Macronix

## FEATURES

## GENERAL

- Serial Peripheral Interface compatible -- Mode 0 and Mode 3
- 16M:16,777,216 x 1 bit structure or $8,388,608 \times 2$ bits (two I/O read mode) structure 32M:33,554,432 x 1 bit structure or 16,772,216 x 2 bits (two I/O read mode) structure 64M: $67,108,864 \times 1$ bit structure or $33,554,432 \times 2$ bits (two I/O read mode) structure
- 512 Equal Sectors with 4K byte each (16Mb)

1024 Equal Sectors with 4K byte each (32Mb)
2048 Equal Sectors with 4K byte each (64Mb)

- Any Sector can be erased individually
- 32 Equal Blocks with 64K byte each (16Mb)

64 Equal Blocks with 64K byte each (32Mb)
128 Equal Blocks with 64K byte each (64Mb)

- Any Block can be erased individually
- Single Power Supply Operation
- 2.7 to 3.6 volt for read, erase, and program operations
- Latch-up protected to 100 mA from -1 V to Vcc +1 V

## PERFORMANCE

- High Performance
- Fast access time: 86MHz serial clock
- Serial clock of two I/O read mode : 50 MHz , which is equivalent to 100 MHz
- Fast program time: 1.4 ms (typ.) and 5 ms (max.)/page (256-byte per page)
- Byte program time: 9us (typical)
- Continuously program mode (automatically increase address under word program mode)
- Fast erase time: 60ms(typ.) /sector (4K-byte per sector) ; 0.7s(typ.) /block (64K-byte per block); 14s(typ.) /chip for $16 \mathrm{Mb}, 25 \mathrm{~s}(\mathrm{typ}$.) for 32 Mb , and $50 \mathrm{~s}($ typ.) for 64 Mb
- Low Power Consumption
- Low active read current: 25 mA (max.) at 86 MHz , and 10 mA (max.) at 33 MHz
- Low active programming current: 20mA (max.)
- Low active erase current: 20 mA (max.)
- Low standby current: 20uA (max.)
- Deep power-down mode 1uA (typical)
- Typical 100,000 erase/program cycles
- 20 years of data retention

## SOFTWARE FEATURES

- Input Data Format
- 1-byte Command code
- Advanced Security Features
- Block lock protection

The BP0-BP3 status bit defines the size of the area to be software protection against program and erase instructions

- Additional 512-bit secured area for unique identifier
- Auto Erase and Auto Program Algorithm
- Automatically erases and verifies data at selected sector
- Automatically programs and verifies data at selected page by an internal algorithm that automatically times the program pulse widths (Any page to be programed should have page in the erased state first)

## - Status Register Feature

- Electronic Identification
- JEDEC 1-byte manufacturer ID and 2-byte device ID
- RES command for 1-byte Device ID
- Both REMS and REMS2 commands for 1-byte manufacturer ID and 1-byte device ID

## HARDWARE FEATURES

- SCLK Input
- Serial clock input
- SI Input
- Serial Data Input
- SO Output
- Serial Data Output
- WP\#/ACC pin
- Hardware write protection and program/erase acceleration
- HOLD\# pin
- pause the chip without diselecting the chip
- PACKAGE
- 16-pin SOP (300mil)
*- 8-land WSON (8x6mm or 6x5mm)
- 8-pin SOP (200mil, *150mil)
*- 8-pin PDIP ( 300 mil )
*- 8-land USON (4x4mm)
- All Pb-free devices are RoHS Compliant
* Advanced Information

## GENERAL DESCRIPTION

The MX25L1608D are $16,777,216$ bit serial Flash memory, which is configured as $2,097,152 \times 8$ internally. When it is in two I/O read mode, the structure becomes $8,388,608$ bits $\times 2$. The MX25L3208D are $33,554,432$ bit serial Flash memory, which is configured as $4,194,304 \times 8$ internally. When it is in two I/O read mode, the structure becomes $16,772,216$ bits $x 2$. The MX25L6408D are $67,108,864$ bit serial Flash memory, which is configured as $8,388,608$ $x 8$ internally. When it is in two I/O read mode, the structure becomes $33,554,432$ bits $\times 2$. (please refer to the "Two I/O Read mode" section). The MX25L1608D/3208D/6408D feature a serial peripheral interface and software protocol allowing operation on a simple 3 -wire bus. The three bus signals are a clock input (SCLK), a serial data input (SI), and a serial data output (SO). Serial access to the device is enabled by CS\# input.

When it is in two I/O read mode, the SI pin and SO pin become SIO0 pin and SIO1 pin for address/dummy bits input and data output.

The MX25L1608D/3208D/6408D provides sequential read operation on whole chip.
After program/erase command is issued, auto program/ erase algorithms which program/ erase and verify the specified page or sector/block locations will be executed. Program command is executed on byte basis, or page (256 bytes) basis, or word basis for Continuously program mode, and erase command is executes on sector (4K-byte), or block (64K-byte), or whole chip basis.

To provide user with ease of interface, a status register is included to indicate the status of the chip. The status read command can be issued to detect completion status of a program or erase operation via WIP bit.

Advanced security features enhance the protection and security functions, please see security features section for more details.

When the device is not in operation and CS\# is high, it is put in standby mode and draws less than 20uA DC current.

The MX25L1608D/3208D/6408D utilizes Macronix's proprietary memory cell, which reliably stores memory contents even after typical 100,000 program and erase cycles.

Table 1. Additional Feature Comparison

|  | Protection and Security |  | Read Performance | Identifier |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## DATA PROTECTION

The MX25L1608D/3208D/6408D is designed to offer protection against accidental erasure or programming caused by spurious system level signals that may exist during power transition. During power up the device automatically resets the state machine in the standby mode. In addition, with its control register architecture, alteration of the memory contents only occurs after successful completion of specific command sequences. The device also incorporates several features to prevent inadvertent write cycles resulting from VCC power-up and power-down transition or system noise.

