sub>CC</sub> less than V<sub>LKO</sub> (Min) . If V<sub>CC</sub> < V<sub>LKO</sub>, the command register is disabled and all internal program/erase circuits are disabled. Under this condition the device resets to the read mode. Subsequent writes are ignored until the V<sub>CC</sub> level is greater than V<sub>LKO</sub>. It is the users responsibility to ensure that the control pins are logically correct to prevent unintentional writes when V<sub>CC</sub> is above V<sub>LKO</sub> (Min) .

If Embedded Erase Algorithm is interrupted, there is possibility that the erasing sector (s) cannot be used.

## 23. Write Pulse “Glitch” Protection

Noise pulses of less than 3 ns (Typ) on  $\overline{OE}$ ,  $\overline{CE}$ , or  $\overline{WE}$  does not initiate write cycle.

## 24. Logical Inhibit

Writing is inhibited by holding any one of  $\overline{OE} = V_{IL}$ ,  $\overline{CE} = V_{IH}$ , or  $\overline{WE} = V_{IH}$ . To initiate a write cycle  $\overline{CE}$  and  $\overline{WE}$  must be logical zero while  $\overline{OE}$  is a logical one.

## 25. Power-Up Write Inhibit

Power-up of the device with  $\overline{WE} = \overline{CE} = V_{IL}$  and  $\overline{OE} = V_{IH}$  does not accept commands on the rising edge of  $\overline{WE}$ . The internal state machine is automatically reset to the read mode on power-up.

## 26. Sector Group Protection

Device user is able to protect each sector group individually to store and protect data. Protection circuit voids both write and erase commands that are addressed to protected sectors.

Any commands to write or erase addressed to protected sector are ignore. (See “7. Sector Group Protection” in ■FUNCTIONAL DESCRIPTION.)

# MBM29LV320TE/BE<sub>80/90/10</sub>

## ■ ABSOLUTE MAXIMUM RATINGS

Parameter	Symbol	Rating		Unit
		Min	Max	
Storage Temperature	T <sub>stg</sub>	-55	+125	°C
Ambient Temperature with Power Applied	T <sub>A</sub>	-40	+85	°C
Voltage with Respect to Ground All pins except A <sub>9</sub> , $\overline{OE}$ , and $\overline{RESET}$ *1, *2	V <sub>IN</sub> , V <sub>OUT</sub>	-0.5	V <sub>CC</sub> + 0.5	V
Power Supply Voltage *1	V <sub>CC</sub>	-0.5	+4.0	V
A <sub>9</sub> , $\overline{OE}$ , and $\overline{RESET}$ *1, *3	V <sub>IN</sub>	-0.5	+13.0	V
$\overline{WP}/ACC$ *1, *4	V <sub>ACC</sub>	-0.5	+13.0	V

\*1 : Voltage is defined on the basis of V<sub>SS</sub> = GND = 0 V.

\*2 : Minimum DC voltage on input or I/O pins is -0.5 V. During voltage transitions, input or I/O pins may undershoot V<sub>SS</sub> to -2.0 V for periods of up to 20 ns. Maximum DC voltage on input or I/O pins is V<sub>CC</sub> + 0.5 V. During voltage transitions, input or I/O pins may overshoot to V<sub>CC</sub> + 2.0 V for periods of up to 20 ns.

\*3 : Minimum DC input voltage on A<sub>9</sub>,  $\overline{OE}$  and  $\overline{RESET}$  pins is -0.5 V. During voltage transitions, A<sub>9</sub>,  $\overline{OE}$  and  $\overline{RESET}$  pins may undershoot V<sub>SS</sub> to -2.0 V for periods of up to 20 ns. Voltage difference between input and supply voltage (V<sub>IN</sub> - V<sub>CC</sub>) does not exceed +9.0 V. Maximum DC input voltage on A<sub>9</sub>,  $\overline{OE}$  and  $\overline{RESET}$  pins is +13.0 V which may overshoot to +14.0 V for periods of up to 20 ns.

