Stress beyond those listed may affect device reliability or cause permanent damage to the device. See Section 8, "Power Supply and Power Sequencing."

**Caution:** All inputs that tolerate 5 V cannot be more than 2.5 V greater than VDDH. This restriction applies to power up and normal operation (that is, if the MPC885/880 is unpowered, a voltage greater than 2.5 V must not be applied to its inputs).

## 7 Thermal Calculation and Measurement

For the following discussions,  $P_D = (V_{DDL} \times I_{DDL}) + PI/O$ , where PI/O is the power dissipation of the I/O drivers.

### NOTE

The  $V_{DDSYN}$  power dissipation is negligible.

### 7.1 Estimation with Junction-to-Ambient Thermal Resistance

An estimation of the chip junction temperature,  $T_J$ , in °C can be obtained from the following equation:

$$T_J = T_A + (R_{\theta JA} \times P_D)$$

where:

$T_A$  = ambient temperature °C

$R_{\theta JA}$  = package junction-to-ambient thermal resistance (°C/W)

$P_D$  = power dissipation in package

The junction-to-ambient thermal resistance is an industry standard value that provides a quick and easy estimation of thermal performance. However, the answer is only an estimate; test cases have demonstrated that errors of a factor of two (in the quantity  $T_J - T_A$ ) are possible.

### 7.2 Estimation with Junction-to-Case Thermal Resistance

Historically, thermal resistance has frequently been expressed as the sum of a junction-to-case thermal resistance and a case-to-ambient thermal resistance:

$$R_{\theta JA} = R_{\theta JC} + R_{\theta CA}$$

where:

$R_{\theta JA}$  = junction-to-ambient thermal resistance (°C/W)

$R_{\theta JC}$  = junction-to-case thermal resistance (°C/W)

$R_{\theta CA}$  = case-to-ambient thermal resistance (°C/W)

$R_{\theta JC}$  is device-related and cannot be influenced by the user. The user adjusts the thermal environment to affect the case-to-ambient thermal resistance,  $R_{\theta CA}$ . For instance, the user can change the airflow around the device, add a heat sink, change the mounting arrangement on the printed circuit board, or change the thermal dissipation on the printed circuit board surrounding the device. This thermal model is most useful for ceramic packages with heat sinks where some 90% of the heat flows through the case and the heat sink to the ambient environment. For most packages, a better model is required.

### 7.3 Estimation with Junction-to-Board Thermal Resistance

A simple package thermal model that has demonstrated reasonable accuracy (about 20%) is a two-resistor model consisting of a junction-to-board and a junction-to-case thermal resistance. The junction-to-case covers the situation where a heat sink is used or where a substantial amount of heat is dissipated from the top of the package. The junction-to-board thermal resistance describes the thermal performance when most of the heat is conducted to the printed circuit board. It has been observed that the thermal performance of most plastic packages and especially PBGA packages is strongly dependent on the board temperature; see Figure 3.

Figure 3. Effect of Board Temperature Rise on Thermal Behavior

If the board temperature is known, an estimate of the junction temperature in the environment can be made using the following equation:

$$T_J = T_B + (R_{\theta JB} \times P_D)$$

where:

$R_{\theta JB}$  = junction-to-board thermal resistance ( $^{\circ}\text{C}/\text{W}$ )

$T_B$  = board temperature  $^{\circ}\text{C}$

$P_D$  = power dissipation in package

If the board temperature is known and the heat loss from the package case to the air can be ignored, acceptable predictions of junction temperature can be made. For this method to work, the board and board mounting must be similar to the test board used to determine the junction-to-board thermal resistance, namely a 2s2p (board with a power and a ground plane) and vias attaching the thermal balls to the ground plane.

### 7.4 Estimation Using Simulation

When the board temperature is not known, a thermal simulation of the application is needed. The simple two resistor model can be used with the thermal simulation of the application [2], or a more accurate and complex model of the package can be used in the thermal simulation.

## 7.5 Experimental Determination

To determine the junction temperature of the device in the application after prototypes are available, the thermal characterization parameter ( $\Psi_{JT}$ ) can be used to determine the junction temperature with a measurement of the temperature at the top center of the package case using the following equation:

$$T_J = T_T + (\Psi_{JT} \times P_D)$$

where:

$\Psi_{JT}$  = thermal characterization parameter

$T_T$  = thermocouple temperature on top of package

$P_D$  = power dissipation in package

The thermal characterization parameter is measured per the JESD51-2 specification published by JEDEC using a 40 gauge type T thermocouple epoxied to the top center of the package case. The thermocouple should be positioned so that the thermocouple junction rests on the package. A small amount of epoxy is placed over the thermocouple junction and over about 1 mm of wire extending from the junction. The thermocouple wire is placed flat against the package case to avoid measurement errors caused by the cooling effects of the thermocouple wire.

## 8 Power Supply and Power Sequencing

This section provides design considerations for the MPC885/880 power supply. The MPC885/880 has a core voltage ( $V_{DDL}$ ) and PLL voltage ( $V_{DDSYN}$ ), which both operate at a lower voltage than the I/O voltage  $V_{DDH}$ . The I/O section of the MPC885/880 is supplied with 3.3 V across  $V_{DDH}$  and  $V_{SS}$  (GND).