- Valid command length checking: The command length will be checked whether it is at byte base and completed on byte boundary.
- Write Enable (WREN) command: WREN command is required to set the Write Enable Latch bit (WEL) before other command to change data. The WEL bit will return to reset stage under following situation:
- Power-up
- Write Disable (WRDI) command completion
- Write Status Register (WRSR) command completion
- Page Program (PP) command completion
- Continuously Program mode (CP) instruction completion
- Sector Erase (SE) command completion
- Block Erase (BE) command completion
- Chip Erase (CE) command completion
- Deep Power Down Mode: By entering deep power down mode, the flash device also is under protected from writing all commands except Release from deep power down mode command (RDP) and Read Electronic Signature command (RES).
- Advanced Security Features: there are some protection and securuity features which protect content from inadvertent write and hostile access.

## I. Block lock protection

- The Software Protected Mode (SPM) use (BP3, BP2, BP1, BP0) bits to allow part of memory to be protected as read only. The proected area definition is shown as table of "Protected Area Sizes", the protected areas are more flexible which may protect various area by setting value of BPO-BP3 bits.
Please refer to table of "protected area sizes".
- The Hardware Proteced Mode (HPM) use WP\#/ACC to protect the (BP3, BP2, BP1, BP0) bits and SRWD bit.

Table 2. Protected Area Sizes

| Status bit |  |  |  | Protect Level |  |  |  |
| :---: | :---: | :---: | :---: | :--- | :--- | :--- | :---: |
| BP3 | BP2 | BP1 | BP0 | 16Mb | 32Mb | 64Mb |  |
| 0 | 0 | 0 | 0 | 0 (none) | 0 (none) | 0 (none) |  |
| 0 | 0 | 0 | 1 | 1 (1block, block 31th) | 1 (1block, block 63th) | 1 (2block, block 126th-127th) |  |
| 0 | 0 | 1 | 0 | 2 (2blocks, block 30th-31th) | 2 (2blocks, block 62th-63th) | 2 (4blocks, block 124th-127th) |  |
| 0 | 0 | 1 | 1 | 3 (4blocks, block 28th-31th) | 3 (4blocks, block 60th-63th) | 3 (8blocks, block 120th-127th) |  |
| 0 | 1 | 0 | 0 | 4 (8blocks, block 24th-31th) | 4 (8blocks, block 56th-63th) | 4 (16blocks, block 112th-127th) |  |
| 0 | 1 | 0 | 1 | 5 (16blocks, block 16th-31th) | 5 (16blocks, block 48th-63th) | 5 (32blocks, block 96th-127th) |  |
| 0 | 1 | 1 | 0 | 6 (32blocks, all) | 6 (32blocks, block 32th-63th) | 6 (64blocks, block 64th-127th) |  |
| 0 | 1 | 1 | 1 | 7 (32blocks, all) | 7 (64blocks, all) | 7 (128blocks, all) |  |
| 1 | 0 | 0 | 0 | 8 (32blocks, all) | 8 (64blocks, all) | 8 (128blocks, all) |  |
| 1 | 0 | 0 | 1 | 9 (32blocks, all) | 9 (32blocks, block 0th-31th) | 9 (64blocks, Oth-63th) |  |
| 1 | 0 | 1 | 0 | 10 (16blocks, block 0th-15th) | 10 (48blocks, block 0th-47th) | 10 (96blocks, block 0th-95th) |  |
| 1 | 0 | 1 | 1 | 11 (24blocks, block 0th-23th) | 11 (56blocks, block 0th-55th) | 11 (112blocks, block 0th-111th) |  |
| 1 | 1 | 0 | 0 | 12 (28blocks, block 0th-27th) | 12 (60blocks, block 0th-59th) | $12(120$ blocks, block 0th-119th) |  |
| 1 | 1 | 0 | 1 | 13 (30blocks, block 0th-29th) | 13 (62blocks, block 0th-61th) | 13 (124blocks, block 0th-123th) |  |
| 1 | 1 | 1 | 0 | 14 (31blocks, block 0th-30th) | 14 (63blocks, block 0th-62th) | $14(126$ blocks, block 0th-125th) |  |
| 1 | 1 | 1 | 1 | 15 (32blocks, all) | 15 (64blocks, all) | 15 (128blocks, all) |  |

II. Additional 512-bit Secured Area for unique ID: to provide 512-bit read-only unique ID data. Please refer to table 3 . 512-bit secured area definition.

- Security register bit 0 indicates whether the chip is locked by factory or not.
- To read the 512-bit secured area by entering 512-bit secured area mode (with ENSA command), and going through normal read procedure, and then exiting 512-bit secured area mode by writing EXSA command.

Table 3. 512-bit Secured Area Definition

| Address range | Size | Standard Factory Lock |
| :---: | :---: | :---: |
| $x x x x 00 \sim x x x \times 3 F$ | 512 -bit | unique ID |

## HOLD FEATURES

HOLD\# pin signal goes low to hold any serial communications with the device. The HOLD feature will not stop the operation of write status register, programming, or erasing in progress.

The operation of HOLD requires Chip Select(CS\#) keeping low and starts on falling edge of HOLD\# pin signal while Serial Clock (SCLK) signal is being low (if Serial Clock signal is not being low, HOLD operation will not start until Serial Clock signal being low). The HOLD condition ends on the rising edge of HOLD\# pin signal while Serial Clock(SCLK) signal is being low( if Serial Clock signal is not being low, HOLD operation will not end until Serial Clock being low), see Figure 1.

Figure 1. Hold Condition Operation

The Serial Data Output (SO) is high impedance, both Serial Data Input (SI) and Serial Clock (SCLK) are don't care during the HOLD operation. If Chip Select (CS\#) drives high during HOLD operation, it will reset the internal logic of the device. To re-start communication with chip, the HOLD\# must be at high and CS\# must be at low.

## PROGRAM/ERASE ACCELERATION

To activate the program/erase acceleration function requires ACC pin connecting to $9.5 \sim 10.5 \mathrm{~V}$ voltage (see Figure 2), and then to be followed by the normal program/erase process. By utilizing the program/erase acceleration operation, the performances are improved as shown on table of "ERASE AND PROGRAM PERFORMACE".