\*4 : Minimum DC input voltage on  $\overline{WP}/ACC$  pin is -0.5 V. During voltage transitions,  $\overline{WP}/ACC$  pin may undershoot V<sub>SS</sub> to -2.0 V for periods of up to 20 ns. Maximum DC input voltage on  $\overline{WP}/ACC$  pin is +13.0 V which may overshoot to +12.0 V for periods of up to 20 ns when V<sub>CC</sub> is applied.

WARNING: Semiconductor devices can be permanently damaged by application of stress (voltage, current, temperature, etc.) in excess of absolute maximum ratings. Do not exceed these ratings.

## ■ RECOMMENDED OPERATING CONDITIONS

Parameter	Symbol	Part No.	Value		Unit
			Min	Max	
Ambient Temperature	T <sub>A</sub>	MBM29LV320TE/BE 80/90/10	-40	+85	°C
Power Supply Voltage*	V <sub>CC</sub>	MBM29LV320TE/BE 80/90	+3.0	+3.6	V
		MBM29LV320TE/BE 10	+2.7	+3.6	

\* : Voltage is defined on the basis of V<sub>SS</sub> = GND = 0 V.

WARNING: The recommended operating conditions are required in order to ensure the normal operation of the semiconductor device. All of the device's electrical characteristics are warranted when the device is operated within these ranges.

Always use semiconductor devices within their recommended operating condition ranges. Operation outside these ranges may adversely affect reliability and could result in device failure.

No warranty is made with respect to uses, operating conditions, or combinations not represented on the data sheet. Users considering application outside the listed conditions are advised to contact their FUJITSU representatives beforehand.

## ■ MAXIMUM OVERSHOOT/MAXIMUM UNDERSHOOT

**Maximum Undershoot Waveform**

**Maximum Overshoot Waveform 1**

Note : This waveform is applied for  $A_9$ ,  $\overline{OE}$ , and  $\overline{RESET}$ .

**Maximum Overshoot Waveform 2**

The contents of this document are subject to change without notice. Customers are advised to consult with FUJITSU sales representatives before ordering.

The information, such as descriptions of function and application circuit examples, in this document are presented solely for the purpose of reference to show examples of operations and uses of Fujitsu semiconductor device; Fujitsu does not warrant proper operation of the device with respect to use based on such information. When you develop equipment incorporating the device based on such information, you must assume any responsibility arising out of such use of the information. Fujitsu assumes no liability for any damages whatsoever arising out of the use of the information.

Any information in this document, including descriptions of function and schematic diagrams, shall not be construed as license of the use or exercise of any intellectual property right, such as patent right or copyright, or any other right of Fujitsu or any third party or does Fujitsu warrant non-infringement of any third-party's intellectual property right or other right by using such information. Fujitsu assumes no liability for any infringement of the intellectual property rights or other rights of third parties which would result from the use of information contained herein.

The products described in this document are designed, developed and manufactured as contemplated for general use, including without limitation, ordinary industrial use, general office use, personal use, and household use, but are not designed, developed and manufactured as contemplated (1) for use accompanying fatal risks or dangers that, unless extremely high safety is secured, could have a serious effect to the public, and could lead directly to death, personal injury, severe physical damage or other loss (i.e., nuclear reaction control in nuclear facility, aircraft flight control, air traffic control, mass transport control, medical life support system, missile launch control in weapon system), or (2) for use requiring extremely high reliability (i.e., submersible repeater and artificial satellite).

Please note that Fujitsu will not be liable against you and/or any third party for any claims or damages arising in connection with above-mentioned uses of the products.

Any semiconductor devices have an inherent chance of failure. You must protect against injury, damage or loss from such failures by incorporating safety design measures into your facility and equipment such as redundancy, fire protection, and prevention of over-current levels and other abnormal operating conditions.

If any products described in this document represent goods or technologies subject to certain restrictions on export under the Foreign Exchange and Foreign Trade Law of Japan, the prior authorization by Japanese government will be required for export of those products from Japan.