The signals PA[0:15], PB[14:31], PC[4:15], PD[3:15], TDI, TDO, TCK, TRST\_B, TMS, MII\_TXEN, and MII\_MDIO are 5-V tolerant. All inputs cannot be more than 2.5 V greater than  $V_{DDH}$ . In addition, 5-V tolerant pins can not exceed 5.5 V and remaining input pins cannot exceed 3.465 V. This restriction applies to power up/down and normal operation.

One consequence of multiple power supplies is that when power is initially applied the voltage rails ramp up at different rates. The rates depend on the nature of the power supply, the type of load on each power supply, and the manner in which different voltages are derived. The following restrictions apply:

- $V_{DDL}$  must not exceed  $V_{DDH}$  during power up and power down.
- $V_{DDL}$  must not exceed 1.9 V, and  $V_{DDH}$  must not exceed 3.465 V.

These cautions are necessary for the long-term reliability of the part. If they are violated, the electrostatic discharge (ESD) protection diodes are forward-biased, and excessive current can flow through these diodes. If the system power supply design does not control the voltage sequencing, the circuit shown Figure 4 can be added to meet these requirements. The MUR420 Schottky diodes control the maximum potential difference between the external bus and core power supplies on power up, and the 1N5820 diodes regulate the maximum potential difference on power down.

Figure 4. Example Voltage Sequencing Circuit

## 9 Layout Practices

Each  $V_{DD}$  pin on the MPC885/880 should be provided with a low-impedance path to the board's supply. Each GND pin should likewise be provided with a low-impedance path to ground. The power supply pins drive distinct groups of logic on chip. The  $V_{DD}$  power supply should be bypassed to ground using at least four 0.1  $\mu\text{F}$  by-pass capacitors located as close as possible to the four sides of the package. Each board designed should be characterized and additional appropriate decoupling capacitors should be used if required. The capacitor leads and associated printed circuit traces connecting to chip  $V_{DD}$  and GND should be kept to less than half an inch per capacitor lead. At a minimum, a four-layer board employing two inner layers as  $V_{DD}$  and GND planes should be used.

All output pins on the MPC885/880 have fast rise and fall times. Printed circuit (PC) trace interconnection length should be minimized in order to minimize undershoot and reflections caused by these fast output switching times. This recommendation particularly applies to the address and data buses. Maximum PC trace lengths of six inches are recommended. Capacitance calculations should consider all device loads as well as parasitic capacitances due to the PC traces. Attention to proper PCB layout and bypassing becomes especially critical in systems with higher capacitive loads because these loads create higher transient currents in the  $V_{DD}$  and GND circuits. Pull up all unused inputs or signals that will be inputs during reset. Special care should be taken to minimize the noise levels on the PLL supply pins. For more information, please refer to the *MPC885 User's Manual*, Section 14.4.3, "Clock Synthesizer Power ( $V_{DDSYN}$ ,  $V_{SSSYN}$ ,  $V_{SSSYN1}$ )".

## 10 Bus Signal Timing

The maximum bus speed supported by the MPC885/880 is 80 MHz. Higher-speed parts must be operated in half-speed bus mode (for example, an MPC885/880 used at 133 MHz must be configured for a 66 MHz bus). Table 7 shows the frequency ranges for standard part frequencies in 1:1 bus mode, and Table 8 shows the frequency ranges for standard part frequencies in 2:1 bus mode.

**Table 7. Frequency Ranges for Standard Part Frequencies (1:1 Bus Mode)**

Part Frequency	66 MHz		80 MHz	
	Min	Max	Min	Max
Core frequency	40	66.67	40	80
Bus frequency	40	66.67	40	80

**Table 8. Frequency Ranges for Standard Part Frequencies (2:1 Bus Mode)**

Part Frequency	66 MHz		80 MHz		133 MHz	
	Min	Max	Min	Max	Min	Max
Core frequency	40	66.67	40	80	40	133
Bus frequency	20	33.33	20	40	20	66

Table 9 provides the timings for the MPC885/880 at 33-, 40-, 66-, and 80-MHz bus operation.

The timing for the MPC885/880 bus shown assumes a 50-pF load for maximum delays and a 0-pF load for minimum delays. CLKOUT assumes a 100-pF load maximum delay.

Num	Characteristic	33 MHz		40 MHz		66 MHz		80 MHz		Unit
		Min	Max	Min	Max	Min	Max	Min	Max

B43	$\overline{AS}$ negation to memory controller signals negation (MAX = TBD)	—	TBD	—	TBD	—	TBD	—	TBD	ns

<sup>1</sup> For part speeds above 50 MHz, use 9.80 ns for B11a.

<sup>2</sup> The timing required for  $\overline{BR}$  input is relevant when the MPC885/880 is selected to work with the internal bus arbiter. The timing for  $\overline{BG}$  input is relevant when the MPC885/880 is selected to work with the external bus arbiter.