After power-up ready, it should wait 10 ms at least to apply $\mathrm{VHH}(9.5 \sim 10.5 \mathrm{~V})$ on the WP\#/ACC pin.

Figure 2. ACCELERATED PROGRAM TIMING DIAGRAM

Note: tVHH (VHH Rise and Fall Time) min. 250ns

## DEVICE OPERATION

1. Before a command is issued, status register should be checked to ensure device is ready for the intended operation.
2. When incorrect command is inputted to this LSI, this LSI becomes standby mode and keeps the standby mode until next CS\# falling edge. In standby mode, SO pin of this LSI should be High-Z.
3. When correct command is inputted to this LSI, this LSI becomes active mode and keeps the active mode until next CS\# rising edge.
4. Input data is latched on the rising edge of Serial Clock(SCLK) and data shifts out on the falling edge of SCLK. The difference of Serial mode 0 and mode 3 is shown as Figure 3.
5. For the following instructions: RDID, RDSR, RDSCUR, READ, FAST_READ, 2READ, RES, REMS and REMS2 the shifted-in instruction sequence is followed by a data-out sequence. After any bit of data being shifted out, the CS\# can be high. For the following instructions: WREN, WRDI, WRSR, SE, BE, CE, PP, CP, RDP, DP, ENSA, EXSA, and WRSCUR, the CS\# must go high exactly at the byte boundary; otherwise, the instruction will be rejected and not executed.
6. During the progress of Write Status Register, Program, Erase operation, to access the memory array is neglected and not affect the current operation of Write Status Register, Program, Erase.

Figure 3. Serial Modes Supported

Note:
CPOL indicates clock polarity of Serial master, CPOL=1 for SCLK high while idle, CPOL=0 for SCLK low while not transmitting. CPHA indicates clock phase. The combination of CPOL bit and CPHA bit decides which Serial mode is supported.

## COMMAND DESCRIPTION

## (1) Write Enable (WREN)

The Write Enable (WREN) instruction is for setting Write Enable Latch (WEL) bit. For those instructions like PP, CP, SE, BE, CE, and WRSR, which are intended to change the device content, should be set every time after the WREN instruction setting the WEL bit.

The sequence of issuing WREN instruction is: CS\# goes low $\rightarrow$ sending WREN instruction code $\rightarrow$ CS\# goes high. (see Figure 12)

## (2) Write Disable (WRDI)

The Write Disable (WRDI) instruction is for resetting Write Enable Latch (WEL) bit.
The sequence of issuing WRDI instruction is: CS\# goes low $\rightarrow$ sending WRDI instruction code $\rightarrow$ CS\# goes high. (see Figure 13)

The WEL bit is reset by following situations:

- Power-up
- Write Disable (WRDI) instruction completion
- Write Status Register (WRSR) instruction completion
- Page Program (PP) instruction completion
- Sector Erase (SE) instruction completion
- Block Erase (BE) instruction completion
- Chip Erase (CE) instruction completion
- Continuously program mode (CP) instruction completion

## (3) Read Identification (RDID)

The RDID instruction is for reading the manufacturer ID of 1-byte and followed by Device ID of 2-byte. The MXIC Manufacturer ID is C2(hex), the memory type ID is 20(hex) as the first-byte device ID, and the individual device ID of second-byte ID are listed as table of "ID Definitions".

The sequence of issuing RDID instruction is: CS\# goes low $\rightarrow$ sending RDID instruction code $\rightarrow 24$-bits ID data out on SO $\rightarrow$ to end RDID operation can use CS\# to high at any time during data out. (see Figure. 14)

While Program/Erase operation is in progress, it will not decode the RDID instruction, so there's no effect on the cycle of program/erase operation which is currently in progress. When CS\# goes high, the device is at standby stage.

## (4) Read Status Register (RDSR)

The RDSR instruction is for reading Status Register Bits. The Read Status Register can be read at any time (even in program/erase/write status register condition) and continuously. It is recommended to check the Write in Progress (WIP) bit before sending a new instruction when a program, erase, or write status register operation is in progress.

The sequence of issuing RDSR instruction is: CS\# goes low $\rightarrow$ sending RDSR instruction code $\rightarrow$ Status Register data out on SO (see Figure. 15)

The definition of the status register bits is as below:
WIP bit. The Write in Progress (WIP) bit, a volatile bit, indicates whether the device is busy in program/erase/write status register progress. When WIP bit sets to 1, which means the device is busy in program/erase/write status register progress. When WIP bit sets to 0 , which means the device is not in progress of program/erase/write status register cycle.

WEL bit. The Write Enable Latch (WEL) bit, a volatile bit, indicates whether the device is set to internal write enable latch. When WEL bit sets to 1 , which means the internal write enable latch is set, the device can accept program/ erase/write status register instruction. When WEL bit sets to 0 , which means no internal write enable latch; the device will not accept program/erase/write status register instruction. The program/erase command will be ignored and not affect value of WEL bit if it is applied to a protected memory area.

BP3, BP2, BP1, BP0 bits. The Block Protect (BP3, BP2, BP1, BP0) bits, non-volatile bits, indicate the protected area(as defined in table 1) of the device to against the program/erase instruction without hardware protection mode being set. To write the Block Protect (BP3, BP2, BP1, BP0) bits requires the Write Status Register (WRSR) instruction to be executed. Those bits define the protected area of the memory to against Page Program (PP), Sector Erase (SE), Block Erase (BE) and Chip Erase(CE) instructions (only if all Block Protect bits set to 0, the CE instruction can be executed).

Continuously Program Mode( CP mode) bit. The Continuously Program Mode bit indicates the status of CP mode, " 0 " indicates not in CP mode; "1" indicates in CP mode.

SRWD bit. The Status Register Write Disable (SRWD) bit, non-volatile bit, is operated together with Write Protection (WP\#/ACC) pin for providing hardware protection mode. The hardware protection mode requires SRWD sets to 1 and WP\#/ACC pin signal is low stage. In the hardware protection mode, the Write Status Register (WRSR) instruction is no longer accepted for execution and the SRWD bit and Block Protect bits (BP3, BP2, BP1, BP0) are read only.

## Status Register

| bit7 | bit6 | bit5 | bit4 | bit3 | bit2 | bit1 | bit0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| SRWD (status register write protect) | Continuously program mode (CP mode) | BP3 <br> (level of protected block) | BP2 <br> (level of protected block) | BP1 <br> (level of protected block) | BPO <br> (level of protected block) | WEL <br> (write enable latch) | WIP (write in progress bit) |
| 1=status register write disable | 1=nprmal program mode $0=$ CP mode (default) | (note 1) | (note 1) | (note 1) | (note 1) | ```1=write enable 0=not write enable``` | 1=write operation $0=$ not in write operation |
| Non-volatile bit | volatile bit | Non-volatile bit | Non-volatile bit | Non-volatile bit | Non-volatile bit | volatile bit | volatile bit |

Note 1: see the table 2 "Protected Area Size".

## (5) Write Status Register (WRSR)

The WRSR instruction is for changing the values of Status Register Bits. Before sending WRSR instruction, the Write Enable (WREN) instruction must be decoded and executed to set the Write Enable Latch (WEL) bit in advance. The WRSR instruction can change the value of Block Protect (BP3, BP2, BP1, BP0) bits to define the protected area of memory (as shown in table 1). The WRSR also can set or reset the Status Register Write Disable (SRWD) bit in accordance with Write Protection (WP\#/ACC) pin signal. The WRSR instruction cannot be executed once the Hardware Protected Mode (HPM) is entered.

The sequence of issuing WRSR instruction is: CS\# goes low $\rightarrow$ sending WRSR instruction code $\rightarrow$ Status Register data on $\mathrm{SI} \rightarrow$ CS\# goes high. (see Figure 16)

The WRSR instruction has no effect on $\mathrm{b} 6, \mathrm{~b} 1, \mathrm{~b} 0$ of the status register.
The CS\# must go high exactly at the byte boundary; otherwise, the instruction will be rejected and not executed. The self-timed Write Status Register cycle time (tW) is initiated as soon as Chip Select (CS\#) goes high. The Write in Progress (WIP) bit still can be check out during the Write Status Register cycle is in progress. The WIP sets 1 during the tW timing, and sets 0 when Write Status Register Cycle is completed, and the Write Enable Latch (WEL) bit is reset.

Table 6. Protection Modes

| Mode | Status register condition | WP\# and SRWD bit status | Memory |
| :---: | :---: | :---: | :---: |
| Software protection <br> mode (SPM) | Status register can be written <br> in (WEL bit is set to "1") and <br> the SRWD, BP0-BP3 <br> bits can be changed | WP\#=1 and SRWD bit=0, or <br> WP\#=0 and SRWD bit=0, or <br> WP\#=1 and SRWD=1 | The protected area <br> cannot <br> be program or erase. |
| Hardware protection <br> mode (HPM) | The SRWD, BP0-BP3 of <br> status register bits cannot be <br> changed | WP\#=0, SRWD bit=1 | The protected area <br> cannot <br> be program or erase. |

Note:

1. As defined by the values in the Block Protect (BP3, BP2, BP1, BPO) bits of the Status Register, as shown in Table 1.

As the above table showing, the summary of the Software Protected Mode (SPM) and Hardware Protected Mode (HPM).
Software Protected Mode (SPM):

- When SRWD bit=0, no matter WP\#/ACC is low or high, the WREN instruction may set the WEL bit and can change the values of SRWD, BP3, BP2, BP1, BP0. The protected area, which is defined by BP3, BP2, BP1, BPO, is at software protected mode (SPM).
- When SRWD bit=1 and WP\#/ACC is high, the WREN instruction may set the WEL bit can change the values of SRWD, BP3, BP2, BP1, BP0. The protected area, which is defined by $B P 3, B P 2, B P 1, B P 0$, is at software protected mode (SPM)

Note: If SRWD bit=1 but WP\#/ACC is low, it is impossible to write the Status Register even if the WEL bit has previously been set. It is rejected to write the Status Register and not be executed.

Hardware Protected Mode (HPM):

- When SRWD bit=1, and then WP\#/ACC is low (or WP\#/ACC is low before SRWD bit=1), it enters the hardware protected mode (HPM). The data of the protected area is protected by software protected mode by BP3, BP2, BP1, BP0 and hardware protected mode by the WP\#/ACC to against data modification.

Note: to exit the hardware protected mode requires WP\#/ACC driving high once the hardware protected mode is entered. If the WP\#/ACC pin is permanently connected to high, the hardware protected mode can never be entered; only can use software protected mode via BP3, BP2, BP1, BP0.

## (6) Read Data Bytes (READ)

The read instruction is for reading data out. The address is latched on rising edge of SCLK, and data shifts out on the falling edge of SCLK at a maximum frequency fR. The first address byte can be at any location. The address is automatically increased to the next higher address after each byte data is shifted out, so the whole memory can be read out at a single READ instruction. The address counter rolls over to 0 when the highest address has been reached.

The sequence of issuing READ instruction is: CS\# goes low $\rightarrow$ sending READ instruction code $\rightarrow 3$-byte address on $\mathrm{SI} \rightarrow$ data out on SO $\rightarrow$ to end READ operation can use CS\# to high at any time during data out. (see Figure. 17)

## (7) Read Data Bytes at Higher Speed (FAST_READ)

The FAST_READ instruction is for quickly reading data out. The address is latched on rising edge of SCLK, and data of each bit shifts out on the falling edge of SCLK at a maximum frequency fC. The first address byte can be at any location. The address is automatically increased to the next higher address after each byte data is shifted out, so the whole memory can be read out at a single FAST_READ instruction. The address counter rolls over to 0 when the highest address has been reached.