<sup>3</sup> For part speeds above 50 MHz, use 2 ns for B17.

<sup>4</sup> The D(0:31) input timings B18 and B19 refer to the rising edge of the CLKOUT in which the  $\overline{TA}$  input signal is asserted.

<sup>5</sup> For part speeds above 50 MHz, use 2 ns for B19.

<sup>6</sup> The D(0:31) input timings B20 and B21 refer to the falling edge of the CLKOUT. This timing is valid only for read accesses controlled by chip-selects under control of the user-programmable machine (UPM) in the memory controller, for data beats where DLT3 = 1 in the RAM words. (This is only the case where data is latched on the falling edge of CLKOUT.)

<sup>7</sup> The timing B30 refers to  $\overline{CS}$  when ACS = 00 and to  $\overline{WE}(0:3)$  when CSNT = 0.

<sup>8</sup> The signal UPWAIT is considered asynchronous to the CLKOUT and synchronized internally. The timings specified in B37 and B38 are specified to enable the freeze of the UPM output signals as described in Figure 20.

<sup>9</sup> The  $\overline{AS}$  signal is considered asynchronous to the CLKOUT. The timing B39 is specified in order to allow the behavior specified in Figure 23.

I40	$\overline{\text{IRQ}}_x$ hold time after CLKOUT	2.00		ns

<sup>1</sup> The I39 and I40 timings describe the testing conditions under which the  $\overline{\text{IRQ}}$  lines are tested when being defined as level sensitive. The  $\overline{\text{IRQ}}$  lines are synchronized internally and do not have to be asserted or negated with reference to the CLKOUT.

The I41, I42, and I43 timings are specified to allow correct functioning of the  $\overline{\text{IRQ}}$  lines detection circuitry and have no direct relation with the total system interrupt latency that the MPC885/880 is able to support.

These synchronous timings define when the  $\overline{\text{WAITx}}$  signals are detected in order to freeze (or relieve) the PCMCIA current cycle. The  $\overline{\text{WAITx}}$  assertion will be effective only if it is detected 2 cycles before the PSL timer expiration. ## 15 FEC Electrical Characteristics

This section provides the AC electrical specifications for the fast Ethernet controller (FEC). Note that the timing specifications for the MII signals are independent of system clock frequency (part speed designation). Also, MII signals use TTL signal levels compatible with devices operating at either 5.0 V or 3.3 V.

## 15.1 MII and Reduced MII Receive Signal Timing

The receiver functions correctly up to a MII\_RX\_CLK maximum frequency of 25 MHz + 1%. The reduced MII (RMII) receiver functions correctly up to a RMII\_REFCLK maximum frequency of 50 MHz + 1%. There is no minimum frequency requirement. In addition, the processor clock frequency must exceed the MII\_RX\_CLK frequency - 1%.

# 16.2 Mechanical Dimensions of the PBGA Package

Figure 77 shows the mechanical dimensions of the PBGA package.

**NOTES:**

1. ALL DIMENSIONS ARE IN MILLIMETERS.
2. INTERPRET DIMENSIONS AND TOLERANCES PER ASME Y14.5M-1994.
3. MAXIMUM SOLDER BALL DIAMETER MEASURED PARALLEL TO DATUM A.
4. DATUM A, THE SEATING PLANE, IS DEFINED BY THE SPHERICAL CROWNS OF THE SOLDER BALLS.

# 17 Document Revision History

Table 40 lists significant changes between revisions of this hardware specification.

**Table 40. Document Revision History**

Revision Number	Date	Changes
0	02/2003	Initial revision.
0.1	04/2003	Added pinout and pinout assignments table. Added the USB timing to Section 14. Added the Reduced MII to Section 15. Removed the Data Parity. Made some changes to the Features list.
0.2	05/2003	Made the changes to the RMII Timing, Made sure all the $V_{DDL}$ , $V_{DDH}$ , and GND show up on the pinout diagram. Changed the SPI Master Timing Specs. 162 and 164.
0.3	05/2003	Corrected the signals that had overlines on them.
0.4	5/2003	Changed the pin descriptions for PD8 and PD9.
0.5	5/2003	Changed some more typos, put in the phsel and phreq pins. Corrected the USB timing.
0.6	6/2003	Changed the pin descriptions per the June 22 spec.
0.7	7/2003	Added the RxClav and TxClav signals to PC15.
0.8	8/2003	Added the Reference to USB 2.0 to the Features list and removed 1.1 from USB on the block diagrams.
0.9	8/2003	Changed the USB description to full-/low-speed compatible.
1.0	9/2003	Added the DSP information in the Features list Fixed table formatting. Nontechnical edits. Released to the external web.
2.0	12/2003	Changed the maximum operating frequency to 133 MHz. Put in the orderable part numbers that are orderable. Put the timing in the 80 MHz column. Rounded the timings to hundredths in the 80 MHz column. Put the pin numbers in footnotes by the maximum currents in Table 6. Changed 22 and 41 in the Timing. Put in the Thermal numbers.