The sequence of issuing FAST_READ instruction is: CS\# goes low $\rightarrow$ sending FAST_READ instruction code $\rightarrow$ 3-byte address on $\mathrm{SI} \rightarrow$ 1-dummy byte address on $\mathrm{SI} \rightarrow$ data out on $\mathrm{SO} \rightarrow$ to end FAST_READ operation can use CS\# to high at any time during data out. (see Figure. 18)

While Program/Erase/Write Status Register cycle is in progress, FAST_READ instruction is rejected without any impact on the Program/Erase/Write Status Register current cycle.

## (8) $\mathbf{2 x ~ I / O ~ R e a d ~ M o d e ~ ( 2 R E A D ) ~}$

The 2READ instruction enable double throughput of Serial Flash in read mode. The address is latched on rising edge of SCLK, and data of every two bits(interleave on 2 I/O pins) shift out on the falling edge of SCLK at a maximum frequency fT . The first address byte can be at any location. The address is automatically increased to the next higher address after each byte data is shifted out, so the whole memory can be read out at a single 2READ instruction. The address counter rolls over to 0 when the highest address has been reached. Once writing 2READ instruction, the following address/dummy/data out will perform as 2-bit instead of previous 1-bit.

The sequence of issuing 2READ instruction is: CS\# goes low $\rightarrow$ sending 2READ instruction $\rightarrow 24$-bit address interleave on $\mathrm{SIO} 1 \& \mathrm{SIO} \rightarrow$ 8-bit dummy interleave on $\mathrm{SIO} 1 \& \mathrm{SIO} \rightarrow$ data out interleave on SIO \& $\mathrm{SIO} \rightarrow$ to end 2READ operation can use CS\# to high at any time during data out (see Figure of $2 \times \mathrm{I} / \mathrm{O}$ Read Mode Timing Waveform)

While Program/Erase/Write Status Register cycle is in progress, 2READ instruction is rejected without any impact on the Program/Erase/Write Status Register current cycle.

The 2 I/O only perform read operation. Program/Erase /Read ID/Read status/Read ID....operation do not support 2 I/O throughputs.

## (9) Sector Erase (SE)

The Sector Erase (SE) instruction is for erasing the data of the chosen sector to be "1". The instruction is used for any 4K-byte sector. A Write Enable (WREN) instruction must execute to set the Write Enable Latch (WEL) bit before sending the Sector Erase (SE). Any address of the sector (see table 3) is a valid address for Sector Erase (SE) instruction. The CS\# must go high exactly at the byte boundary (the latest eighth of address byte been latched-in); otherwise, the instruction will be rejected and not executed.

Address bits [Am-A12] (Am is the most significant address) select the sector address.
The sequence of issuing SE instruction is: CS\# goes low $\rightarrow$ sending SE instruction code $\rightarrow 3$-byte address on SI $\rightarrow$ CS\# goes high. (see Figure 22)

The self-timed Sector Erase Cycle time (tSE) is initiated as soon as Chip Select (CS\#) goes high. The Write in Progress (WIP) bit still can be check out during the Sector Erase cycle is in progress. The WIP sets 1 during the tSE timing, and sets 0 when Sector Erase Cycle is completed, and the Write Enable Latch (WEL) bit is reset. If the page is protected by BP3, BP2, BP1, BP0 bits, the Sector Erase (SE) instruction will not be executed on the page.

## (10) Block Erase (BE)

The Block Erase (BE) instruction is for erasing the data of the chosen block to be "1". The instruction is used for 64K-byte sector erase operation. A Write Enable (WREN) instruction must execute to set the Write Enable Latch (WEL) bit before sending the Block Erase (BE). Any address of the block (see table 3 ) is a valid address for Block Erase (BE) instruction. The CS\# must go high exactly at the byte boundary (the latest eighth of address byte been latched-in); otherwise, the instruction will be rejected and not executed.

The sequence of issuing BE instruction is: CS\# goes low $\rightarrow$ sending BE instruction code $\rightarrow 3$-byte address on $\mathrm{SI} \rightarrow$ CS\# goes high. (see Figure 23)

The self-timed Block Erase Cycle time (tBE) is initiated as soon as Chip Select (CS\#) goes high. The Write in Progress (WIP) bit still can be check out during the Sector Erase cycle is in progress. The WIP sets 1 during the tBE timing, and sets 0 when Sector Erase Cycle is completed, and the Write Enable Latch (WEL) bit is reset. If the page is protected by BP3, BP2, BP1, BP0 bits, the Block Erase (BE) instruction will not be executed on the page.

## (11) Chip Erase (CE)

The Chip Erase (CE) instruction is for erasing the data of the whole chip to be "1". A Write Enable (WREN) instruction must execute to set the Write Enable Latch (WEL) bit before sending the Chip Erase (CE). Any address of the sector (see table 3) is a valid address for Chip Erase (CE) instruction. The CS\# must go high exactly at the byte boundary( the latest eighth of address byte been latched-in); otherwise, the instruction will be rejected and not executed.

The sequence of issuing CE instruction is: CS\# goes low $\rightarrow$ sending CE instruction code $\rightarrow$ CS\# goes high. (see Figure 24)

The self-timed Chip Erase Cycle time (tCE) is initiated as soon as Chip Select (CS\#) goes high. The Write in Progress (WIP) bit still can be check out during the Chip Erase cycle is in progress. The WIP sets 1 during the tCE timing, and sets 0 when Chip Erase Cycle is completed, and the Write Enable Latch (WEL) bit is reset. If the chip is protected by BP3, BP2, BP1, BP0 bits, the Chip Erase (CE) instruction will not be executed. It will be only executed when BP3, BP2, BP1, BP0 all set to "0".

## (12) Page Program (PP)

The Page Program (PP) instruction is for programming the memory to be " 0 ". A Write Enable (WREN) instruction must execute to set the Write Enable Latch (WEL) bit before sending the Page Program (PP). If the eight least significant address bits (A7-A0) are not all 0, all transmitted data which goes beyond the end of the current page are programmed from the start address if the same page (from the address whose 8 least significant address bits (A7A0) are all 0). The CS\# must keep during the whole Page Program cycle. The CS\# must go high exactly at the byte boundary( the latest eighth of address byte been latched-in); otherwise, the instruction will be rejected and not executed. If more than 256 bytes are sent to the device, the data of the last 256 -byte is programmed at the request page and previous data will be disregarded. If less than 256 bytes are sent to the device, the data is programmed at the request address of the page without effect on other address of the same page.

The sequence of issuing PP instruction is: CS\# goes low $\rightarrow$ sending PP instruction code $\rightarrow$ 3-byte address on $\mathrm{SI} \rightarrow$ at least 1-byte on data on SI $\rightarrow$ CS\# goes high. (see Figure 20)

The self-timed Page Program Cycle time (tPP) is initiated as soon as Chip Select (CS\#) goes high. The Write in Progress (WIP) bit still can be check out during the Page Program cycle is in progress. The WIP sets 1 during the tPP timing, and sets 0 when Page Program Cycle is completed, and the Write Enable Latch (WEL) bit is reset. If the page is protected by BP3, BP2, BP1, BP0 bits, the Page Program (PP) instruction will not be executed.

## (13) Continuously program mode (CP mode)

The CP mode may enhance program performance by automatically increasing address to the next higher address after each byte data has been programmed.

The Continuously program (CP) instruction is for multiple byte program to Flash. A write Enable (WREN) instruction must execute to set the Write Enable Latch(WEL) bit before sending the Continuously program (CP) instruction. CS\# requires to go high before CP instruction is executing. After CP instruction and address input, two bytes of data is input sequentially from MSB(bit7) to LSB(bit0). The first byte data will be programmed to the initial address range with $A 0=0$ and second byte data with $A 0=1$. If only one byte data is input, the $C P$ mode will not process. If more than two bytes data are input, the additional data will be ignored and only two byte data are valid. The CP program instruction will be ignored and not affect the WEL bit if it is applied to a protected memory area. Any byte to be programmed should be in the erase state (FF) first. It will not roll over during the CP mode, once the last unprotected address has been reached, the chip will exit CP mode and reset write Enable Latch bit (WEL) as "0" and CP mode bit as " 0 ". Please check the WIP bit status if it is not in write progress before entering next valid instruction. During CP mode, the valid commands are CP command (AD hex), WRDI command ( 04 hex), RDSR command ( 05 hex), RDPR command (A1 hex), and RDSCUR command (2B hex). And the WRDI command is valid after completion of a CP programming cycle, which means the WIP bit=0.

The sequence of issuing CP instruction is : CS\# high to low $\rightarrow$ sending CP instruction code $\rightarrow 3$-byte address on $\mathrm{SI} \rightarrow$ Data Byte on SI $\rightarrow$ CS\# goes high to low $\rightarrow$ sending CP instruction...... $\rightarrow$ last desired byte programmed or sending Write Disable (WRDI) instruction to end CP mode $\rightarrow$ sending RDSR instruction to verify if CP mode is ended. (see Figure of CP mode timing waveform)

Three methods to detect the completion of a program cycle during CP mode:

1) Software method-I: by checking WIP bit of Status Register to detect the completion of CP mode.
2) Software method-II: by waiting for a tBP time out to determine if it may load next valid command or not.
3) Hardware method: by writing ESRY (enable SO to output RY/BY\#) instruction to detect the completion of a program cycle during CP mode. The ESRY instruction must be executed before CP mode execution. Once it is enable in CP mode, the CS\# goes low will drive out the RY/BY\# status on SO, " 0 " indicates busy stage, " 1 " indicates ready stage, SO pin outputs tri-state if CS\# goes high. DSRY (disable SO to output RY/BY\#) instruction to disable the SO to output RY/BY\# and return to status register data output during CP mode. Please note that the ESRY/DSRY command are not accepted unless the completion of CP mode.

## (14) Deep Power-down (DP)

The Deep Power-down (DP) instruction is for setting the device on the minimizing the power consumption (to entering the Deep Power-down mode), the standby current is reduced from ISB1 to ISB2). The Deep Power-down mode requires the Deep Power-down (DP) instruction to enter, during the Deep Power-down mode, the device is not active and all Write/Program/Erase instruction are ignored. When CS\# goes high, it's only in standby mode not deep power-down mode. It's different from Standby mode.

The sequence of issuing DP instruction is: CS\# goes low $\rightarrow$ sending DP instruction code $\rightarrow$ CS\# goes high. (see Figure 25)

Once the DP instruction is set, all instruction will be ignored except the Release from Deep Power-down mode (RDP) and Read Electronic Signature (RES) instruction. (those instructions allow the ID being reading out). When Powerdown, the deep power-down mode automatically stops, and when power-up, the device automatically is in standby mode. For RDP instruction the CS\# must go high exactly at the byte boundary (the latest eighth bit of instruction code been latched-in); otherwise, the instruction will not executed. As soon as Chip Select (CS\#) goes high, a delay of tDP is required before entering the Deep Power-down mode and reducing the current to ISB2.

## (15) Release from Deep Power-down (RDP), Read Electronic Signature (RES)

The Release from Deep Power-down (RDP) instruction is terminated by driving Chip Select (CS\#) High. When Chip Select (CS\#) is driven High, the device is put in the Stand-by Power mode. If the device was not previously in the Deep Power-down mode, the transition to the Stand-by Power mode is immediate. If the device was previously in the Deep Power-down mode, though, the transition to the Stand-by Power mode is delayed by tRES2, and Chip Select (CS\#) must remain High for at least tRES2(max), as specified in Table 6. Once in the Stand-by Power mode, the device waits to be selected, so that it can receive, decode and execute instructions.

RES instruction is for reading out the old style of 8-bit Electronic Signature, whose values are shown as table of ID Definitions. This is not the same as RDID instruction. It is not recommended to use for new design. For new design, please use RDID instruction. Even in Deep power-down mode, the RDP and RES are also allowed to be executed, only except the device is in progress of program/erase/write cycle; there's no effect on the current program/erase/ write cycle in progress.

The sequence is shown as Figure 26,27.
The RES instruction is ended by CS\# goes high after the ID been read out at least once. The ID outputs repeatedly if continuously send the additional clock cycles on SCLK while CS\# is at low. If the device was not previously in Deep Power-down mode, the device transition to standby mode is immediate. If the device was previously in Deep Power-down mode, there's a delay of tRES2 to transit to standby mode, and CS\# must remain to high at least tRES2(max). Once in the standby mode, the device waits to be selected, so it can be receive, decode, and execute instruction.

The RDP instruction is for releasing from Deep Power Down Mode.

## (16) Read Electronic Manufacturer ID \& Device ID (REMS), (REMS2)

The REMS \& REMS2 instruction is an alternative to the Release from Power-down/Device ID instruction that provides both the JEDEC assigned manufacturer ID and the specific device ID.

The REMS \& REMS2 instruction is very similar to the Release from Power-down/Device ID instruction. The instruction is initiated by driving the CS\# pin low and shift the instruction code " 90 h " or "EFh" followed by two dummy bytes and one bytes address (A7~A0). After which, the Manufacturer ID for MXIC (C2h) and the Device ID are shifted out on the falling edge of SCLK with most significant bit (MSB) first as shown in figure 25. The Device ID values are listed in Table of ID Definitions. If the one-byte address is initially set to 01 h , then the device ID will be read first and then followed by the Manufacturer ID. The Manufacturer and Device IDs can be read continuously, alternating from one to the other. The instruction is completed by driving CS\# high.

Table 7. ID Definitions

| Command Type | MX25L1608D |  |  | MX25L3208D |  |  | MX25L6408D |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| RDID Command | $\begin{gathered} \text { manufacturer } \\ \text { ID } \end{gathered}$ | memory type | memory density | $\begin{array}{\|c} \text { manufacturer } \\ \text { ID } \end{array}$ | memory type | memory density | $\left\lvert\, \begin{gathered} \text { manufacturer } \\ \text { ID } \end{gathered}\right.$ | memory type | memory density |
|  | C2 | 20 | 15 | C2 | 20 | 16 | C2 | 20 | 17 |
| RES Command | electronic ID |  |  | electronic ID |  |  | electronic ID |  |  |
|  | 14 |  |  | 15 |  |  | 16 |  |  |
| REMS/REMS2 | $\begin{array}{\|c\|} \hline \text { manufacturer } \\ \text { ID } \end{array}$ | device ID |  | $\begin{array}{\|c} \text { manufacturer } \\ \text { ID } \end{array}$ | device ID |  | $\begin{array}{\|c\|} \hline \begin{array}{c} \text { manufacturer } \\ \text { ID } \end{array} \\ \hline \end{array}$ | device ID |  |
|  | C2 | 14 |  | C2 | 15 |  | C2 | 16 |  |

## (17) Enter Secured Area (ENSA)

The ENSA instruction is for entering the additional 512-bit secured area mode. The additional 512-bit secured area is independent from main array, which is used to store unique ID for system identifier. After entering the Secured Area mode, follow standard read or program procedure to read out the data.

The sequence of issuing ENSA instruction is: CS\# goes low $\rightarrow$ sending ENSA instruction to enter Secured Area mode $\rightarrow$ CS\# goes high.

Please note that WRSR/WRSCUR commands are not acceptable during the access of secure area region.

## (18) Exit Secured Area (EXSA)

The EXSA instruction is for exiting the additional 512 -bit secured area mode.
The sequence of issuing EXSA instruction is: CS\# goes low $\rightarrow$ sending EXSA instruction to exit Secured Area mode $\rightarrow$ CS\# goes high.

## (19) Read Security Register (RDSCUR)

The RDSCUR instruction is for reading the value of Security Register bits. The Read Security Register can be read at any time (even in program/erase/write status register/write security register condition) and continuously.

The sequence of issuing RDSCUR instruction is : CS\# goes low $\rightarrow$ send ing RDSCUR instruction $\rightarrow$ Security Register data out on SO $\rightarrow$ CS\# goes high.

The definition of the Security Register bits is as below:
Secured Area Indicator bit. The Secured Area indicator bit shows the chip is locked by factory before ex- factory or not. When it is " 0 ", it indicates non- factory lock; "1" indicates factory- lock.

Table 8. Security Register Definition

| bit7 | bit6 | bit5 | bit4 | bit3 | bit2 | bit1 | bit0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| x | x | x | x | x | x | x | Secured Area <br> indicator bit |
| reserved | reserved | reserved | reserved | reserved | reserved | reserved | $1=$ factory <br> lock (default) |
| volatile bit | volatile bit | volatile bit | volatile bit | volatile bit | volatile bit | volatile bit | Non-volatile bit |

## (20) Write Security Register (WRSCUR)

The WRSCUR instruction is for changing the values of Security Register Bits. Unlike write status register, the WREN instruction is not required before sending WRSCUR instruction.

The sequence of issuing WRSCUR instruction is :CS\# goes low $\rightarrow$ sending WRSCUR instruction $\rightarrow$ CS\# goes high.
The CS\# must go high exactly at the boundary; otherwise, the instruction will be rejected and not executed.

## POWER-ON STATE

The device is at below states when power-up:

- Standby mode ( please note it is not deep power-down mode)
- Write Enable Latch (WEL) bit is reset

The device must not be selected during power-up and power-down stage unless the VCC achieves below correct level:

- VCC minimum at power-up stage and then after a delay of tVSL
- GND at power-down

Please note that a pull-up resistor on CS\# may ensure a safe and proper power-up/down level.
An internal power-on reset (POR) circuit may protect the device from data corruption and inadvertent data change during power up state.

For further protection on the device, if the VCC does not reach the VCC minimum level, the correct operation is not guaranteed. The read, write, erase, and program command should be sent after the below time delay:

- tVSL after VCC reached VCC minimum level

The device can accept read command after VCC reached VCC minimum and a time delay of tVSL.
Please refer to the figure of "power-up timing".
Note:

- To stabilize the VCC level, the VCC rail decoupled by a suitable capacitor close to package pins is recommended.(generally around 0.1 uF )

## ELECTRICAL SPECIFICATIONS

ABSOLUTE MAXIMUM RATINGS

| RATING | VALUE |
| :--- | :--- |
| Ambient Operating Temperature | $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$ for Industrial grade |
| Storage Temperature | $-55^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ |
| Applied Input Voltage | -0.5 V to 4.6 V |
| Applied Output Voltage | -0.5 V to 4.6 V |
| VCC to Ground Potential | -0.5 V to 4.6 V |

## NOTICE:

1. Stresses greater than those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent damage to the device. This is stress rating only and functional operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended period may affect reliability.
2. Specifications contained within the following tables are subject to change.
3. During voltage transitions, all pins may overshoot Vss to -2.0 V and Vcc to +2.0 V for periods up to 20 ns , see Figure 4,5 .

|  |  |  | 16Mb |  | 14 | 30 | s |

Notes:

1. $\mathrm{tCH}+\mathrm{tCL}$ must be greater than or equal to $1 / \mathrm{f}$ ( fC or fR ).
2. Value guaranteed by characterization, not $100 \%$ tested in production.
3. Expressed as a slew-rate.
4. Only applicable as a constraint for a WRSR instruction when SRWD is set at 1.
5. Test condition is shown as Figure 6.

Table 11. Power-Up Timing

| Symbol | Parameter | Min. | Max. | Unit |
| :--- | :--- | :---: | :---: | :---: |
| $\mathrm{tVSL}(1)$ | VCC(min) to CS\# low | 200 |  | us |

Note: 1 . The parameter is characterized only.

## INITIAL DELIVERY STATE

The device is delivered with the memory array erased: all bits are set to 1 (each byte contains FFh). The Status Register contains 00h (all Status Register bits are 0).

Figure 8. Serial Input Timing

Figure 9. Output Timing

Figure 10. Hold Timing

* SI is "don't care" during HOLD operation.

Figure 21. Continously Program (CP) Mode Sequence with Hardware Detection (Command AD)

Note: (1) During CP mode, the valid commands are CP command (AD hex), WRDI command (04 hex), RDSR command ( 05 hex), RDPR command (A1 hex), and RDSCUR command (2B hex).
(2) Once an internal programming operation begins, CS\# goes low will drive the status on the SO pin and CS\# goes high will return the SO pin to tri-state.
(3) To end the CP mode, either reaching the highest unprotected address or sending Write Disable (WRDI) command ( 04 hex) may achieve it and then it is recommended to send RDSR command ( 05 hex) to verify if CP mode ends.

## RECOMMENDED OPERATING CONDITIONS

## At Device Power-Up

AC timing illustrated in Figure $A$ is recommended for the supply voltages and the control signals at device power-up. If the timing in the figure is ignored, the device may not operate correctly.

Figure A. AC Timing at Device Power-Up

| Symbol | Parameter | Notes | Min. | Max. | Unit |
| :---: | :--- | :---: | :---: | :---: | :---: |
| tVR | VCC Rise Time | 1 | 20 | 500000 | us/V |

Notes:

1. Sampled, not $100 \%$ tested.
2. For AC spec tCHSL, tSLCH, tDVCH, tCHDX, tSHSL, tCHSH, tSHCH, tCHCL, tCLCH in the figure, please refer to "AC CHARACTERISTICS" table.

Macronix

ERASE AND PROGRAMMING PERFORMANCE

| PARAMETER | Min. | TYP. (1) | Max. (2) | UNIT |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Write Status Register Cycle Time |  | 7 | 100 | ms |  |
| Sector Erase Cycle Time |  | 60 | 300 | ms |  |
| Block Erase Cycle Time |  | 0.7 | 2 | s |  |
| Chip Erase Cycle Time | 64 Mb |  | 42 | 80 | s |
|  | 32 Mb |  | 23 | 50 | s |
|  | 16 Mb |  | 14 | 30 | s |
| Chip Erase Cycle Time (at ACC mode) | 64 Mb |  | 30 | 48 | s |
|  | 32 Mb |  | 15 | 30 | s |
|  | 16 Mb |  | 8 | 18 | s |
| Byte Program Time (via page program command) |  | 9 | 300 | us |  |
| Page Program Cycle Time |  | 1.4 | 5 | ms |  |
| Page Program Cycle Time (at ACC mode) |  | 1.4 | 5 | ms |  |
| Erase/Program Cycle |  | 100,000 |  | cycles |  |

Note:

1. Typical program and erase time assumes the following conditions: $25^{\circ} \mathrm{C}, 3.3 \mathrm{~V}$, and checker board pattern.
2. Under worst conditions of $85^{\circ} \mathrm{C}$ and 2.7 V .
3. System-level overhead is the time required to execute the first-bus-cycle sequence for the programming command.
4. Erase/Program cycles comply with JEDEC JESD-47E \& A117A standard.

## Data Retention

| PARAMETER | Condition | Min. | Max. | UNIT |
| :---: | :---: | :---: | :---: | :---: |
| Data retention | $55^{\circ} \mathrm{C}$ | 20 |  | years |

## LATCH-UP CHARACTERISTICS

|  | MIN. | MAX. |
| :--- | :---: | :---: |
| Input Voltage with respect to GND on ACC | -1.0 V | 10.5 V |
| Input Voltage with respect to GND on all power pins, SI, CS\# | -1.0 V | 2 VCCmax |
| Input Voltage with respect to GND on SO | -1.0 V | VCC +1.0 V |
| Current | -100 mA | +100 mA |
| Includes all pins except VCC. Test conditions: VCC $=3.0 \mathrm{~V}$, one pin at a time. |  |  |
